These symbols give the following information: A trolley line and a telephone circuit enter the drift mouth and run along the main entry as far as No. 1 North, into which they both turn, and along which they both are carried as far as the parting between No. 8 and No. 9 West, at which point the trolley and the telephone lines stop and a circuit of two bare conductors begins. This circuit runs as far as No. 14 West with branches in-

are located a switchboard, a telephone and four incandescent lamps.

The mine is shown with an electrically operated fan. At the fan house the symbols show a high-voltage transmission line and lightning arresters, a 150-hp. low-voltage alternating-current motor, a 150 kw. transformer, a switchboard and incandescent lights. Marginal note No. 2 gives some additional information regarding the motor.

The symbols show that in pump room No. 1 are located a 50-hp. direct-current motor of the open type, a switchboard, a telephone and four incandescent lights.

There is also a symbol which shows that the return circuit of the motor is grounded to the pipe line leading from the pump.

In pump room No. 2 are located a high-voltage alternating-current motor of 100 hp. capacity, a switchboard, a telephone and four incandescent lights. There is a high-tension transmission line on the surface which supplies power from a high-voltage leaded cable leading to

Wired for Signal Lamps and Shot Firing

This mine is supposed to use a good deal of miscellaneous apparatus not used in the mine just discussed; for instance, signal lights are shown at almost every junction of a side entry with the main haulageway. Automatic trolley switches or section insulators with single-pole switches are used on every side entry where motors are operating. This mine trolley wires, a telephone wire and a short-firing line running along the main entry. The second symbol shows that a signal line has been added for operating the signal light in No. 1 North. As we turn into No. 1 North at its junction with the main entry the first symbol shows that a trolley line, a signal circuit, a telephone circuit, a bare low-voltage conductor and a shot-firing circuit are running down this entry. The next symbol marks the point where the signal

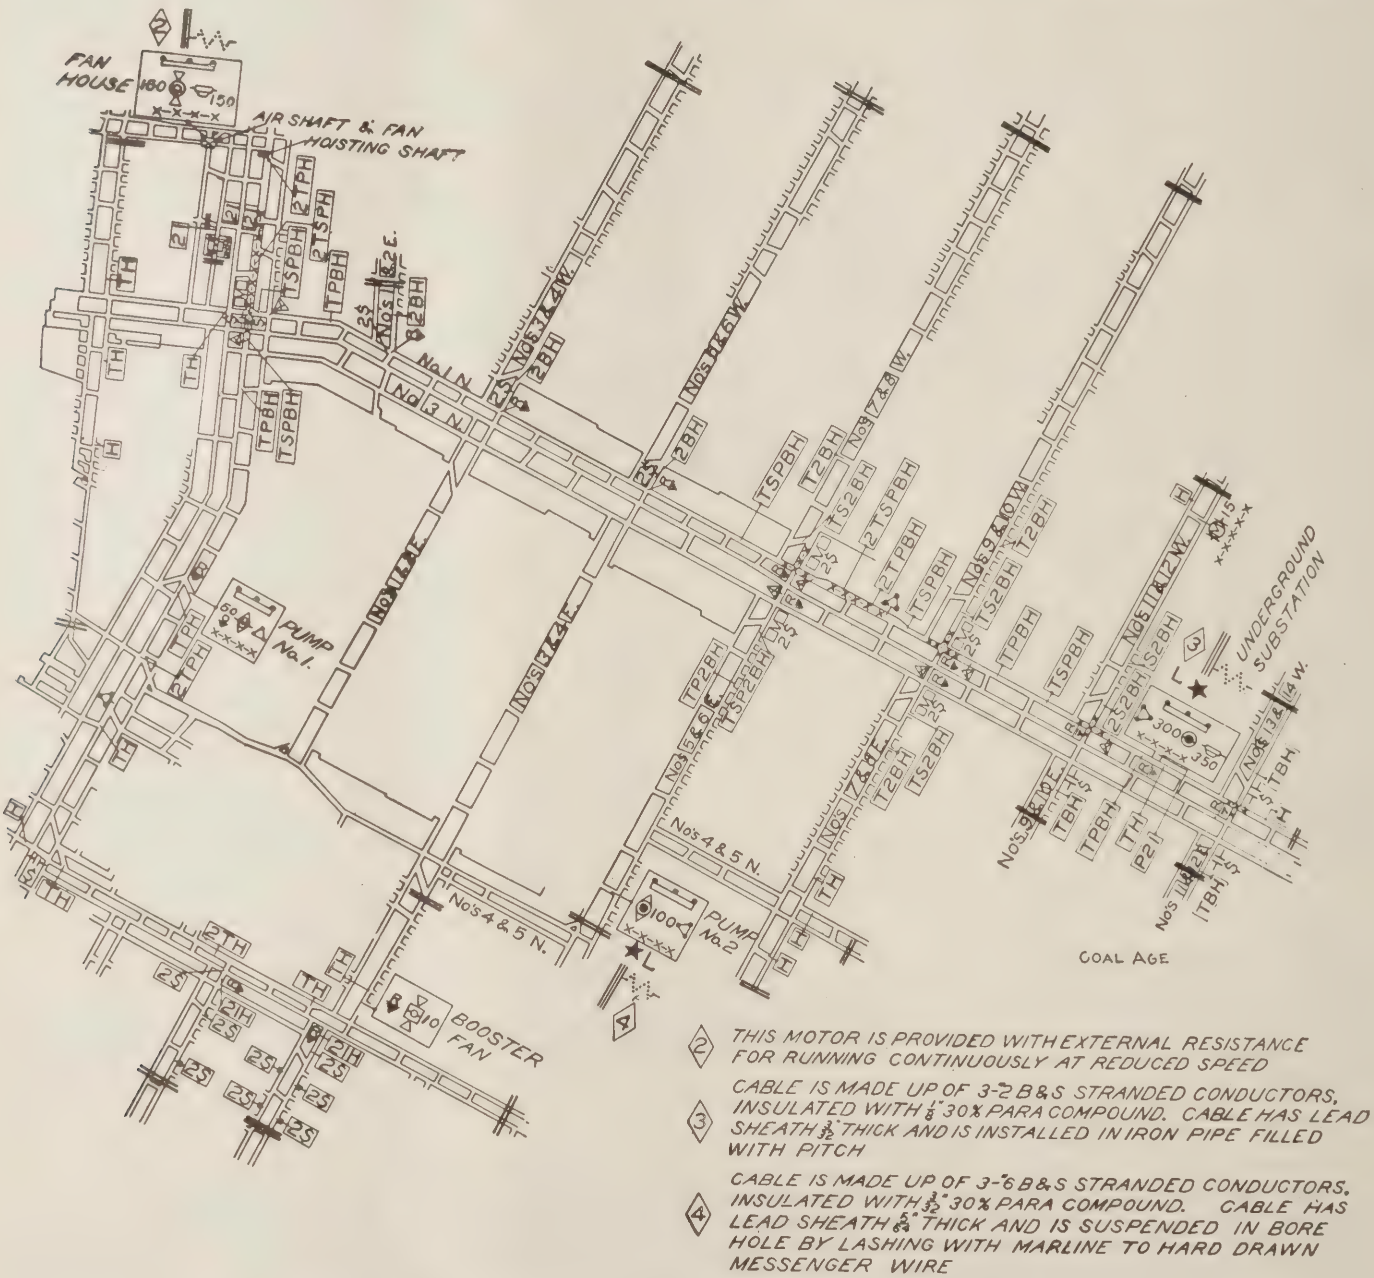

Fig. 4. Equipment with Alternating Current, Substations, Shot-firing Devices, Etc.

the pump room through the bore-hole and protected by a lightning arrester on the surface. Marginal note No. 4 gives some additional information in regard to the cable. The broken lines representing conductors have been omitted unintentionally from the drawing.

is supposed to use a system by which shots are fired from the surface and the shot-firing lines are carried to the face of all entries.

Starting from the hoisting shaft and working toward the inside of the mine, the symbols show that there are two

line is dropped. At the entrance to No. 4 West and No. 6 West the symbol "2BH" shows that two bare low-voltage conductors are installed in these entries. The next symbol on No. 1 North, which occurs between No. 6 and No. 7 West, indicates that the signal wire has been

picked up. At the entrance to No. 8 West a symbol shows that the trolley wire, a signal line, two bare conductors and a shot-firing line are carried up this entry. The next symbol shows where the signal line is dropped. The remainder of the conductors are carried up this heading. The failure to mark any further notes along the entry until the "stop" signal is reached outside the last crosscut, is evidence that the remaining conductors extend to that point without change. The next symbol on No. 1 North indicates the double trolley line at the parting, the signal line for No. 8 West and No. 6 East, a telephone line, a bare feeder, and a shot-firing line. The next symbol shows the dropping of the signal line. Following this there is a symbol which marks the end of the double trolley and the beginning of the signal line for No. 10 West and No. 8 East. Beyond this point in the following order TPBH marks the end of the signal wire, TSPBH indicates the beginning of another signal wire, which in turn is dropped at the next symbol TPBH. The symbol "TH" shows that both the telephone line and the bare feeder have been dropped. Just beyond No. 14 West the symbol "H" marks the end of the trolley while the shot-firing line is carried to the stop mark near the face.

Briceville Explosion

The following is the signed statement of J. F. Hatmaker.

I herewith make the following statement of facts:

"I was employed by the Knoxville Iron company as fire or gas boss, and the mines operated by them were classed 'B,' and therefore, did not require a fire boss at all. My business and instructions were to enter the mines at 6:30 p.m., after the day crew came out, to examine the ventilating apparatus and to see that it was in working condition. This I did. My duties then required me to proceed to examine the intake and return airways, to see that there were no obstructions. This I also proceeded to do and found everything O.K. I was also expected to visit such other places in the mine as in my judgment, might possibly be dangerous; which I did, as was required of me. On leaving the mine at 4:30 o'clock on the morning of the explosion, the mine in my judgment was in as good condition as it ever had been during the eight years I have been employed by the company as fire or gas boss.

Furthermore, I would refer to J. P. Woods, night foreman, who was with me in the mine that night and helped to make the inspection. Mr. Woods now holds a class 'A' certificate as mine foreman.

"I feel that some of the people of Briceville have done me an injustice, as they have caused me to leave my home, and have formed a mob to try to take my life, when I am as innocent, of the explosion, as any person on earth. I will be qualified that I had no idea that an explosion might occur because everything was in as good condition on the morning of the explosion as it ever had been, or at least those were the indications of my examining apparatus."

[Mr. Hatmaker's disavowal of responsibility will not meet with general approval. As appears in my report, the chief mine inspector required that "the mine be thoroughly inspected within three hours before each shift and before men enter the mine." This was possibly a physical impossibility for one man in such extended workings and perhaps it was not required of Mr. Hatmaker by his employers. But it would seem to be the intention of the state inspector that the inspection should cover every working place in the mine as though the fireboss had been appointed under that part of the law relating to class A mines. The men complain that the fireboss continually failed to register his visits at the face. —R. D. Hall.]

Release of Gas Accumulations

By W. H. Cunningham and C. R. Conner*

A seam of coal was worked and abandoned, the workings being allowed to fill with water. A seam above was opened by the same shaft. Later a huge column of water was thrown out of the shaft, followed by smoke and fire. Gas was removed at three points by boreholes from surface.

*Manager and assistant manager, West Kentucky Coal Co., Sturgis, Ky.

Note—Paper read before the December meeting of the Kentucky Mining Institute, Lexington, Ky.

From time to time we read or hear of some accident, due to the sudden release of accumulations of gas in abandoned mines or in the old workings of active collieries. This is usually caused by old workings being tapped unexpectedly by live workings.

There has been but little scientific research into the methods of relieving gas pockets and accumulations, and accordingly a broad field is left open for discussion; however, we will confine ourselves strictly to the method of handling one particular situation, which came under our direct supervision.

The Explosion

About 4:25 p.m. Saturday, Dec. 11, 1909, a huge column of water was thrown out of the main hoisting shaft, carrying with it the cage, which had been at the landing of No. 12 seam. The column of water was closely followed by smoke and fire, and almost instantly the tipple was enveloped in flames. As far as could be ascertained from eye witnesses, there were two explosions in rapid succession, which were heard a little after the flame was first seen shooting up the shaft, and these were later followed by some seven or eight minor explosions. As late as 8:30 in the evening two small explosions were heard.

Immediately after the explosion, relief parties were formed and hurried to the scene of the disaster; the state mine department was notified, as well as neighboring operators, who responded promptly, volunteering assistance, and by the time Assistant State Mine Inspector T. O. Long arrived at the mine (a little after 8 p.m.), the surface fire was under control, the shafts roped off and a force of men at work repairing the fan, which had been badly damaged. As soon as the fan was repaired, a rescue party was formed, which was joined the next day by Prof. C. J. Norwood, chief inspector of mines, who remained at the head of the relief party until the bodies of the seven unfortunates who lost their lives were removed from the mine.

History of Mines

The shaft had originally been sunk to the No. 9 seam, a distance of 211 ft., and after being worked for several years, the mine was abandoned, standing idle for some months, being allowed to fill up with water, the shaft also being filled to a point about 96 ft. from the top. It was then decided to make an opening in the No. 12 seam in the same shaft, a distance of 125 ft. above the No. 9 seam, and 86 ft. from the top of the shaft. This work was commenced before the writers' connection with this company. A map of the workings in the No. 9 seam, up to the time of abandonment, and a log of the hoisting shaft are shown, Figs. 1 and 2. At the time of the disaster, the opening in the No. 12 seam had been working nearly three years.

In the investigations held by the coroner's jury, county and state mining department, the coal company and its officials were held absolutely blameless. The state mining department then advised that before anyone would be permitted to reënter the No. 12 seam, it would be necessary, in some manner, to provide an outlet for future accumulations of gas in the No. 9 seam, to enable working in the upper seam with safety.

Drilling to Remove Gas

After thoroughly canvassing the situation, at a conference between Prof. Norwood, Mr. Long and the writers, it was decided that if boreholes could be drilled into the No. 9 seam, it would be the most practical means of relieving the situation and would meet with the approval of the state mining department.

The engineering problem which confronted us was not so much the drilling of the holes as the placing of them, so that they would tap points near the faces of the three rise headings in the lower No. 9 seam, and at the same time pass through solid pillars of coal in the upper or No. 12 seam. This was obviously deemed of the utmost importance in order to prevent possible leaks from the borehole casings into the No. 12 seam. The subject of escape of gases from wells into mines was ably presented by C. H. Tarleton, of the Consolidation Coal Co., of West Virginia, in his paper "Mine Explosives from Natural Gas Wells," read at the last annual meeting of the West Virginia Coal Mining Institute.

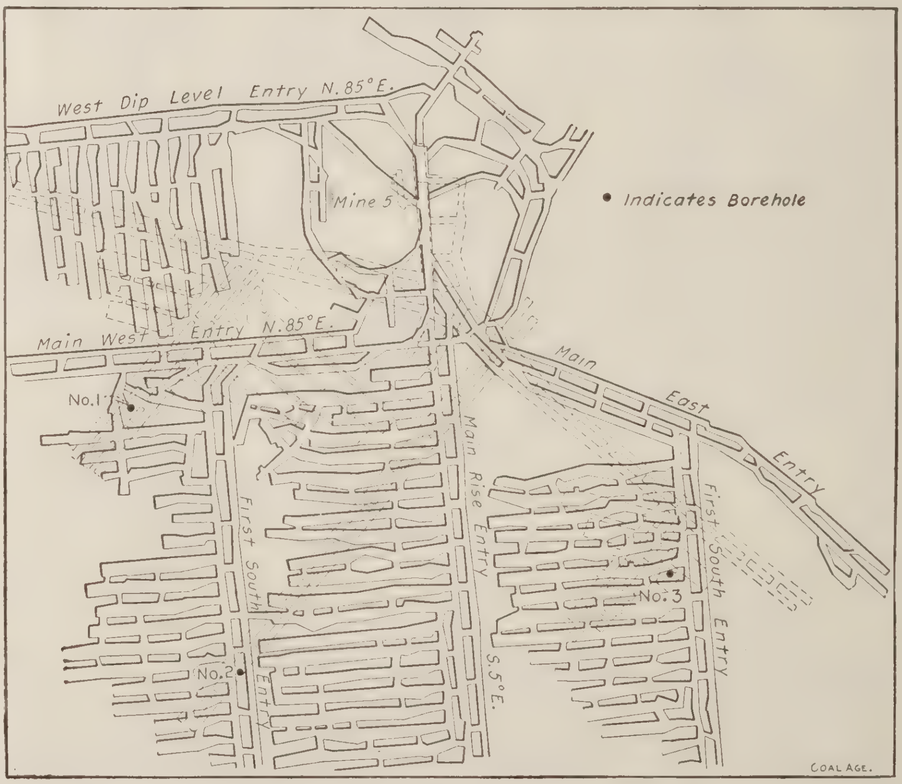

Fig. 1. Workings in Seams Nos. 9 and 12, and Location of Boreholes to Surface

Protection for Drill Holes

Old survey records of the No. 9 seam were carefully plotted, and, as far as possible, tied with and fitted to surveys in the No. 12 seam. The map, Fig. 1 accompanying this article, shows the nature of this work and the final location of the boreholes. We learned from old employees that the workings in the lower seam had been operated under considerable difficulties arising from the presence of firedamp, and we decided that when abandoned, it was quite probable that before a sufficient quantity of water had collected to fill all the workings, a considerable amount of gas probably accumulated at the faces of the three rise headings, being held in check by the pressure of the water standing in the shaft below the No. 12 seam. This was taken under careful consideration and caused the selection of the borehole locations as close as possible to the faces of the three rise headings in the lower seam, at the same time passing through good-sized pillars in the upper. The dip is 3.6 per cent. in a direction of N. 35° E., the three headings being driven directly to the raise.

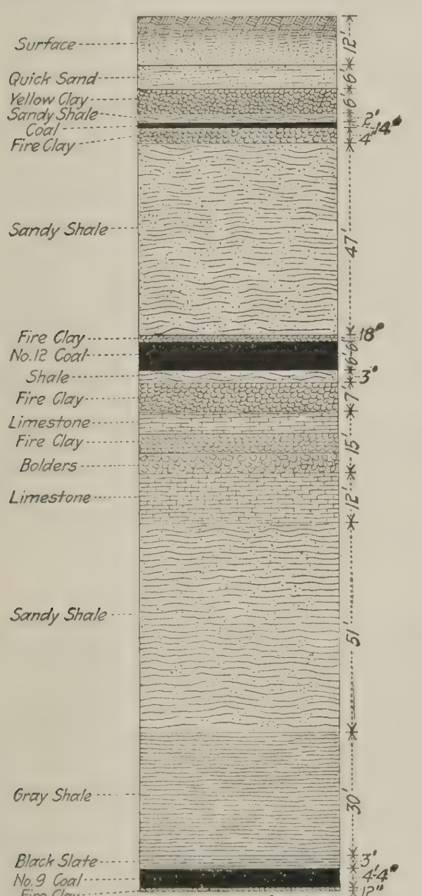

Fig. 2. Section of Coal Measures, Western Kentucky

On Dec. 18 work was started on the boreholes, using two ordinary churn-drill rigs. These put down holes to carry 8-in. casing to the rock, a distance ranging from 24 ft. in one hole to 80 ft. in the deepest. The bits were then changed, reducing the holes to a diameter suitable to carry 6-in. pipe. This was carried to a point 10 ft. below the No. 12 seam, then grouted with a mixture of one part cement to one part sand between the 6- and 2-in. casing up to the surface. The grout was allowed to stand 48 hours to set. From this point down to the No. 9 seam 5⅝-in. holes were drilled, in which 4-in. pipes were placed, the bottom 6 ft. of which were perforated in many places to permit the gas at the roof to escape while the ends rested on the bottom. From the surface down to a depth of 10 ft., grout was poured between the 4-in. and 6-in. pipe to prevent gas escaping anywhere except from the top of the pipes, which extended above the surface 20 ft. Upon the end of these three 4-in. pipes were securely fastened copper-gauze caps or hoods, 6 in. in diameter by 6 in. high, 784-mesh per sq.in., this mesh gauze being impervious to flame. The average cost per foot of these boreholes completed, including pipe, grouting and other material, was $2.75.

Further Precautions

When the holes were near completion, the fires under the drill-rig boilers were drawn and the holes completed by steam furnished from the boiler plant at the mine, this precaution being taken to protect the drillers. There was considerable pressure at the first hole for several hours after the drilling was completed, slight pressure at the third hole, and a noticeable suction down the second hole; however, an increased pressure was noticed at the first hole during the period of suction at the second hole. All three holes were successful in hitting the headings as planned.

At the completion of the drilling an inspection and test of the holes was made by Assistant State Mine Inspector Long, who also tested with a Lieler lamp around the pillars in the No. 12 seam, through which the holes passed. He found the work satisfactory.

As a further precaution, a 3-ft. concrete basin was built at the top of the shaft, into which is pumped all the water from the sump, which is the shaft below the No. 12 seam, the water being kept to a point 10 ft. below the cage landing. This enables a close watch to be kept on all water pumped out in order that any disturbance may be quickly detected. Since the mine has been in operation a watch is kept on the holes to see that they are in working order at all times, and we have found that they have well served their purpose.

Causes of Explosion

It may be of interest to members of this institute, for the purposes of discussion, to hear several of the theories advanced by mining experts as to the cause of the explosion. Several operators have advanced the idea that the explosion took place in the upper or No. 12 seam, a pocket of gas having been ignited by one of the seven men at work. The idea is further advanced that the rush of air after the explosion, in passing up the shaft, caused such a suction as to draw the column of water about 110 ft. deep up the 211-ft. shaft, releasing the pent-up gas from the No. 9 seam, the opinion being that the gas in passing up the shaft was fired at the opening to the No. 12 seam, setting fire to the shaft timbering and tipple.

A second theory was that air and gas were compressed in such volume that a heavy fall in the lower seam was sufficient to cause the column of water to be ejected from the shaft, followed by gas, which expanded through the upper seam and was ignited from the lamps of the men.

A third theory, and the one most generally accepted, is as follows: A large fall or some unusual disturbance in the No. 9 seam caused the ignition of the gas and subsequent explosion at that point, which forced out the water; the seven men in the No. 12 seam being overcome with afterdamp. From the position of the bodies when found, it appears that the men, who were the only ones in the mine at the time of the accident, were on their way to the shaft bottom, having finished work for the day. There was also little evidence of the explosion in the upper seam, and there were no lights at the cage landing, as the generator was not running that day; hence the third theory seems the most probable of those advanced, and particularly so from the fact that gas had never been found in the No. 12 seam in sufficient quantities to cause it to be mentioned in the reports of the mine inspector. This is also true since the mine has resumed operation.

It is impossible to obtain any exact information as to the origin of the explosion. The use of the boreholes has proved successful, permitting the uninterrupted operation of No. 12 seam.

In the discussion which followed, Prof. Norwood suggested that the expulsion of water was due to the natural pressure of the gas escaping from No. 9 seam. As the lights at No. 12 landing were electric, and as the generator was idle, the firedamp must have been ignited by the lamps of the miners. The doctor who attended the victims was of the opinion that the men died from the effects of steam. Mr. Cunningham explained that the pillars left around the boreholes in the upper seam were of 20-ft. radius.

Keep the electric motors and the damp spots separated if you would avoid trouble, for while they may both have their uses they make a bad combination when brought together.

Coal Mining Institute of America

Editorial Correspondence

Resume of discussion and and account of papers read at the Tuesday night and Wednesday sessions. So many papers were presented that the time for discussion was greatly restricted.

The opening session of the institute was largely recorded in the previous number. This session closed with two discussions, the first of which, "What kind of motor is safe?" developed more interest than available information, and is not elaborated on here.

Corrosive Action on Pumps

Discussion then followed on the question:

"What kind of pumping machine is best suited to withstand corrosive action?" Mr. Taylor said that the Bureau of Mines was testing the action of electric currents. He said remarkable results had been obtained relative to the immunity of materials from corrosion when protected by an electric current of the correct voltage. Mr. Affelder spoke favorably of wood and phosphor bronze, but Mr. Cameron, of Irwin, Penn., did not feel so well assured of its efficacy.

Mr. Hall explained the method of preventing corrosion by the use of a rubber composition dovetailed into valve seats. These seats could not be corroded in channels through the rubber composition: thus such channels could not be initiated and an important source of valve-seat destruction was thus removed. Mr. Taylor suggested that an electrolytic action might aid in the destructive work. Mr. Phillips said that wooden jackets in cylinders frequently buckled and caused trouble.

With the question box still unemptied, the meeting adjourned. Some communications of more than ordinary interest were of a private nature and were therefore stricken off the minutes, but these, with other arguments presented, were of considerable value and made the meeting of more than ordinary interest.

Evening Session of Dec. 19

The meeting was conjoint with that of the Engineers' Society of Western Pennsylvania, being numerously attended by members of that society. After a humorous address by Walther Riddle, president of the Engineers' Society, O. S. Lyford, Jr., of Westinghouse, Church, Kerr & Co., read a paper on "Power Plants with Special Reference to Requirements in Western Pennsylvania," which, as the author declared, neither applied to power plants generally, nor to western Pennsylvania specifically. The article related to turbo-generators of alternating current of large size scattered almost from coast to coast, and stated that the geographical location, while it might change the coal used, otherwise made no difference to the size and cost of the plant, for economy in the use of steam was to be advocated everywhere, as waste of steam involved larger boilers and turbo-generators with consequent equality in first cost.

The discussion was animated and well conducted, R. W. Stovel ably meeting all the criticisms advanced. The paper will receive much favorable consideration for it contained three tables of cost items in the installation of turbo-generator plants, which will be invaluable for reference.

Morning Session of Dec. 20

The morning session opened with a paper on "A Remarkable Coal Formation," by Jesse K. Johnston, of Charleroi. This referred to a thickening of what is generally regarded as the Upper Freeport coal, north of Pittsburg, extending from Hamarville south. The discussion seemed to indicate a doubt as to the identity of the bed, the opinion being advanced that it is an exceptionally clean bed to belong to the horizon in which Mr. Johnston and others would place it. The suggestion was made that the limestones by which that horizon was determined were unreliable and had long since been regarded as unsatisfactory keys to the identity of the measures in which they occur.

W. R. Crane read a paper on "Special Methods of Testing for Mine Gases," describing and demonstrating three European systems of determining the presence of noxious gases. An abstract of this paper will be found on another page. The paper by E. M. Weir, which followed, on "The Construction and Maintenance of Telephone, Signal and Trolley Lines in Mines," is also abstracted and appears in this issue. G. A. Burrell's paper, which created less interest than its merit demands, was printed in Coal Age last week. It is to be expected that the careful perusal of its interesting and original facts will make important changes in mining practice.

Wednesday Afternoon Session

E. N. Zern, assistant professor of coal mining, University of Pittsburg, read an article on "The Price of Coal Compared with Price of Materials Used in Mining." It was shown that the tonnage cost of coal was lower than that of most of the materials the operators must buy and which, it would seem, were not produced at any great expenditure of labor or capital. But in the absence of cost sheets of industries compared, the statement did not bring abounding conviction.

H. H. Clark's paper on "Electric Symbols for Use on Mine Maps to Indicate the Character and Location of Electrical Apparatus" is reprinted in full and it will be found of much value for reference. It is expected to figure largely in the discussion of appropriate signs by a committee which the chief of the mining department of Pennsylvania has called for that purpose.

Mr. Randolph's paper, which related to electric symbols in general, is not reproduced as such a subject is somewhat devoid of interest. However, it is understood that Mr. Randolph assisted Mr. Clark in the preparation of his symbolic dictionary and should receive full credit for his share in the meritorious work.

C. J. Griswold, assistant professor of mining, Carnegie Technical School, Pittsburg, gave a fluent and capable address on "Lignite Mining in Colorado," describing the difficulties arising from a shrinkage of 15 per cent. in the fuel between miner and consumer, the trouble between miner and operator, and the arrests by the city-scale tester. The fuel contains 23 per cent. of moisture, 8 per cent. of which evaporates within a week after mining. The roof is bad and a foot of lignite is left to support it. A pile of lignite slack 3 or 4 ft. deep will ignite spontaneously and the faces of pillars disintegrate to the depth of a foot. Royalties run about 25c. per ton, though a sliding royalty in proportion to tonnage per foot per acre worked is being put into operation.

Evening Session

The institute dinner followed at the Seventh Avenue Hotel. The flow of eloquence was clipped to the quick to permit of the address of President S. A. Taylor, who, with an excellently illustrated article on "The Coalfields of the World with Some Statistics and Data Thereon," occupied nearly the remainder of the evening. This lecture was, of course, delivered at the Engineers' Society rooms. R. D. Hall then exhibited some pictures of the Briceville explosion, accompanying them with a descriptive talk.

It was arranged that a query-box should be a feature of the summer session as it was of this winter meeting. The announcement of the subjects to be discussed is to be made a month before the institute convenes. No decision has been reached as to the place at which the next meeting shall hold session, but Johnstown has been suggested and is favorably regarded.

Pathogenic Mine Atmospheres—I

By Edwin M. Chance*

A consideration of the many methods of analyzing mine gases, with a discussion of their relative accuracy. The Fresenius-Winkler method is advocated for methane; the use of iodine pentoxide is favored for quantitative analysis of the monoxide.

The actual analysis of a sample of mine air is by no means as simple a matter as might at first appear. To begin with, the limit of error permissible in such work is of an entirely different order from that in the analysis of fuel or flue gases. The constituents to be determined, with the exception of oxygen and nitrogen, are for the most part present in extremely small quantities, while the presence or absence of one or two of these may be of vital importance. Thus the classic methods based on the selective absorption, in turn, of the various components of a gaseous mixture, the quantity of each being estimated by the decrease in volume of the gas, are unsatisfactory, except in the determination of oxygen. By this procedure such a small volume of sample is operated upon, and the substances to be determined are present in such small quantities, that the error is unpermissibly great. It is true that Haldane has devised a very ingenious apparatus working on the above principle. It has been the author's experience, however, that the apparatus is so complicated and its manipulation so cumbersome that other methods are preferable.

With these points in view, the writer has, after considerable experimentation, selected a number of methods from the literature of the subject, and has found them to give most satisfactory results. A detailed description of these methods would lie without the scope of this paper. It will suffice, therefore, briefly to touch upon their salient points.

Taking Samples of Gas

The gas samples are collected in copper cylinders of about 3 litres capacity, with conical ends, each end carrying an accurately ground tubulated brass stopcock. When a sample is to be taken, a cylinder is filled with clear water, and carried to the desired spot. On opening the cocks, the can will be filled with air as the water recedes. As soon as the can is free of water the cocks should be closed. If the sample is to be taken from a pipe or bore hole, a rubber tube of small bore, previously filled with water, is slipped over one of the cocks. The tube may then be thrust or lowered into the pipe or bore hole to the desired point. While holding the cylinder in a vertical position, with the cock bearing the rubber tube uppermost, the cocks are opened, when the desired sample will be drawn into the cylinder. It is important in using these cans to allow all water to drain out, when taking the sample, and to make the analysis as soon as practicable.

Carbon Dioxide Determination

Carbon dioxide is determined by the method of Pettenkofer or Hesse. This method has many variations. The following, however, has been found to give thorough satisfaction: A heavy litre or litre-and-a-half Erlenmeyer flask, the volume of which has been previously determined, is filled with water at room temperature, and then filled, by displacement, with the air to be analyzed. The flask is closed with a well-fitting two-hole rubber stopper, the apertures of which are closed by glass rods. A known excess of a clear solution containing 15 gm. of barium hydroxide and 1 gm. of barium chloride per litre is then run from an automatic pipette through one of the holes of the stopper. After closing, the flask is allowed to stand, with frequent shaking, for at least a half hour. At the end of this period the rods are withdrawn, the barium hydrate solution is tinted with phenolphthalein, and cautiously titrated with gas-normal oxalic acid. This solution contains 5.629 gm. of crystallized oxalic acid per litre, 1 c.c. being equivalent to 1 c.c. of carbon dioxide, measured at 0° C. and 760 mm. pressure.

While the carbon dioxide is being absorbed, another portion of the barium hydroxide solution is titrated with the oxalic acid. From this determination the ratio of oxalic acid to barium hydroxide is found. The volume of carbon dioxide in the sample operated upon is thus readily obtained by subtracting from the volume of oxalic acid, equivalent to the quality of barium hydroxide originally taken, the volume of oxalic acid required after the absorption of the carbon dioxide. In calculating the percentage of carbon dioxide, note must be made of the thermometer and barometer readings when the flask is filled with air for analysis.

From these values the volume of the air contained is reduced to normal conditions, first deducting the volume of the barium hydroxide added. Great care should be taken in adding the barium hydroxide, as well as in the subsequent titration, that there be as little opportunity as possible for the air in the flask to mix with the outside air. Most commercial samples of barium hydroxide contain some alkali metal hydroxide. In such a case alkali metal oxalate may be formed, when at the close of the titration the following reaction will occur:

$$Na_2C_2O_4 + BaCO_3 = BaC_2O_4 + Na_2CO_3$$

Under these conditions the bleaching of the color of the phenolphthalein is not permanent, the color returning after repeated addition of acid, and thus shrouding the end point in uncertainty. By the addition of barium chloride the alkali metal hydroxide is converted to chloride and rendered innocuous, the end point once more becoming sharp. As the dilute solution of oxalic acid used is far from stable, a fresh solution should be frequently prepared. The barium hydroxide solution should be protected from the carbon dioxide of the air by the usual methods.

The accuracy of this method has been demonstrated by the exhaustive researches of Letts and Blake. Its precision will become apparent when it is considered that, granting the burette may be read to 0.05 c.c. and that 1000 c.c. of air are operated upon, the error in reading should not exceed 0.005 per cent. of carbon dioxide. There is, of course, an ever-present error due to the solution of carbon dioxide in the water when filling the sample can and transferring the air to the flask. This error, however, is small with careful work. Hydrogen sulphide and sulphur dioxide, if present, must be corrected for.

Methane Determination

The determination of methane is best carried out on the residual gas from the carbon dioxide determination, although, if desired, a fresh portion may be taken. Two methods recommend themselves for this purpose. In the first, or Winkler's method, the methane is slowly oxidized by means of a heated platinum helix and atmospheric oxygen. In the second it is oxidized by contact with heated copper oxide, independent of atmospheric oxygen.

If the first method is to be pursued, the original copper is replaced by one carrying two brass rods, the transfer being made while the flask is held inverted with its mouth just under water. These rods extend within about 5 cm. of the bottom of the flask, and are joined at their inner extremities by a piece of platinum wire 0.35 mm. in diameter and 7 cm. long, bent in the form of a helix. The outer extremities are connected with a source of electricity. The flask is inverted and held in this position entirely submerged in a bath of cold water. A current of electricity is now passed through the ap-

*Chief chemist, Philadelphia & Reading Coal & Iron Co., Pottsville, Penn.

Note—Abstracted reprint from Journal of Franklin Institute, November, 1911.

paratus sufficient to raise the platinum wire to a dull red heat. It is gradually increased during a half hour to about 9 amperes, or sufficient to bring the platinum to incipient whiteness.

At the expiration of this period the current is broken, the flask removed from the water, the stopper used in the carbon dioxide method substituted for the one bearing the brass rods, and the carbon dioxide formed by the combustion of the methane is determined as previously described. In this case, however, each c.c. of oxalic acid consumed is equivalent to 1 c.c. of methane, measured under normal conditions.

This method has many drawbacks. Heat enough is often generated to develop pressure sufficient to cause leakage of gas around the stopper, to blow the stopper out or to burst the flask. The flask may be subjected to such unequal heating as to cause it to crack spontaneously. It is always possible that traces of methane may escape oxidation. Moreover, if the percentage of methane be high, as in the analysis of fire damp, or if the percentage of oxygen be low, as in the analysis of black damp, it is necessary to mix the gas to be analyzed with either pure air or oxygen, an operation which is time-consuming, troublesome, and apt to engender grave errors. Should the percentage of methane fall within explosive limits, the method is entirely inapplicable, as even with dilution there is danger of an explosion. Under ideal conditions the accuracy obtainable by this method is of the same order as that in the carbon dioxide determination.

Another Method

After a lengthy trial of the first method, the writer has adopted the second, or that of Fresenius modified by Winkler. Either the flask containing the air from the carbon dioxide determination, or one filled with a fresh sample, is arranged so that the contained gas may be displaced by water. The air is led first through a soda lime tube, a calcium chloride tube, and then a combustion tube. This combustion tube is of heavy copper, 45 cm. long and 2 cm. in diameter. It is partly filled with coarse copper oxide, is heated to redness by four Bunsen burners, and is provided, at either end, with an annular copper jacket, about 5 cm. long, through which cold water is circulated. These water jackets cool the perforated rubber stoppers through which the air is led, as well as the copper gauze with which each end of the tube is packed. This gauze serves a double purpose; it holds the copper oxide in place, and, should the gas to be analyzed be explosive, acts as the gauze in a Davy safety lamp, eliminating danger from this source.

The air, on leaving the combustion tube, is passed through two 200-c.c. Erlenmeyer flasks. These flasks contain a known volume of barium hydroxide solution, of the same strength as used in the determination of carbon dioxide, and a few drops of phenolphthalein. After the sample of air has passed through the combustion train, an operation requiring about 35 minutes, the flask in which it was originally contained is removed, and air from without the building is aspirated through the apparatus for about 25 minutes. The two absorption flasks are removed, their contents combined and titrated with oxalic acid as in the determination of carbon dioxide.

This method will give accurate results irrespective of the proportion of oxygen or methane in the original sample. The copper oxide in the tube is regenerated by the passage of air after the gas sample, thus leaving the tube in good condition for the next determination. It is important that the air samples should not be passed through the apparatus too rapidly, and that a notable excess of barium hydroxide be maintained in the absorption flask. The barium hydroxide is therefore tinted with phenolphthalein to give warning of its depletion.

It might be well to review some considerations governing these methods. In correcting the volume of the sample in the flask, if the residual air from the carbon dioxide determination be used, both the volume of barium hydroxide and oxalic acid used in the carbon dioxide determination must be deducted before reducing the air volume to normal conditions. In the first method, when calculating the volume of air in the flask an additional deduction must be made for barium hydroxide added and for the volume of the brass rod electrodes. Of course, in the second method this correction does not apply.

In determining methane by the first method, on a sample of air from which carbon dioxide has not been removed, the percentage of carbon dioxide in the air must be deducted from the percentage of methane found. This correction is unnecessary in the second method, as all carbon dioxide is removed by the soda lime tube. In both methods the percentage of carbon monoxide in the air must be deducted from the percentage of methane found, as one volume of carbon monoxide burns to one volume of carbon dioxide as does one volume of methane. In the first method hydrogen sulphide and sulphur dioxide, if present, must also be corrected for.

Carbon Monoxide Determination

The accurate determination of even traces of carbon monoxide is of paramount importance. This fact, coupled with the chemical properties of the gas itself, renders recourse to special methods necessary. The well-known unreliability of the methods based on its absorption by solutions containing cuprous chloride forbids even the thought of their application here.

Haldane has endeavored to apply the well known gas volumetric method based upon the changes of volume occurring when this gas is burned and when the resultant carbon dioxide is absorbed. As has been noted, however, such methods, through inherent weakness, would seem to fall short of giving the desired accuracy. There is, moreover, nothing positive about these methods.

Blood-test Disparaged

For this reason the so called blood-test has found considerable favor. In this test advantage is taken of the pink color given to dilute solutions of blood by carbon monoxide hemoglobin. This test, when properly performed by an experienced operator, gives qualitative indications of undoubted value. The personal equation, however, plays too prominent a rôle to permit of its quantitative application, though much has been written to the contrary. If the blood solution containing carbon monoxide be examined spectroscopically the indications are said to become quantitative, however, this method having a wide application in the field of forensic chemistry. Apropos of the qualitative value of the blood-test, another well known qualitative test might be mentioned.

This consists in passing the air to be examined through a solution of sodium cuprous chloride, diluting somewhat and adding a few drops of sodium palladious chloride, when, if carbon monoxide be present, a black precipitate should be formed. This test may be varied by passing the air through a small quantity of water containing strips of filter paper moistened with palladious chloride, the paper blackening in the presence of this gas. A quantitative variation based upon these reactions has been brought forward by Potain and Drouin. The detection of carbon monoxide by any of these alternatives is, however, unsatisfactory, as too great a volume of air is required for convenience, and there are many interfering substances.

A method has been devised by Spitta, in which the carbon dioxide produced by the combustion of carbon monoxide by silver electrodes, coated with palladium and heated to 150° to 160° C., is determined by Pettenkofer's method. This method is said to be applicable in presence of hydrocarbons, and to possess considerable accuracy.

Preferred Test

Probably the methods best adapted to the determination of carbon monoxide in mine air are based upon its oxidation by iodine pentoxide, as pointed out by de la Harte and Reverdine. This reaction proceeds as follows: $5CO + I_2O_5 = 5CO_2 + I_2$, and is quantitative at from 150° to 160° C. If this latter temperature be not exceeded, methane and hydrogen have no

action on the reagent, though hydrocarbons of the ethylene and acetylene series are attacked. As the latter gases occur but rarely in appreciable proportions in mine atmospheres, their action may generally be neglected. Hydrogen sulphide and sulphur dioxide might also interfere, but may be readily removed.

Many different applications of this method have been brought forward. Gautier absorbs the carbon dioxide formed, and measures its volume after liberation by acid. The same author bases a gravimetric method upon the absorption of the iodine by spongy copper. Nicloux, working at the same time as Gautier, though independent of him, has published a procedure in which the amount of iodine evolved is determined colorimetrically after its solution in chloroform. Fillinger has described an apparatus brought forward by Molterski and Norwicki, in which, after removal of the free iodine by metallic silver, the carbon dioxide generated is determined by Pettenkofer's method.

Other Modifications

Their procedure, with slight modifications by the author, may be thus described: One of the copper sample cans containing the air to be analyzed is placed in a vertical position, and so arranged that water, at room temperature, may be admitted through the bottom tap. The air thus displaced passes through the upper tap to a U tube, the first leg of which contains calcium chloride, the other soda lime. It then passes through a small U tube, containing about 25 gm. of iodine pentoxide, mixed with sufficient glass wool or asbestos to render it porous. From this tube the air passes to a Bowen absorption tube containing about 5 c.c. of 10 per cent. potassium iodide. The tube containing the iodine pentoxide is surrounded by a sand bath, the temperature of which is held between 150° and 160° C. The sample of mine air is passed through the apparatus at a rate of about 1 litre per hour. One litre of air is the quantity usually used, though more may be taken if desired.

After the requisite quantity of air has been passed through the apparatus the lower cock of the sample can is closed, and when the bubbles cease to pass through the absorption tube the upper cock is closed and the can is removed. An aspirator is attached to the absorption tube and a slow current of air from outside the building is drawn through the apparatus for about one-half hour. The absorption tube is then removed, its contents rinsed out with distilled water, and titrated with N/1000 sodium thiosulphate, with the addition of a little starch liquor. Each cubic centimeter of thiosulphate is equivalent to 0.056 c.c. of carbon monoxide, measured under normal conditions. The quality of air which has been passed through the apparatus may be determined by measuring the quantity of water in the sample can, or by noting the increase in weight of the can. The volume of air thus determined must be reduced to normal conditions.

Kinnicutt and Sanford Method

In their paper, Kinnicutt and Sanford recommend the purification of the air before bringing it into contact with the iodine pentoxide, by passing it first through concentrated sulphuric acid and then over solid potassium hydroxide. This procedure is said to eliminate interfering unsaturated hydrocarbons. As the presence of such in mine air is problematic, as the sulphuric acid, owing to its contamination by organic matter, is apt to generate sulphur dioxide, and as the back pressure of the column of acid would have to be allowed for in computing the volume of air used in analysis, the simpler combination described has been substituted, the function of which is to remove hydrogen sulphide, sulphur dioxide, and water vapor. Should the presence of ethylenes or acetylenes be suspected, the former method may be desirable. These writers, in their work, used an oil bath.

It has been found, however, that such baths are not applicable here, as the oil creeps and on coming in contact with the iodine pentoxide liberates iodine. It is important to keep the volume of the purifying tube as small as possible, as less air is thus required to sweep the apparatus clean. It is not practicable to use the air of the laboratory for this sweeping out, as it generally contains sufficient carbon monoxide from leakage of illuminating gas to vitiate the results. The apparatus throughout should be glass-stoppered, and all connections should be of glass tubing, held firmly with glass against glass, so that there is as little contact as possible with rubber. The weak standard sodium thiosulphate is far from stable. For this reason it is best to prepare a N/10 solution and to dilute 10 c.c. of this to 1 litre as required.

Oxygen Determination

Of the many methods proposed for the estimation of oxygen, two have stood the test of long usage. In the first the oxygen is absorbed by a solution of pyrogallol in strong potassium hydroxide. In the second the slow combustion of phosphorus at room temperature is utilized. While these methods are so well known that their description is unnecessary, a few remarks concerning the applicability of each might be acceptable. The pyrogallate method gives results of unquestionable accuracy when properly carried out. The solution, however, due to its causticity, is unpleasant to handle. It, moreover, deteriorates rapidly, and there is therefore some uncertainty as to the efficiency of a previously-used solution. The advantage of the method lies in the fact that other gases do not interfere with the absorption of oxygen.

In the phosphorus method the pipette containing the reagent must have a temperature of at least 18° or 20° C., the absorption being very slow below this point, almost ceasing, indeed, at 7°. In the presence of certain gases the action of the phosphorus is prevented. Brunck states that the absorption is not rendered slower or less complete by the disturbing gases, but that if white fumes are evolved on bringing the air to be analyzed in contact with phosphorus the reaction will be quantitative. The writer has not met with a sample of mine air to which the phosphorus method was inapplicable. Should difficulties be encountered, however, the former method will be found satisfactory. The advantages of the latter method are its cleanliness, rapidity, and accuracy. An apparatus when once set up can be used for years without renewal of the reagent. The Lindemann-Winkler apparatus will be found convenient, as it is self-contained, requires little manipulation, and may be carried into the mine when desired.

Determination of Other Gases

Nitrogen is always determined by difference.

Hydrogen sulphide and sulphur dioxide are generally detected by their odor. It is better, however, in the case of hydrogen sulphide to use strips of alkaline lead acetate paper, as the olfactory organs are apt to become untrustworthy. Quantitatively it may be determined by the depth of color produced when a known volume of air is passed over lead acetate paper, or by passing the air through a solution of iodine and volumetrically determining the iodine consumed by black titration with sodium thiosulphate. Sulphur dioxide may be determined iodimetrically as just mentioned, or may be weighed as barium sulphate after oxidation with hydrogen peroxide.

The results of an analysis of mine air for ready interpretation are stated in two forms. The values found for oxygen, nitrogen, carbon dioxide, carbon monoxide, and methane comprise the first. The percentage of normal air is then calculated by multiplying the percentage of oxygen found by 100, dividing by 20.93. This value is termed "air." Methane is reported as "fire damp" and carbon monoxide as "white damp." The percentage of carbon dioxide less 0.03 per cent. is termed "excess carbon dioxide." One hundred per cent. less the sum of the percentage of "air," "excess carbon dioxide," carbon monoxide, and methane gives the "excess nitrogen." It is often convenient to term the combined values for "excess carbon dioxide" and "excess nitrogen"—"black damp." The second statement of results will therefore contain the figures for "air," "fire damp," "white damp," and "black damp."

Methods of Testing for Mine Gases

By W. R. Crane*

Recently devised methods of testing mine air for the gases it may contain are becoming more complicated and difficult. Description of a new marsh-gas detector. A suggestion of a mine signaling system to warn the officials of accumulations of gas in the mine.

The gases found in coal mines are not so many or varied in character as to lead to confusion in the methods of testing; although, as time goes on, the methods of testing for the various gases are becoming more varied and in many cases more complicated and difficult for the ordinary individual to understand. Many of the appliances and methods for detecting the presence and quantity of gases in mines are based upon well but not widely known chemical and physical laws. Their use, therefore, by the ordinary mine official, must of necessity be according to rule of thumb, rather than from any exact knowledge of the theory upon which the apparatus is based.

The three most common, and therefore, most important gases found in coal mines are marsh gas, carbon dioxide and carbon monoxide. Nitrogen will not be considered here as a mine gas since it is a constituent of air. It forms, however, a part of all firedamp and blackdamp. . . . Nitrogen is, therefore, always present in the gases resulting from the combustion of marsh gas and air. While it is not impossible to determine the presence and the amount of firedamp present in a given mine atmosphere, yet it is not readily done and consequently, unless great care is taken, the results obtained may be quite inaccurate. Furthermore, as the same result may be arrived at by numerous simple and accurate ways, it seems undesirable to employ round-a-bout means to secure possibly less accurate results. The essential thing that we wish to know is what per cent. of marsh gas is present; then knowing the percentage of gas that is well within the limits of safety, we have all the information that is necessary. Firedamp is composed of any mixture of marsh gas and air ranging between the limits of 1 volume of gas to 3½ volumes of air and 1 volume of gas and 30 volumes of air, which gives the full range of combustible mixtures of this gas and air, and shows the term firedamp is really an uncertain expression.

Carbon monoxide, though not a constituent of mine air, is often found in coal mines, in dangerous quantities. Its presence in the mine air is due to the burning of explosives or other forms of incomplete combustion. It is particularly noticeable immediately after firing a shot at the face, where it can usually be detected by a candle or safety lamp.

A Marsh Gas Detector

The safety lamp is, of course, the standard method of testing for marsh gas and its use is so well known that it will not be considered in this connection. The following method of testing for marsh gas has recently come to our attention and owing to its simplicity and accuracy it is deemed worthy of brief mention.

The action of this detector or testing device is based upon the fact that certain metals will absorb gases either on their surface or in their mass, which property is designated as *occlusion*. Platinum and palladium will absorb large quantities of hydrogen, particularly when heated to a certain temperature. Platinum will absorb four times its volume of hydrogen; iron wire 0.44 its volume of hydrogen; silver once its volume; while palladium will absorb 980 times its volume of hydrogen. Platinum occludes other gases besides hydrogen; particularly oxygen, of which 250 times the volume of sponge platinum is absorbed. While no definite figures are available as to the capacity of wire or sheet platinum to absorb oxygen, yet it is probably safe to say that fully 100 volumes of oxygen are absorbed by platinum in the solid state. . . . The apparatus consists of two pairs of strips of dissimilar metals *A* and *B*, Fig. 1, fastened rigidly to blocks at the end of each pair, the free ends of the pairs extending toward each other and slightly overlapping. The dissimilar metals are so arranged that when heated unequal expansion of the members of the pairs causes a downward-bending or deflection of the pairs. Directly below the respective pairs and in close proximity with them are placed coils of wire *C* and *D*, through which an electric current is maintained, as constant as possible, although that is not absolutely necessary to the proper and accurate manipulation of the apparatus.

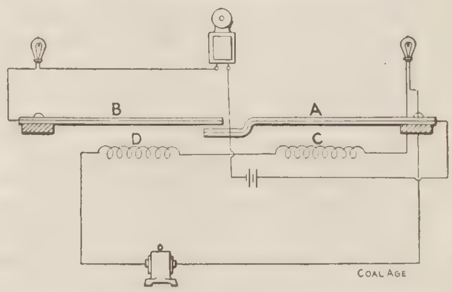

Diagram of Marsh Gas Detector for Use in Mines.

One of the coils *C* is made of ordinary resistance wire, the other *D* being platinum. A current sent through these two coils will generate, when hydrogen or compounds of hydrogen are not present, an equal amount of heat, thus causing the two pairs of strips to be deflected to the same extent. In the presence of hydrogen the conditions are quite different. The platinum absorbs the hydrogen and when the proper temperature has been reached combustion will take place between the hydrogen thus collected and the oxygen of the air. The temperature at which ignition takes place is somewhat above 500 degrees Fahrenheit.

When the hydrogen in the atmosphere is not in the free state but is combined with carbon, forming marsh gas or in fact any of the hydrocarbon series, a catalytic action takes place about the platinum and the marsh gas is probably decomposed, setting free both hydrogen and carbon, which then combine with the large quantity of oxygen present. Considerable heat is thus generated and materially increases the temperature of the platinum coil *D* above that of the resistance coil *C*. The pair of strips *B* is thus subjected to the greater heat or higher temperature and will naturally be deflected more, the result being that the two overlapping ends of the pairs will come together, thus making connection and so completing the circuit of a bell or incandescent light or both as desired.

As indicated above it is not necessary to employ a current of constant voltage, neither is it necessary to concern ourselves about the external temperature and its changes, as the apparatus is responsive to the effects of marsh gas only, which is in this case the element of danger.

Adjusting the expansion-pairs by bringing them closer together or moving them further apart, renders it possible to make the apparatus exceedingly sensitive to the presence of hydrogen. The apparatus may then be tuned as it were to suit the desires or requirements of those in charge of a mine, or if it so happens, meeting the demand of the law governing and regulating the amount of gas allowed in a mine.

The signal, be it a bell or light, will continue to respond to the presence of the danger element until it has been removed or a switch has been thrown cutting out the signal.

Another decided advantage aside from

*Professor of mining engineering, Penn. State College, State College, Penn.

Note—Abstract of paper read before the Coal Mining Institute of America, Dec. 20, 1911.

the sensitiveness of the apparatus, consists in the fact that the presence of gas can be indicated at practically any distance from the point of its accumulation in the mine. Further, any number of indicators may be placed at various points in a mine, all being connected by a system of wiring to a central underground station, or office on the surface. By this means it would be possible for the official in charge to keep himself informed as to the condition of the mine, and by a slight additional expense, recording instruments could make permanent records of the condition of the mine atmosphere.

[Dr. Crane's paper further described a form of apparatus known as the Simonis carbon monoxide detector, which, he stated, was considerably more complicated in its construction and operation than the usual blood test employed to detect the presence of that gas. The paper also described Dr. Haldane's proposed method of detecting the presence of blackdamp in mine air, which formed the subject of a paper read two weeks previous, by Dr. Crane, before the West Virginia Mining Institute meeting, held at Fairmont, W. Va. This paper was published on page 281 of COAL AGE, Dec. 9, 1911.—EDITOR.]

The Maxwell Colliery

The collieries of the Pennsylvania anthracite field may in general be said to range in daily capacity from 1000 to 4000 tons of prepared coal. With an output of 3000 tons per day, the Maxwell colliery at Ashley, Penn., ranks as one of the larger operations of the Wyoming region. A photograph of the Maxwell breaker and surroundings is given on the front cover of this issue, and is presented because of its excellent portrayal of a typical anthracite plant rather than with an idea of depicting any particular phase of colliery construction or practice.

Ashley lies several miles to the south of Wilkes-Barre, Penn., and nearly at the southern extremity of the Northern anthracite field. At this point the coal measures begin to bear evidence of the violent disturbance which has resulted in the steeply pitching veins of the Middle and Southern fields; and both flat and pitching seams are mined at the Maxwell colliery. Two shafts, to the Baltimore and Red Ash veins, respectively, and a slope to the Hillman vein, bring to the surface the coal from the six seams which are worked on this property.

The breaker shown in the photograph was erected in 1895 and remodeled in 1907. In a field where the slightly varying conditions at different operations are met by distinctly different forms of construction and methods of operation at the individual plants, it is frequently difficult to distinguish between old and new practice, but it may be said of the Maxwell breaker that the tower hoist marks it at once as belonging to an older type of construction. The slanting back brace of the tower for this hoist is easily distinguishable in the photograph, as is also the front end of the engine house. The function of the hoist is to lift mine cars from the ground level to the head of the breaker; and in nearly every instance of more recent construction this arrangement has been superseded by an inclined conveyor or by a car plane.

The dry method of coal preparation is employed at the Maxwell breaker, that is to say, the coal, excepting the buckwheat sizes, is not subjected to a washing or jigging process, but is cleaned by various mechanical devices insofar as practicable. As previously stated, the colliery produces 3000 tons daily.

This property is owned and operated by the Lehigh & Wilkes-Barre Coal Co., Wilkes-Barre, Penn.

Telephone, Signal and Power Lines for Mines

BY E. M. WIER*

A great deal is heard at present in regard to standard equipment and scientific management for industrial concerns. Among railroads, manufacturing companies and other industries, these subjects are receiving, with beneficial results, the attention of those who direct the enterprises. I have had occasion to visit a large number of mines in different parts of the United States, Canada and Europe, and the one thing that has most impressed me in regard to them is the lack of standard methods for the installation of telephone, signal and power lines, and the lack of standardization of electrical apparatus in general.

This condition of electrical mining equipment is in strong contrast to the present-day practice of other large industries. At first, in all industrial lines standard specifications for electrical equipment were practically unknown, and as many different methods of installation and varieties of apparatus were used as there were companies employing electric power. But since this period of pioneer work, order has been brought out of chaos, and today we have standardized electrical equipment for practically every line of work except that of coal mining.

Lack of standardization involves greatly increased expense. The burden of this expense is borne, first, by the coal operator, and then to some extent by the manufacturer and jobber of supplies. The two latter are required to carry a stock of many different kinds of apparatus and material, and must charge enough for their supplies to offset the investment of a large amount of money in the surplus stock, whereas, if installation and equipment were standard, the amount of extra and special material which need be made and kept on hand, would be greatly reduced with a consequent reduction in the price of the individual articles.

As I see it, the benefits to be gained by standardization in the coal-mining industry of electrical apparatus and methods of installation and transmission, may be summarized as follows:

(1) The supplies could be purchased more cheaply, because they would be manufactured in larger quantities, and because the expense of selling them would be reduced.

(2) The investment for equipment would be less, because the apparatus would be designed along scientific and efficient lines, and because its installation by labor trained in the use of standard methods would be cheaper than it is under present haphazard conditions.

(3) Profits of the industry would be increased because there would be less trouble developed in the various installations; there would be less delay in making repairs and securing repair parts; and because the mine superintendent would know just what to order instead of having to guess at it as at present, and, incidentally, would have more time to devote to other matters.

Note—Abstract of paper presented before a meeting of the Coal Mining Institute of America, Pittsburg, Penn., Dec. 20, 1911.

An Endurance Test of Roller Bearings for Mine Car Wheels

The widespread interest which has developed during the last few years in respect to the economies effected by the use of roller bearings of one type or another in mine-car wheels, has resulted in many manufacturers placing on the market a line of wheels of this type and in their making accurate tests to demonstrate the practicability of this form of bearing for mine-car service. It is, of course, conceded that roller-bearing wheels effect great power economies, but many have had doubts as to whether or not they would stand up for any length of time under the severe conditions of mine work.

The following test, which was conducted by one of the largest manufacturers of mine cars in the country, was undertaken in order to ascertain which of two forms of roller bearings would stand the hardest service, or, it might be said, the greatest amount of abuse the flexible steel spiral roller or the solid cylindrical steel roller type. A roller bearing of each of these two types was fitted in journal boxes on a 2½-in. lineshaft. One of these bearings was of the Hyatt spiral steel-roller type, 6 in. long and operating in a box similar to that shown in Fig. 1. The other was a solid steel-roller bearing mounted in a similar box.

Device for Making the Test

Between these bearings was placed a babbitted journal box 7 in. long; and on the ends of the shaft, just outside of each of the roller bearings, were placed two more journal boxes of the same type, making three babbitted journals carrying the same load as the two roller bearings. Across the tops of these two roller-bearing boxes were placed heavy I-beam levers, one end of each attached to the floor and the other end carrying a 400-lb. cast-iron weight. The weight thus brought upon each of the roller bearings was 2720 lb., which made the load sustained by each plain bearing about 1800 lb. The shaft was then rotated at a speed of 185 r.p.m., equal to nearly 10 miles per hour with 18-in. diam. car wheels. The arrangement of bearings, levers and weights is shown in Fig. 2.

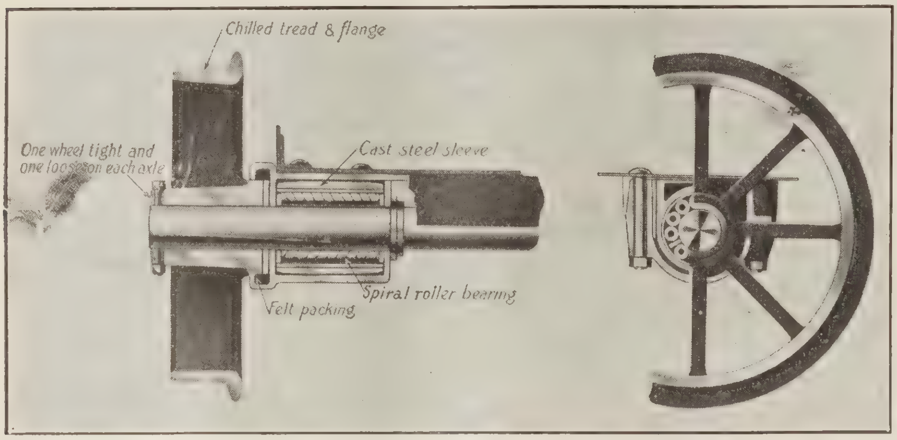

Fig. 1. Spiral Roller Bearing Applied to a Mine Car

At the end of two hours' run, or about 20 miles under this load and speed, the 7-in. babbitted bearings melted out, although a man stood by and oiled then. almost continually. They were then replaced by 2½x7-in. brass car journals. At the end of 6 hours' further run the spacing rings on the solid roller bearing had cut ridges in the rollers. The spiral roller bearings up to this time were absolutely uninjured. At the end of 17½ hours' run another examination was made, with no further developments.

At the end of 38 hours' additional run the rollers in the solid-roller box showed minute pock-marks on their surface, the metal in the rollers seeming to fall out in small granulations. At the end of 57 hours' additional run the linings of the solid-roller bearings likewise commenced to granulate and roughen.

Test Equivalent to a Year of Service

All were then allowed to run 152 hours more without further examination. At the end of this time the solid rollers were bent, the axle cut and ringed by the ends of the rollers and its diameter reduced 1/32 in. The linings of the solid-roller boxes were granulated. In the spiral-roller box the rollers were still in perfect condition. The bearings were then run 204 hours longer, making a total of 476 hours, which would be equivalent to nearly 5000 miles of car travel, or to at least a year's service in a mine. The spiral-roller bearing at the end of that time appeared to be undamaged, although it was apparent that the solid-roller bearing would last but a short while longer.

The trial was then resumed and run for 8½ hours. Before starting, the oil in the box was mixed with fine coal dust and a double handful of coal dust was poured on the rollers. The rollers in the Hyatt bearing ground this dust to powder, mixed it with the oil and took it up in their spiral hollows, no damage being done to the bearings. The solid-roller bearing ejected the coal dust from the box without further damage to the bearing, but thereafter it ran much harder. The brass car bearings became so hot that the oil in these journals reached the boiling point.

Fig. 2. Testing Device Showing Method of Applying Load

The speed was then increased to 380 r.p.m., which is equivalent to nearly 20½ miles per hour, and the weight was reduced to 1200 lb. At this speed and weight the brass car bearings could not be kept cool enough to run. They heated, cut and practically ruined the shaft. No damage, however, was done to the roller bearings.

At frequent intervals during this test the bearings were sledged on top with 16-lb. sledges, to give as nearly as possible the effect produced by violently striking the horns of a tipple dump. The load was also jostled up and down and sideways, after the fashion of the load in a mine car running at a high rate of speed. None of these measures, however, seemed to do any damage to the Hyatt bearing. It would be difficult to say just what part of the total wear of the solid-roller bearing may have been due to these latter variations of the test.

Graphite Made From Coal

Graphite, the commonest use of which is seen in the "lead" pencil, is almost pure carbon. This mineral is therefore only a step removed from coal and in fact some of the natural graphite deposits are found in coal beds where the intrusion of masses of intensely heated liquefied igneous rock has metamorphosed the coal, thus forming graphite. An example of this natural manufacture of graphite out of coal is described in one of the reports of the U. S. Geological Survey on the Raton Coal Field of New Mexico. On the other hand, large quantities of high-grade graphite are artificially manufactured direct from ordinary coal.

In making lead pencils the graphite is mixed with a clay of fine grain.

Steel vs. Wooden Mine Cars

By D. T. Evans*

> *Steel and wooden mine cars are compared in regard to their capacity, weight and cost, their life, and expense for repairs. The conclusion is reached that the longer life, lower maintenance and increased capacity per pound of tare weight of the all-steel mine car more than offset its higher first cost and will eventually show a considerable saving.*

The importance of the subject of mine-car construction to coal producers everywhere, is so great that whatever may be the relative merits of steel and wooden cars, it is to the interest of all that the matter should receive careful and earnest consideration, to the end that we may adopt without unnecessary loss and delay that style of mine-car equipment best suited to our needs and to insuring the greatest economy in the operation of our mines. We all know the wooden mine car and its many shortcomings. There are probably more different types in use than there are mines, because almost every mine has its own peculiar style, and, indeed, many mines have more than one, so that even were there time and necessity for doing so, it would be almost impossible to discuss the matter intelligently from any but a general standpoint. Therefore, I shall confine myself to a consideration of the material entering into the construction of the cars, rather than to any particular type or style of car.

For several years, I have believed that the cost of maintenance of wooden mine cars is unduly high, and their life unduly short, and have felt that, in self-defense, the mine operators of the country generally would have to either materially change the general construction of the wooden car so as to reduce the cost of maintenance and increase the life, or else resort to the all-steel car. With this idea in mind, and realizing that it was the only sure way to obtain definite information upon the subject within a reasonable time, I designed and had built, in September, 1909, an all-steel car, along the lines of the wooden car then in use.

Construction of a Trial Steel Car

The bottom was of 3/16-in. plate, in one piece, stiffened by a 1x4-in. drawbar, two longitudinal angles to which the sides were riveted, and by the angle-iron belts as well. The front end was made of 3/16-in. plate also, but the sides and rear end were of 1/8-in. material, no wood being used in the construction except the fillers or blocks for the bumpers, which latter were made of heavy 6x6-in. angle iron, riveted to the bottom of the car. This car, being the first one, cost nearly twice as much to build as the wooden cars; it weighed about 300 lbs. less and its capacity, for the same outside dimensions, was about 15 per cent. greater. We watched it carefully for nearly a year, during which time it was never off the track or required a cent's worth of repairs. It was much easier to handle than the wooden cars, and every miner in the mine wanted to load the steel car.

*General manager, the Mount Carbon Company, Ltd., Powellton, W. Va.

Note—Abstract of an article read before a meeting of the Kanawha Coal Operators Association.

It was then decided to build another car of the same general design, but slightly different in details, with a view to facilitating repairs and reducing the cost of construction. The continual use, for a little over eighteen months, of the first car, and six months' service from the second car, although not covering a sufficient length of time upon which to base definite conclusions, convince me that whatever the ultimate life of a steel car may be, it is certainly much greater than that of a wooden car, while the cost of repairs is certainly much less. At this writing, not a cent has been expended in repairs on either of these cars, and to all appearances they are as good as new, with the possible exception of a slight coating of rust on the inside of the cars. I have noticed that those portions of the outside of the car with which the "black-strap" comes in contact are as bright and smooth as when the plate came from the mill. The second car was built at a cost slightly less than 50 per cent. in excess of the cost of wooden cars, and I believe that this can be still further reduced when cars are made in quantities.

I have, in connection with this subject, communicated with a number of manufacturers of steel and wooden cars, and give below the results of my investigation. Steel cars have a much greater capacity than wooden ones of the same outside dimensions. This increased capacity varies, of course, with the design of the car, but it may safely be stated to range from 10 to 20 per cent. The following table will serve to show what this increase is in several types of car of the same outside dimensions:

RELATIVE CAPACITY OF STEEL AND WOODEN CARS OF SAME DIMENSIONS

Wooden Car	Steel Car	Increase, Per Cent.
49 cu.ft.	58 cu.ft.	18
94 cu.ft.	105 cu.ft.	11¾
53 cu.ft.	60 cu.ft.	13
14 cu.ft.	19 cu.ft.	35

The greater capacity is, of course, accounted for largely by the difference in thickness between the plates of a steel car, which never exceed 1/4 in., and the planks of which the wooden car is built, and also, in some instances, by the fact that it is possible to use a much flatter slope on the sides of steel cars, which adds somewhat to the strength of the steel car, while the same construction would weaken the wooden car.

Some Advantages of Steel Cars

For use in low veins, the steel car offers a decided advantage, because its height or general outside dimensions may be cut down considerably and it will still have the same capacity as a wooden car of larger dimensions. This increased capacity of the steel cars means not only a greater amount of coal handled in a given train load, and a consequent lower power cost per ton for hauling, but a considerable reduction in the number of mine cars needed to handle a given output.

I find a great difference in the weights of various steel and wooden cars having the same overall dimensions and it is difficult to make comparisons with any degree of accuracy. In some instances, steel cars are heavier than wooden cars of the same size, in others, lighter; but taking into account the increased capacity of the steel car, it is, I think, safe to say that its weight will average from 10 to 20 per cent. less than the wooden car. One manufacturer has kindly figured out for me the following comparative weights of cars having the same outside dimensions:

COMPARATIVE WEIGHT OF STEEL AND WOODEN CARS OF SAME DIMENSIONS

Wooden Cars, Capacity	Wooden Cars, Weight lb.	Steel Cars, Capacity	Steel Cars, Weight lb.	Gain in Capacity, Per Cent.	Saving in Weight, Per Cent.
49 cu.ft.	2010	58 cu.ft.	1800	18	11.5
53 cu.ft.	1920	60 cu.ft.	1985	13.2	(Incr.) 3
14 cu.ft.	1085	19 cu.ft.	855	35	26

For the reasons given, however, these figures can be regarded only in a general way. Some manufacturers are building steel cars as heavy as the wooden ones of similar dimensions, but of course having greater capacity, and they explain this increased weight by saying that

these heavier cars have improvements such as spring draft gear, improved axle bearings, etc., which, while adding much to the life and usefulness of the car, also add to its weight. It may and doubtless will be found that such improvements, which we must all agree are badly needed, will be of more value than a smaller tare weight, for even so, the result is an improved car, weighing no more than the wooden car and having a considerably greater capacity.

On account of the wide differences in the construction of various cars and the materials used, together with the varying styles of draft and running gear, it is difficult to offer any reliable and definite comparisons of the cost of wood and steel cars. I have, however, been building a wooden car of 49 cu.ft. capacity, without brakes, that cost in the neighborhood of $45 each and have been offered steel cars of the same outside dimensions, but having greater capacity, as follows:

COST OF STEEL CARS

Capacity	Cost Delivered	Increase, Per Cent.
7 cu.ft.	$65.00	45
1 cu.ft.	62.50	38
1 cu.ft.	75.00	66
5 cu.ft.	68.50	52

So that it seems safe to say that the cost of an all-steel car will run from 38 to 66 per cent. more than a wooden one, in some cases more, possibly, especially in case of the addition of improvements in the way of draft gear, running gear or wheels. The manufacturers themselves state the increase of cost to be from 50 to 100 per cent.

If it is fair to assume, however, that the life of a steel car is double or treble that of a wooden car, and that the cost of maintenance is less, and taking into consideration the gain in capacity, and the possible saving in tare weight, with all their attendant advantages, it would seem that the ultimate cost of the steel car will be much less than that of the wooden car.

Mine-car Life and Repairs

Steel cars have been built for more than ten years, and I am reliably informed that some of these cars are still in use with more or less satisfaction. Undoubtedly, though, these cars, as well as those more recently built, are capable of much improvement, as is still the case with wooden cars, and I am inclined to think that if these cars, built 10 to 14 years ago, are still in use, whether satisfactory or unsatisfactory, it augurs well for the coming steel car of proper design, material and workmanship. Four different manufacturers estimate the life of the steel car to be two to four times the life of the wooden cars, and from such knowledge and information as I have on the subject, it seems to me that this is a reasonable expectation.

My own experience with steel cars, limited though it is, goes to show that the repair cost on steel cars will be materially less than for wood. It is possible that new wooden cars may be run for eighteen months without repairs of any kind, though not probable. Certainly at the end of that period, they would not look practically as good as new, but this has been my experience with the steel car.

We know that in a comparatively short time the bolts in a wooden car will corrode and work loose with consequent disarrangement of the alinement of axle centers, etc., and when repairs are made, in nearly every case, the nuts have to be split or the bolts cut in order to get them out. Frequently, too, the holes in the wood are worn to such an extent that the new bolts hold little better than did the old ones. In the course of time, the bottoms, sides and ends splinter or rot out; in fact, it is my experience that a wooden car that will run for five years without rebuilding is an exceptionally good car, while most of them will not run more than two and a half to four years.

The steel cars, on the other hand, always remain tight and do not warp and shrink as the wooden cars do, and consequently the fine dust does not sift out along the haulways, requiring later on to be moistened and eventually cleaned up.

The manufacturers claim that the cost of maintenance of steel cars is only about 20 to 25 per cent. of that for wooden cars, and from what I know and from the experience of the railroad companies with their steel-car equipment, I think that this cannot be regarded as an underestimation.

General Considerations

Some manufacturers advocate the steel car with wooden bottom, claiming that the wood serves as a cushion to relieve the heavy shocks to which a mine car is subjected, especially in motor hauls. My own experience is that this argument is not well founded. I think that with proper construction, the steel bottom will meet every requirement. Personally I think that if this argument was sound, the advantage of the all-steel car would be minimized, because I believe most people have more trouble with the car bottom than any other part of the car—bumpers knocked off and broken by derailments or jacking, and disalinement of axles, due to wear of bolts and wood. In mines, however, where the coal is excessively high in sulphur, it might be found that the wooden-bottom steel car was advisable, but otherwise I am convinced that the all-steel car is greatly to be preferred.

The manufacturers of steel cars claim also cleaner and freer dumping for their cars, which would be undoubtedly true, so long as the inside of the car was reasonably free from incrustation, and while touching upon this point, I would like to call attention again to the fact that those parts of our steel cars with which the "black-strap" has come in contact are as bright and clean and free from rust as the day the iron left the rolls. I trust that in some way this may serve as a suggestion that will enable someone to evolve a plan for entirely doing away with the rusting of steel cars, though personally I fear it will not be feasible to do so in so far as the insides are concerned, because any application of preservative would soon be scraped off by abrasion in the dumping of the coal.

To briefly sum up my conclusions on this subject I would say:

1. That although the first cost of the steel car is greater, the increased life and decreased cost of maintenance, together with increased capacity, thereby necessitating a fewer number of cars to handle a given output, more than make up for the difference.

2. That the advantage of the steel car having a greater capacity with the same outside dimensions, or the same capacity with smaller dimensions, is of great value, especially in low veins.

3. The increased capacity of the steel car should materially reduce the cost of haulage, and incidentally tend to increase the output of the miner.

4. The saving it is possible to effect in the tare weight of the car itself would also be a factor in the reduction of costs by reducing the proportion of dead to live load.

5. The steel cars will not warp, shrink or split, which are advantages that are apparent to all, besides preventing the leaking of dust coal on haulways—not only a nuisance, but a constant source of danger and expense.

I am personally convinced that the steel car is here to stay. To those who anticipate the use of these cars I would recommend that they spend some time and money in the investigation and trial of a few cars that have been carefully designed to meet the conditions, before making extensive purchases. In buying, I would be careful to see that all parts of the car were made to templet so that when repairs did become a necessity, interchangeable repair parts could be kept on hand and the work of repairing done with comparative ease and speed by the repair men generally found at a mine shop.

Coke Production in W. Va.

In most of the coke-producing States, the coke output for 1910 exceeded that of 1909. In West Virginia, however, the output decreased 140,067 short tons, or 3.55 per cent. The number of coke ovens were reduced from 20,283 to 18,912, the number of idle ovens increased from 2274 to 2590. Nearly all the ovens of the State are of the beehive variety.

COAL AGE

Discussion at Institutes

The close of the winter sessions of the various mining institutes marks a fitting time for a discussion of the means whereby their activity may be quickened and made more valuable. So far it has been customary for certain of the members to prepare papers a few hours before the institute convened, the titles of the papers being set forth on the semiannual program before the articles had been written or the illustrations prepared. The result may be foreseen; the discussion is never well considered, and to the lack of eloquence of the average technical man are added the diffidence and uncertainty of one who has given no thought to what he has to say.

It is a credit to the institutes that, at all of them, are so many men found who can say, and say well so much that is of value to the members in attendance. But what has been said, would have been uttered more correctly, assuredly and exactly had the attending member known in advance what subject would raise him to his feet. To make matters worse his redundancies, faulty wording, errors, verbiage and colloquialisms have been forever embalmed and preserved in a book, euphemistically dubbed "proceedings."

The halfday's discussion at the last meeting of the Coal Mining Institute of America revealed that there was a demand for discussion. After the stiffness wore off, the speakers needed discouragement rather than urging, and it must be admitted that the remarks made were pithy, valuable, and to the point. Some which were not given for publication, and which cannot, therefore, appear in the proceedings, were both new and valuable, eliciting much interest. It was decided to hold a discussion at the summer institute of like character, the subjects to be suggested early and to be announced at least a month before the institute convened.

But why grant the discussion of the questions in the query box an importance which is not given to the discussion on the papers? These should be printed and sent to the members a certain definite time before the date of the meeting. Those who would then read them would come primed with all necessary information, both of what was to be said and what they had to say about it. There is little question but what the prospect of discussion draws an interested audience more surely than the papers, however excellent they may be.

The members who contribute articles are as well able to prepare them for November or April as for December or May. The date can make but little difference and it is likely that regardless of the day set, the papers will be prepared just a day or two before they are needed.

The coal-mining institutes are growing. None too soon can they take on the customs of those larger institutes which cover broader fields.

The Laboratory and the Mine

Few practical men comprehend or are willing to admit the value of the laboratory to the mine. An extended practical experience unaided by an early educational training invariably develops a callousness in the mind of its possessor that is akin to prejudice.

It will be readily admitted by all that few traits of character are harder to combat than an ingrained natural prejudice of mind in favor of one's own methods and kin. Nothing but downright ignorance of men so obstructs the road to progress and improvement as a prejudiced mind.

The mine superintendent or foreman who boasts of a life-long experience in the mines of this and other countries must not fail to recognize the fact that "the world does move," and to keep up with the procession, he must advance. There is much to be learned.

The most successful men today, in all trades and professions, are the men who are touching elbows with other men—studying their ways and learning what they can from their successes or failures. Read, study, investigate, experiment, to find better ways and improved methods.

Regard no man as so inferior but that in some way he can contribute to your fund of knowledge. If nothing else, you can learn a lesson from his failure. So much for the practical side—what about the theoretical side of mining?

It is the province of the laboratory to study the nature of things; to ascertain, as far as may be possible, the laws and principles that control matter. Nature's laws are inexorable, and whether we regard them or not they act with perfect indifference to our folly or ignorance.

Too frequently, it must be admitted, the worker in the laboratory is a pure theorist. He may successfully fathom a mystery of science and define a great natural law; but, because he is unfamiliar with mining conditions and has no mining experience, he fails absolutely in his attempted application of such laws or principles to mining work. He becomes the butt of ridicule among practical mining men. He did good work in his own sphere, but he failed to adapt and apply the same to practical conditions as they exist in the mine.

There are many illustrious examples, however, that prove the value of the laboratory to mining. Foremost and chief is the never-to-be-forgotten discovery of that great English chemist, Sir Humphry Davy, who in 1815 proclaimed to the world the wonderful fact that wire gauze would not permit a flame to pass through its mesh as long as the metal was reasonably cool. The application of this scientific truth to the needs of a gaseous mine made the Davy lamp the greatest boon in the annals of mining.

There are many failures in the attempt to apply scientific laws and principles to practice. The fault is not with the science, but in the failure to understand the physical conditions. Conditions, in mining and elsewhere, are supreme; they are the first consideration in the application of scientific truth.

The attempt to apply the column formula to mine props fails because of the peculiar roof action in mines. It is well known that a uniformly-loaded beam will support a greater load than a beam loaded at the center; but this is no reason for wedging a cross-bar, in a mine, its entire length, which would be contrary to mining practice and would break the beam. It is wrong to apply a pump formula to a mine siphon—it may work and it may not.

First understand the conditions, then apply the principles and laws of science that meet those conditions. Because a ventilating fan has a certain manometric efficiency at one mine, is no reason to suppose that a fan of the same type and build will have the same efficiency, even when running at the same speed, at another mine. It may and it may not, depending on the conditions.

It is a practical failure, as was proven some years ago, to attempt to establish a mine-signal system in the mine workings by installing a device that would act to transmit an alarm from any given point or number of points in the mine, to the office on the surface, whenever an undue accumulation of explosive gas should occur. The theory is perfect; but when it is remembered that the most dangerous accumulations of gas are those that occur in the least expected places, and that the points of danger cannot generally be pointed out and are constantly changing, it is easy to see that any established system of signaling by automatic devices would present a false feeling of security in the mine, and tend to decrease that *eternal vigilance* that is essential for safety.

Treatment of Mine Timbers

It is only in recent years that coal-mining companies in America have come to realize that there is a serious side to the problem of supporting roof in mines. Not only have statistics driven home the fact that the majority of fatalities underground are due to falling roof, but attention has been called to the necessity of either economizing with our timber supply, or finding a substitute for the wooden props now so generally used.

A few of our larger companies have started reforesting in the hope of providing relief in future operation. However, the considerable increase in the cost of mine timbers that has lately occurred in many fields, has made it urgent that some practical and immediate relief be provided.

Because of an earlier and more urgent need, European operators have investigated the "preservation of mine timbers" in great detail. The subject is one that requires 15 or 20 years of experimenting before conclusive results can be obtained; as a consequence, the data submitted by our friends across the water are sure to be both interesting and valuable.

At one mine where creosoted timbers were set in 1900, the props are still in fair condition while the untreated timbers near-by have been replaced twice. It is the opinion of the owners of this mine that a set of creosoted props will last as long as three sets of untreated timbers.

It isn't alone the cost of mine timbers that an operator must consider; there is also the expense incurred when new props are placed. In fact, a record of the charges against replacement, recently calculated by the officers of one operating company, showed conclusively that the cost of setting new timbers, when estimated for a long period of years, was approximately 30 per cent. of the total charges marked up against timbering.

As to which of the various methods of preservation is most satisfactory, the data to hand seems to favor cresote as a medium of greatest merit. At a recent meeting of European mine operators where the subject of preserving timbers was discussed, the consensus of opinion favored the creosote process of impregnating timbers, and showed further that the sulphate-of-copper method was of highest annual expense.

The tabulated results of one investigator on this subject follow:

TREATMENT OF MINE TIMBERS

Process	Average Life of the Timber	Annual Cost per Cubic Meter of Wood
Sulphate of copper	11 yr. 7 mo.	$0.82
Chloride of zinc..	11 yr. 9 mo.	0.78
Creosote.........	20 yr. 6 mo.	0.58
Mercuric chloride.	13 yr. 7 mo.	0.44
Untreated timbers	7 yr. 7 mo.	1.02

An English authority on the use of safety helmets in rescue work, claims to have found, on investigation, that the oxygen cylinders sold for use in connection with breathing apparatus are often of inferior quality.

After a thorough examination, he has discovered that these cylinders contain as high as 12 per cent. nitrogen, and that most of them contain 5 per cent. It is claimed that 5 per cent. is dangerous for use in helmets, as it is liable to accumulate in the breathing bag until there is 90 per cent. nitrogen and only 10 per cent. oxygen, when the breather becomes unconscious without warning.

It appears to be possible to manufacture these cylinders with 99 per cent. oxygen, at a reasonable cost, and we believe that legislation on this point would not be inappropriate. The matter is certainly of vital importance to coal men.

COLLIERY NOTES and COMMENTS

Practical Hints Gathered Here and There, and Condensed to Suit the Busy Reader

The employment of a deputy foreman for every 50 miners employed, whose duty it should be to examine all working places at least once during each shift, to inspect all timbering, to oversee the drilling of holes and firing of shots and report on the same to the foreman, would add much to the safety of gaseous mines or mine with a poor roof.

Undercutting before firing means fewer holes required to break down the coal; less powder required; less slack; easier separation of bone and dirt from the coal; less interference with the timbering; less roof damage; easier and quicker loading; less weathering of coal during shipment; greater profit, since the coal is cleaner; and last but not least, fewer accidents.

The compulsory use of electric safety lamps, about mine stables and other buildings of an inflammable nature or containing inflammable material, would do much to lessen the danger from fire. They should also be used in very dry sections of mines where the timbering is heavy, and by timber men working in main headings and slopes. Their use by firebosses, for roof examination and such like work, would mean additional safety to miners and to the fireboss himself.

The quality and structure of coke depend on the composition of the coal and the heat to which it is subjected. A coal high in volatile matter makes a light, porous coke. A coal of high fixed-carbon content and of low volatile matter will produce a dense, heavy coke. When these two classes of coals are combined in a byproduct oven so as to give an average percentage of volatile matter, the best results are obtained, because the mixing overcomes the defects of the cokes made separately from either of the coals.

According to the United States Geological Survey the total exhausted portion of our coal supply, figuring one-half a ton lost for every ton marketed, down to the close of 1908, represents only 0.4 of one per cent. of the estimated original supply. At the present rate of exhaustion the coal supply of the United States will last nearly 5000 years, but if the rate of increase keeps up during the remainder of this century and the next century, exhaustion will be reached in less than 200 years. The average increase in the production of coal for the last 10 years has been between 6 and 7 per cent.

Hard pitch, rosin and cements make hard brittle briquets. Creosote, asphalt and coal-tar briquets are not brittle, but are easily crushed under pressure. The binder that produces briquets most capable of standing rough handling is one that can be twisted and pulled at an ordinary temperature, one that flows slowly and has sufficient elasticity not to be brittle, and stiffness enough not to be affected by the weather. Water-gas tar pitch, asphalts, wood-tar pitch and wax tailings make good briquets with the use of only 3 to 5 per cent. of binder.

At a meeting of the South Staffordshire Mining Engineers, F. B. Clark gave it as his opinion that in cases where cables have to be carried along dry, dusty, or gaseous roads, lead-sheathed and armored cables, or other double-sheathed varieties, should be adopted to prevent external arcing. Where cables have to be led along such roads, the safest method is to place them in a steel troughing filled with sand, and bury them at the side of the road. An armored cable will thus be rendered absolutely safe, for even if arcing appears outside the armoring, it is still covered by the sand, troughing and earth.

It is recalled by W. C. Blackett that about the year 1676 the Hon. Roger North referred to the "damps or foul air" of the coal mines. The suggestion of Mr. Blackett before the Institution of Mining Engineers is that Dr. H. S. Haldane's idea for the use of mice or birds in testing for carbon monoxide (and this most valuable expedient is likely to save more lives than any of the so called rescue equipment) may be said to have been to some extent forestalled by this early writer, who stated that "damps, or foul air, kill insensibly," and that "an infallible trial is by a dog." Again T. Y. Hall, in 1854, suggested the use of "some living animal" for the purpose.

It is interesting to be reminded that Lehman found that 1/1400 of H_2S, sulphureted hydrogen, in air was sufficient to cause death in an hour or more in various animals and also in man. He describes a case showing alarming symptoms produced in a few minutes by air containing 1/2000 part. He also found that one part of H_2S in 500 parts of air was sufficient to kill dogs and cats in 90 seconds. Unlike most mine gases, the symptoms of this gas on the human system are those of an irritant poison. Its characteristic smell resembles that of rotten eggs, and it has been ascertained that the presence of this gas in quantity appears to overpower the sense of smell.

In Britain the advocacy of portable electric lamps for miners is gaining ground, although only two or three collieries have employed them. It is pointed out that the advantages of this type of lamp are important. By comparison with the best safety lamp it gives a superior light. At any rate for a short time it can be held in any position without danger of extinction. Third, although it has been pointed out that an explosive mixture may be ignited from a portable electric lamp, it would be very much more difficult than with the "safety" and with a properly designed lamp almost impossible to do so. But failure to indicate the presence of gas, and the much greater expense are disadvantages of the portable electric lamps.

The Lehigh Valley strippings at Lattimer, Penn., are over half a mile long and from 500 to 900 ft. wide. Two veins have been uncovered which are estimated to contain 1,500,000 tons of high-grade anthracite. The upper or Mammoth vein has an average thickness of about 30 ft. without partings. The lower, or Warton vein averages about 9 ft. in thickness. Preliminary work on the stripping began in 1901. Coal was first won in 1904. The excavation is now down to an average depth of 80 ft. over the entire stripping. The cost of operations up to the time the first coal was taken out is estimated at $495,000. The amount of rock and clay overlying the coal is estimated to have been 5,000,000 cubic yards.

The mine foreman of a rescue station should remember that experience has shown it is impossible for men to work where the wet bulb registers 85 deg. F. without a rise of temperature and danger of being overcome by the heat. The dry bulb temperature does not much matter, but the power of the human system to regulate its temperature depends almost entirely on the humidity. Men should not be exposed for more than 30 min. if the temperature is over 80 deg. F., as in hot, wet air the temperature of the body cannot be kept down by the evaporation of sweat. Men working in such an atmosphere should dispense with as much clothing as possible, and should be supplied with apparatus having a detachable mouthpiece, so that by drinking often they may perspire more profusely.

SOCIOLOGICAL DEPARTMENT

A Bureau Devoted to the Welfare of Miners Everywhere, and Especially Designed for the Betterment of Living Conditions In Mining Communities—COAL AGE will be Glad to Print Any Suggestions or Ideas of Value to this Department

Cleanliness

By F. A. Boag

When all is said and done toward the improvement of mining towns, it will be found that cleanliness is the most uplifting force of all. We are apt to regard the unkempt appearance of mining villages as the fault solely of the tenant, and indeed many of them accomplish wonders in the soiling of their homes and of the face of nature by unsightly outhouses and fences, and accumulations of plunder and garbage. But perhaps we too often overlook the fact that the untidiness is due primarily to unfavorable conditions and secondarily to the psychological effect those selfsame conditions have on the tenant.

Byproduct Ovens and Smokeless Furnaces

It is, of course, hopeless to expect clean towns where beehive ovens are in use. Nevertheless the location of the town where the prevailing winds cannot carry smoke to the houses will materially aid in reducing the dirt caused by the effluence of smoke during the early stages of devolatilization. The use of byproduct ovens will do yet more to enable the operator to keep a spotless town.

But the unnecessary sootiness of a hamlet where there are no coke ovens is one of the deplorable facts of coal mining. Injudicious firing, by which the firemen waste the coal of the company, and begrime the houses in which they and their neighbors live can be found unchecked and often unrebuked at nine bituminous plants out of every ten. If the coal used at such plants is of such size or quality that the waste does not impose a measurable loss on the company, nevertheless for cleanliness' sake, such firemen should be admonished or removed.

Producer Gas

At many mines, a large percentage of bone coal is extracted. Part of this bone is brought to the surface either with the rock of the headings or mixed in with the coal. This bone coal is thrown in unsightly piles around the works either with rock or alone. In places where slack is not used under boilers much of it is often stored during the summer months to be shipped out in the winter. Both bone coal and slack are subject to spontaneous combustion and when fired they fill the valleys with smoke and with the pungent odors of the oxides of sulphur. It would seem desirable to install producer plants, so that the bone and slack could be immediately used for the manufacture of gas. This gas might be used in the power plant for gas engines or it might replace coal in domestic fires and oil in house lamps, the sale of this gas being made a profitable business. It would also make the town a more desirable place in which to live, bringing some of the advantages of the city to those who have hitherto not enjoyed them. But it must be admitted that to date the use of producer gas for lighting and heating has not as far as I know been pursued to a successful commercial culmination.

A Lowland Town

I once knew a superintendent who said he wanted to build his houses so near the mine that the men could crawl out of their beds into crop-holes of the workings, and after his town was laid out, there seemed considerable appositeness in his remarks. The result was apparent. The town was set down in an inaccessible hollow; the roads entering it from the hills were unsafe to travel because of their location on the stiff slopes; heavy rains washed mud onto the townsite, making the pathways impassable after a heavy rainfall, and all the dust from the tipple and passing cars, and all the smoke, soot and exhaust steam from the power house drifted in on the town. Such a town could not be clean and the miners could not possibly have promptings toward cleanliness with such undesirable surroundings. Neither trees nor gardens could thrive in such an atmosphere.

Two sites may often appear equal in desirability till after a washer and coke ovens are erected, and a rock dump begins to erect its somber head. The washer may fill up the whole valley with a dirty wash in which no tree can live. The rock dump may keep fine dirt continuously rattling down in the immediate rear-ground of the houses. New steam and electric roadways may have to be created, cutting up the back yards. These roadways destroy all privacy and quiet and in many cases the locomotives add to the general uncleanliness.

It is true that men who have wet work to perform around the mines object to long trips in their wet clothes and that in winter the "drill" from the mines to the village is a cold and chilly one, but it will probably be found that families will choose the houses which are more remote from the mines than those so near that clothes must be dried indoors and windows kept shut because of the grime with which the air is laden.

First Aid Banquet

At a banquet in Pittston, Penn., Dec. 9, held jointly by the First-Aid Corps of the Pennsylvania Coal Co., the Hillside Coal & Iron Co. and the Temple Coal & Iron Co., Dr. J. B. Mahon was presented with a gold-headed cane. The presentation of the handsome cane came as an agreeable surprise to Dr. Mahon and was one of the evidences of the high esteem in which he is held. It was in appreciation of the valuable services rendered by the doctor, who has been medical instructor of the corps since Dr. Shields resigned some years ago.

The large number of men who gathered was an inspiring sight and many words were spoken in praise of the bravery and heroism of those who risk their own lives to help their fellow men when they meets with accidents in the mines. There were all classes of workmen in the assemblage, foremen, superintendents, miners and laborers, all interested in first-aid work. About 350 sat down to the banquet. Capt. W. A. May, general manager of the Pennsylvania and Hillside Coal & Iron companies and largely instrumental in forming the First-Aid Corps, was present and spoke appreciatively of the value of first aid and of the members of the corps.

Other speakers were Dr. Newring, D. M. Howell, secretary of the Pittston Y. M. C. A., and Dr. Arnott, the new instructor, who is to take the place of Dr. Mahon. The last exhorted the men to continue in the good work and said that he felt much encouraged from the interest manifested and would give all his attention to maintaining the high standard of efficiency that the corps has held. Judge Ferris was toastmaster.

First Aid Hint

Ordinarily, do not give brandy or whisky to a person suffering from shock, though if some time must elapse before the patient can reach the surface or underground hospital, and there is no severe bleeding a teaspoonful of brandy or whisky in a tablespoonful of hot water may be given every fifteen minutes. Alcoholic stimulants should be handled with care because of the depressing effects of an over-dose.

DISCUSSION by READERS

Comment, Criticism and Debate upon Previous Articles, and Suggestions from the Experience of Practical Men

Anshracite Coal Inspection

I was greatly interested by Mr. Dorris' article on anthracite-coal inspection in the Dec. 9 issue of COAL AGE. I quite agree that the inspection of coal in this region is being greatly enlarged in its scope and has made good progress in applying general standards to the quality of coal prepared for shipment. But when Mr. Dorris says, in speaking of the inspector: "When his decision is rendered, based on actual tests, no one questions his authority or the correctness of the tests," I think there is some room for objection. I am not one of the foremen who "endeavors to convey this impression to the superintendent," and I believe the authority of the inspectors is now well established and undisputed, but it seems to me that the correctness of the tests may well be questioned.

To begin with, it is not an unknown thing around here when cars of condemned coal are sent back for repreparation, to have the boys under the breaker pick off a few lumps of slate or bone, wash the top down with water from a hose, and have all pass inspection without further ado. I don't say this is usual or that it is ever countenanced by even the foreman, much less the company's officials, but it is possible nevertheless.

It stands to reason that a 100-lb. sample dug out of a 50-ton battleship, even if it is taken from four or five, or eight or ten different places, does not represent the contents of the car. If we are unlucky enough to empty a pocket in loading a car, of course we get a lot of dirt on top of a carload of perfectly good coal. Not that a carload of this kind should go to market, but the fact serves to show that mistakes may be made even by actual tests.

The better way to take samples is usually considered to be at the loading chute while the car is being filled, but even here the inspector, by holding his pan into one part of the stream can usually get all good coal, and by holding it in another part, more directly under the lip of the chute, can get little beside slate and dirt. There is still a lot of chance for the personal element to enter into the question.

For my part, while I believe in keeping up to a standard of preparation, it still seems to me that the expense for rehandling condemned coal through the breakers is often hardly justified. The sales department is making the operating end step around pretty lively, of late, and there ought to be a limit somewhere short of wrapping each lump in tin-foil, and packing it away in excelsior. It looks to me like a case of the tail trying to wag the dog. If the alleged anthracite combination is good for anything, why don't they get together and agree to furnish only the kind of coal that can be most economically prepared, and give the consumer the benefit of a corresponding drop in price?

It costs a lot to pick a few extra pieces of bone out of a car of coal, and the public ought to be educated to the idea that fuel does not have to shine and sparkle in order to burn, and burn to good purpose at that.

Wilkes-Barre, Penn. FOREMAN.

The Explosion at Vivian, West Virginia

I was much interested in your account of the explosion in the mine of the Bottom Creek Co., at Vivian, W. Va., as I know something about the mine. I notice in the sketch you publish, that there were three breakthroughs between the room where the explosion is supposed to have occurred and the next one outside, above the point where the engineers are supposed to have fired the gas. I cannot see how such a body of gas could have been standing in that room with a current of air traveling through it. Can you explain it?

I am looking forward to your account of the recent explosion in Tennessee.

GEORGE D. EVANS.

Pottsville, Penn.

[Mr. Hall, who visited the Bottom Creek mine after the explosion, and who prepared the description that was published in COAL AGE, answers your question below.—EDITOR.]

I understand that there was, at one time, in the haulway of the 11th entry, a curtain between the two rooms mentioned, but I could not find whether or not it was still in place at the time of the explosion. Mr. Patterson informed me that it had been there. It probably was no longer in place or the gas would not have accumulated. You will understand that the rooms were abandoned with the intention of not working them for a year at least. They were standing awaiting the driving of rooms intermediate between those already driven and the drawing of the pillars further along in the large panel inclosed by the first and second diagonal headings and the 10th and 11th entries. The inspector favors the requirement that all such disconnected rooms be driven up to the airway of the entry above so that the ventilation may not be left to the chances of negligence.

Best Type of Rescue Apparatus

There is considerable difference of opinion as to whether the helmet-, mask- or mouth-breathing type of rescue apparatus is the best fitted for mine-rescue work. Some authorities claim that the helmet is best adapted for work in smoke or fumes irritating to the throat, eyes and nostrils, rather than in poisonous, nonirritating, unbreatheable gases, where mouth-breathing apparatus should be used. A leak in a helmet used in nonirritating, poisonous gas is not readily detected and may result fatally to the wearer, whereas a leak in a mouth-breathing apparatus is readily detected. The examination of roofs is easier and more quickly done with mouth-breathing device than with helmets. I would like other rescue men to express an opinion.

Trinidad, Colo. FIRST AID.

Price Cutting in West Virginia

The question of prices is the one absorbing topic at present in the West Virginia coal field and has been discussed at several recent meetings of the operators, but as yet no decided step has been taken to bring about an improvement in conditions. It is a strange anomaly that while wages and prices of all commodities and supplies have gone up, the price of coal at the mine has decreased and is now at the lowest point reached for several years.

For this fact the operators are to blame and they alone can furnish the remedy. Lack of business sense and jealousy of those who have striven to improve selling conditions on the only rational and abiding basis possible, have combined to bring the coal business in this field to the worst stage it has ever reached.

The situation has been fostered and made worse by certain of the New England sales agencies who are interested in keeping down the price of coal for their own purposes.

A Mine Siphon

We have a problem under discussion which we wish to submit to COAL AGE for a solution. It is as follows:

There is a large pond of water, in a mine, which it is desired to drain by means of a siphon, using 3-in. pipe for the purpose. The pipe must be laid in the entry, a distance of 1000 ft. from the pond to the top of the hill, where the elevation is 24 ft. above the bottom of the pond. In this stretch the pipe makes one right-angle curve. From the top of the hill the pipe extends 550 ft. to the point where it discharges the water. The elevation of the point of discharge is 34.66 ft. lower than that of the top of the hill, or 10.66 ft. below the pond.

If a siphon will fail to operate successfully under the conditions stated above, as some claim it will; and if successful operation can be secured by making any minor changes in the proposed arrangement, will COAL AGE or any of its intelligent readers kindly suggest what changes are, in their opinion, necessary.

HOWARD L. GREGG.

Tracy City, Tenn.

Owing to its simplicity and low cost of installation and operation, the siphon, as used in mining, is of great importance. Of all the useful principles with which mining men should be acquainted, probably none are less understood than the principle of the mine siphon. The reason for this is that the flow of water in the siphon is generally assumed as being identical with the flow of water in any pipe, under a given head. This is only true when the conditions are such that the effective head that causes the water to flow up the suction leg of the siphon is sufficient to supply the water at the summit or crown as fast as it flows away from the crown and is discharged at the lower end of the pipe.

It is necessary to observe that the supply of water at the summit S (Fig. 1) is limited by the atmospheric pressure, which is partly balanced or absorbed by the gravity head h_1 and the frictional resistance in the suction leg of the pipe. The discharge, on the other hand, depends on the gravity head or fall h_2, less the friction head in that end of the pipe. It is easy to see that under certain conditions of atmospheric pressure and suction head, combined with a great length of pipe on the suction end, the flow of water to the summit of the siphon may be much less than what is required to give a full pipe under the velocity of discharge. In such a case, the water will flow away from the summit faster than it is supplied to the summit; and, as a consequence, the siphon tends to empty itself.

It is clear, also, that the effective head on the supply or suction end, may be much less than the head due to the atmospheric pressure. For example, at sea level (bar. 30 in.), the head of water due to atmospheric pressure is $\frac{30 \times 0.4911}{0.434}$ = say 34 ft. For any elevation above sea level the atmospheric head must be calculated, in this manner, from the barometer reading.

Fig. 1 shows the relation of the atmospheric head and gravity head acting on each end of the pipe. On the suction end, the gravity head acts against the atmospheric head. The difference $H - h_1$ is the head producing the flow in this end of the pipe, and must equal the friction head plus the velocity head $0.0026\,\frac{G^2}{d^4}$, as calculated, for ordinary mining conditions, by the formula

$$H - h_1 = \frac{l_1 G^2}{800\, d_1^5} + 0.0026\,\frac{G^2}{d_1^4}$$

and

$$G = d_1^2 \sqrt{\frac{800\, d_1\,(H - h_1)}{l_1 + 2.08\, d_1}}$$

G = Flow of water in pipe (gal. per min.);

l_1 = Length of suction pipe (ft.);

d_1 = Diameter of suction pipe (in.).

On the discharge end, the atmospheric head acts against the gravity head; and the difference $h_2 - H$ is the head producing the flow in the discharge pipe, which is equal to the sum of the friction and velocity heads in this end of the siphon, as found by the formula

$$h_2 - H = \frac{l_2 G^2}{800\, d_2^5} + 0.0026\,\frac{G^2}{d_2^4}$$

and

$$G = d_2^2 \sqrt{\frac{800\, d_2\,(h_2 - H)}{l_2 + 2.08\, d_2}}$$

The siphon is working to the best advantage when G is the same in each leg of the siphon. If the value of G is greater for the discharge than for the suction, the water will flow away from the summit quicker than it is supplied at that point; and the siphon tends to empty itself, which it will do, in time, whenever h_2 is greater than H. The siphon cannot empty, provided all pipe joints are tight and the ends are completely submerged, when h_2 is less than H, except by allowing air to accumulate at the summit. There should be an air-trap arranged wherever there is a high point, except in pipes where the flow is so strong that the air has no opportunity to accumulate. This is generally the case when the siphon is properly designed.

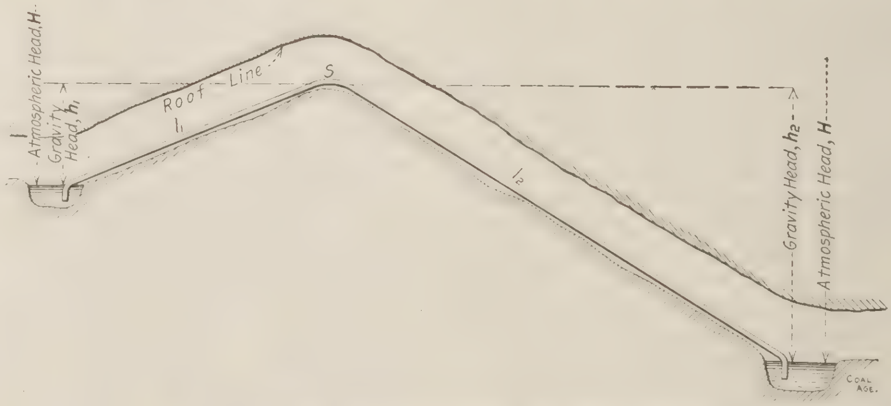

FIG. 1. SECTION OF MINE ENTRY, SHOWING SIPHON

If the value of G is greater for the suction than for the discharge end, the siphon will work satisfactorily; but it is not doing its full duty, because the discharge pipe is too small and throttles the flow, of which the suction end is capable.

A PRACTICAL SOLUTION

To show the practical application of the principles just explained, let us investigate the conditions under which the 3-in. siphon mentioned by correspondent must operate, and ascertain if there is any improvement to suggest.

The elevation of Tracy City, Tenn., where the pipe is located, as given by the

"Dictionary of Altitudes," U. S. Geological Survey, is practically 1100 ft. above sea level. The average barometer reading for this elevation ("Mine Gases and Explosions," Beard, p. 88), is 28.757 in. The corresponding atmospheric head in water column is

$$H = \frac{28.757 \times 0.4911}{0.434} = 32.54\ ft.$$

From the data given, $h_1 = 24$ ft.; $l_1 = 1000$ ft.; $h_2 = 34.66$ ft.; $l_2 = 550$ ft.; $d_1 = d_2 = 3$ in. Substituting these values in the formulas given for finding the flow for each end separately, we have

Suction flow,

$$G = 3^2 \sqrt{\frac{800 \times 3\ (32.54 - 24)}{1000 + 2.08 \times 3}}$$

$$= 40.59\ gal.\ per\ min.$$

Discharge flow.

$$G = 3^2 \sqrt{\frac{800 \times 3\ (34.66 - 32.54)}{550 + 2.08 \times 3}}$$

$$= 27.09\ gal.\ per\ min.$$

This shows that, while the siphon will work, it can be greatly improved by using a larger discharge pipe. To find the required diameter of the discharge pipe (d_2), equate the two values of G, given previously, and find the value of d_2, by trial. In this case

$$d_2 = 3^2 \sqrt[5]{\frac{32.54 - 24}{34.66 - 32.54}\left(\frac{550 + 2.08\, d_2}{1000 + 2.08 \times 3}\right)}$$

$$= 3.5\ inches$$

If 3½-in. pipe is used on the discharge end of this siphon, the entire 550 ft. from the summit to the discharge its delivery should be increased 50 per cent.

Corrosion of Pump Valves by Acid Mine Water

We have three electrically driven, triplex pumps in our mine. The one at the shaft bottom handles strongly acid water, which eats away the valve seats in from 10 to 15 days. The valve seat farthest away from the connection with the main suction pipe is eaten away the most rapidly. Why is this? We have had an analysis made of the water and from this analysis it is claimed that cast-iron valve seats should satisfactorily resist the corrosive action of the acid it contains. Our experience in this regard, however makes me skeptical. I would value highly the opinion of COAL AGE in regard to the matter.

Marion, Ill. DAVID FULTON.

Your trouble is not unusual; the presence of acid in the water is one of the chief difficulties encountered in pumping at most coal mines. The position of the valve with respect to the suction-pipe connection should have no influence on the rapidity of action of the acid mine water, provided other things are equal. However, a slight mechanical defect in the operation or seating of the valve, as failure to open the required distance or to make a tight joint when closed, might easily account for an increased wear and corrosion, in comparison with a valve that is operating properly. Increased wear assists the corrosion of the metal by exposing fresh surface to the action of the acid water. Perhaps some readers of COAL AGE have had experience in this connection, which will aid in clearing up the point in question. We would gladly have the corrosion of mine-pump valves further discussed. Few subjects are of greater economic importance in mining practice.

It may be said that while cast-iron valves and valve seats are generally superior to iron or steel, for pumping acid mine water, they are decidedly inferior to valves and valve seats made of any of the several kinds of acid-resisting bronze. The bronze is worth about 25c. per lb., which is from three to four times the cost of a finished iron casting. But, as the chief expense in connection with pump valves is usually the cost of labor and loss of time in making renewals and repairs, the use of this special material is generally found to result in a great economy in operating expense.

Acid-resisting bronze is made from various proportions of copper, tin, lead and sometimes antimony. The following composition endured for two years and three months in a pump at Hazleton, Penn., handling water that contained 21.28 grains of sulphate of iron and 31.19 grains of free sulphuric acid, per gal.: Copper, 85.1%; antimony, 6.8%; tin, 6.8%; lead, 1.3%.

Design of Centrifugal Mine Fans

In your issue of Oct. 28, page 87, there is given an example of a fan designed to pass 150,000 cu.ft. of air per min., against a 2-in. water gage, at a speed of 100 r.p.m.; and by increasing this speed to 190 r.p.m. it is estimated the same fan will deliver 250,000 cu.ft. of air per min. and the water gage be increased to 5.5 in. The size of the fan required for this work is given as 15 ft. 10 in. diameter, 5 ft. 7 in. wide with an orifice 8 ft. 11 in. diameter.

I would like to know how you arrived at the diameter of the fan, the diameter of its orifice and its width?

WILLIAM JAMES.

Ladysmith, Vancouver Island, B. C., Canada.

The calculation of the different dimensions of a mine fan, to suit the several conditions under which it must operate, is not an easy task. The diameter of the central orifice is determined by assuming that the air enters the fan through this opening, with a velocity due to the pressure of the atmosphere and against the depression established within the fan by reason of its action.

This solution is complicated; but it is assumed by different fan makers that the entering velocity of the air varies from 1200 to 2500 ft. per min., or may be even greater. Much of the successful operation of the fan depends upon how close this assumption comes to the velocity the atmospheric pressure will actually produce at the entrance to the fan, in any given case. If the velocity is assumed too high the estimated area of intake is too small and the fan is throttled; if the velocity is low the intake area is larger than should be and backlash is the result.

In general, for a double-intake fan, the width of the fan may be taken as ⅝ of the diameter of its central orifice. This rule, again, is modified by certain details of construction that can only be worked out by an expert fan engineer.

The outer diameter of the fan-wheel depends on numerous factors such as the mine potential, or the ratio of the square of the quantity of air to be circulated to the pressure producing the circulation in the mine; the sectional area of the airway or fan-drift where the pressure and velocity of the air are measured; the velocity and density of the air at that point; and the speed of the fan and a factor known as the fan-constant, which depends upon the style of fan.

These determinations can only be worked out, for any given case, by a fan engineer to whom we would refer our correspondent. The conditions in every case, in mine ventilation, demand and should receive separate treatment by an engineer who understands them, in order to insure the successful and economical operation of the fan in the emergencies that are prone to arise in mining practise.

Coal Mining in Scotland

Please state a few general facts concerning the coal industry in Scotland.

Springfield, Ill. F. R. B.

In Scotland, out of a population of 5,000,000, more than 500,000 are directly or indirectly dependent on mining for their living. Scotland has 481 coal mines in operation, which give employment to 123,214 men and 2684 women. From five to ten tons per day is the average output of a man and two boys. The miners work in three shifts of eight hours each, and upon notice can take a holiday at will. The minimum wage for men is $1.46 per day of eight hours; the maximum is $1.92. The weekly time averages less than 48 hours, giving a wage of from $9 to $11 per week. On piece work first-class miners sometimes make $15 per week.

EXAMINATION QUESTIONS and ANSWERS

To Encourage, Assist, and Instruct Those Preparing for Firebosses, Mine Foremen, and Inspectors Examinations, Selected and Original Questions Are Carefully Answered And Fully Explained

Interesting Questions

Diffusion of Gases

(*Continued from p.* 319 *of the Dec.* 16 *Issue of* COAL AGE)

Ques.—(*c*) Show the application of the law of the diffusion of gases by finding the relative volumes of marsh gas (CH_4) and carbon dioxide (CO_2) in the mixture of these gases formed under such conditions that the undiluted gases diffuse into each other without becoming, first, mixed with air.

Ans.—(c) Applying the law of diffusion to find the composition by volume of a mixture formed by the diffusion of marsh gas and carbon dioxide, the relative volumes are inversely proportional to the square roots of the densities of these gases; or, the volume ratio is equal to the square root of the inverse density ratio. Thus,

$$\frac{Vol.CH_4}{Vol.CO_2} = \sqrt{\frac{Sp.gr.\ CO_2}{Sp.gr.CH_4}} = \sqrt{\frac{1.529}{0.559}} = 1.65.$$

Then,

Relative volume CH_4	1.65
Relative volume CO_2	1.00
Relative volume of mixture	2.65

The percentage of marsh gas in this mixture is

$$\frac{1.65}{2.65} \times 100 = 62.3\%.$$

This mixture is lighter than air; its specific gravity is calculated by multiplying the relative volumes of the two gases, as found above, by their respective specific gravities and dividing the sum of these products by the relative volume of the mixture. Thus,

$$1.65 \times 0.559 = 0.923$$
$$1.00 \times 1.529 = 1.529$$
$$\text{Relative weight} = 2.452$$
$$Sp.gr.\ of\ mixture = \frac{2.452}{2.65} = 0.925.$$

This mixture is, therefore, lighter than air, and tends to accumulate at the roof, or at the face of steep pitches. It diffuses in air slowly. It contains no available oxygen, and, hence, will quickly extinguish a light. It is extremely dangerous to handle, for the reason that, by the addition of sufficient air, it may become highly explosive.

For example, suppose sufficient air be added to bring the marsh-gas mixture to its maximum explosive point, or 9.57 times the volume of marsh gas. The relative volume of air and gases would then be as follows:

Relative volume CH_4	1.65
Relative volume air, $1.65 \times 9.57 =$	15.79
Relative volume CO_2	1.00

It is clear there would then be 1 volume of CO_2 in $1.65 + 15.79 = 17.44$ volumes of firedamp, at its maximum explosive point. To render this mixture inexplosive would require $\frac{17.44}{7} = 2.49$ volumes of CO_2. This mixture of marsh gas and CO_2 is difficult to detect because it gives a cap, for the first moment only, when the lamp is raised quickly into the gas. The cap disappears at once and the flame dims and quickly goes out as the lamp fills with the gas. The mixture has been called "flashdamp."

Utah Mine Foreman Examination Questions

Gas Feeder

Ques.—How is it possible to deal with a strong feeder of gas in the middle of a ventilating district, so as to provide for continuing work in the remaining portion of the district?

Ans.—The manner of dealing with this feeder so as not to interfere with the work in that portion of the district affected by the return, will depend on the conditions surrounding the feeder and its location with respect to the intake and return air-current. The general plan of procedure, however, in such cases, is to wall in the feeder by building a substantial brick stopping about the feeder itself, or in each opening leading to the place in which the feeder is located. A pipe of sufficient diameter is built into the wall or stoppings, and arranged to conduct the gas directly into the main-return airway. In some cases, it would be best to pipe the gas directly to the surface through a drill hole sunk for the purpose.

Gas on Falls

Ques.—Upon making his rounds of inspection in the morning, say in No. 3 entry and Nos. 1, 2, 3 and 4 pillars, the fireboss finds the gas down to the edge of the roof, on the caves (falls). These pillars are being worked with safety lamps, while the remaining rooms and the entries are worked with open lights. (a) What, in your opinion, should be done? (b) Can the above system be made safe practice?

Ans.—(a) Withdraw the men from the rooms, promptly, or make them use safety lamps. (b) The question does not state the direction of the air-current. If the pillar workings are on the *first of the air*, there is grave danger in allowing open lights in the rooms beyond. Safeties should have been used in all these rooms. Even if the pillar workings in No. 3 entry are on the *last of the air*, it would not be safe practice to allow open lights in the two or three rooms next adjoining. In either case, the use of open lights in the rooms, as stated, is unsafe practice, because the heavy roof falls that may occur at any time in pillar workings are liable to drive the gas back into the adjoining rooms, where it would be ignited if open lights were in use there.

Lamp Station in Mine

Ques.—In a mine generating firedamp freely and worked with locked safety lamps, the coal is becoming rapidly exhausted. It is decided to open up another section, in the same mine, where no gas has been discovered and to use open lights in the new section. What regulation should be made and enforced in order to prevent the naked lights being taken into the fire zone?

Ans.—A lamp station should be established in the entry connecting the two sections of the mine; and a strict rule should be enforced that none could enter the fiery section with anything but a locked safety lamp that has been duly cleaned, examined, filled, lighted, locked and delivered to the user, at said station. The only exception to this rule would be the firebosses, who care for their own lamps.

The regulations should also provide that no one will be allowed to carry or have in his possession a lamp key or other device for opening a lamp, except the firebosses. Also, any lamp extinguished by accident must be returned to the lamp station to be relighted. Any lamp known to be injured must be promptly extinguished and returned to the lamp station.

Means of Detecting Gases in Mines

Ques.—(a) Could you depend absolutely on a safety lamp for the detection of all mine gases? (b) What other methods would you adopt for their detection?

Ans.—(a) No. It is best not to rely wholly on the indications of the lamp. (b) An indicator should be used for marsh gas. A canary bird or caged mouse should be carried to warn against carbon monoxide. Carbon dioxide is indicated with sufficient promptness on the lamps.

COAL and COKE NEWS

Editorial Correspondence from our own Representatives in Various Important Mining Centers, and a Record of Legislative and Other Action Affecting the Coal Industry

Washington, D. C.

Alaskan Land Fraud Case

The supreme court of the United States has reversed and remanded the case of the United States, plaintiff in error vs. Charles F. Munday and Archie W. Shields. In this case, the charge was that the defendants named, conspired with each other to secure for the Alaska Development Co., a corporation of the state of Washington, and the Pacific Coal & Oil Co., a corporation of the Dominion of Canada, coal lands of the United States of approximately 6087 acres in extent and more than $10,000,000 in value. These lands were situated in the Kayak district of Alaska. Various persons, 40 in number, each being qualified to make an entry of coal land, were induced to make entries ostensibly for themselves, but really, it was alleged, as the agents of and for the use and benefit of the two corporations named, with the purpose of securing to the corporations much more coal land than any two persons were entitled to get by entry under the coal-land laws.

There was filed a plea of not guilty, but the defendants objected to the introduction of any evidence and moved the court to direct a verdict in their favor. The court overruled this motion, but upon the sole ground that the Pacific Coal & Oil Co., being a foreign corporation, was not entitled to any coal lands under the coal-land laws of the United States and so the charge in the indictment of a purpose by the defendants to secure lands for this company was a valid charge of an intent to defraud the United States.

Case Brought to Supreme Court

Later on the case was brought to the supreme court by writ of error with reference to the decision of the circuit court to the effect that the federal statutes were not a part of the coal-land laws of Alaska and that consequently persons or associations operating in Alaska were not restricted to a single exercise of the right granted to locate coal claims and secure patents therefor. Had the ruling of the circuit court been upheld, entries of coal land in Alaska might be made by the same person or association of persons without limit as to number or even as to the time within which entries might be made.

The action of the supreme court in reversing and remanding the decision is, therefore, of great practical importance, while it also emphasizes the necessity for action by congress, which will be designed to relieve the present situation as to coal lands in Alaska.

Controller Bay Report

Reports have been filed in the so-called Controller Bay investigation which involved the conditions under which Alaskan coal lands were being held and exploited, presumably by persons who had gained the favor of President Taft's administration. The inquiry is now definitely over and the minority and majority report are before Congress. The majority report takes the view that while the investigation has developed nothing of a definite character in support of the charges made against President Taft and his administration, it has been productive of great good by assisting in preventing bad conditions from developing in Alaska. The majority report says:

"Your committee would therefore respectfully suggest that for the better development of Alaska, as well as for the general good, Congress should at an early day take action:

"(1) That will reserve to the Government in perpetuity the title to all coal land and mineral land in Alaska, the title to which has not already passed to others or in which no vested rights obtain.

"(2) That a similar course be followed as to all land containing petroleum or natural gas.

"(3) That all future land patents, deeds, or conveyances of the fee, in whatever form, shall contain provisions saving and reserving to the Government all coal, minerals, petroleum, and natural gas, on or under public lands, with the right to remove the same.

"(4) That fair and even liberal leases be made by the Government to proper parties, providing carefully for the continuous development of the lands so leased.

"(5) That a harbor and coaling station be developed for Government use and connected with one of the Alaskan coal fields by a Government-owned railroad, and we suggest Controller Bay and the Bering coal field as most convenient for that purpose.

"(6) That the Robinson bill (H. R. 13,113), now pending before the House Committee on the Public Lands, offers a satisfactory solution of the Alaskan coal-lands question, but does not cover mineral lands or petroleum or natural-gas lands, and that provision should be made for retaining the title to these also."

Alabama

Birmingham—The plan for merging the Alabama Consolidated Coal & Iron Co. and the Southern Steel Co. has been accepted, according to the official announcement of Cecil A. Grenfell, chairman of the merger committee. Mr. Grenfell declares that more than a majority of each class of securities, both of the Alabama Consolidated and the Southern Iron & Steel companies, have been deposited under the proposed plan for merging the two concerns.

The Brookside-Pratt Mining Co. will make two openings on its coal property in the near future, one at Cardiff and one at Brookside, Alabama.

The Howells Mining Co., at Blocton, Ala., on the Alabama Great Southern Ry., has abandoned its mine at this point.

The organization of a company to develop about 40,000 acres of coal land in Tuscaloosa County, Alabama, is planned by W. H. Skaggs, of Birmingham and Chicago.

Colorado

Walsenburg—The bodies of two victims of the intense cold were found here, Dec. 20. Robert Burt, superintendent of the Rocky Mountain Coal mine, who disappeared on Monday, the 18th, was found dead and half buried in a snow drift. The body of James McIntyre was found in his cabin.

Denver—The injunction which has been hanging over the heads of 2000 miners of the Northern coal fields was recently dismissed on application of the Rocky Mountain Fuel Co., so far as that company is concerned. The other companies in the Northern field did not join with the Rocky Mountain in having the case against the men dismissed. The Rocky Mountain company owns the Simpson, Vulcan and Mitchell mines at Lafayette; Gorham at Marshall, Industrial at Superior, Acme, Hecla, Rex No. 1 and Rex No. 2 at Louisville. It recently took possession of the Standard at Louisville. The mines are all in Boulder County.

Illinois

Chicago—Coal operators from practically all the bituminous producing states in the country except Pennsylvania and Ohio met in conference in the Hotel LaSalle, Dec. 18, and formed the American Federation of Coal Operators. The following officers were elected: Presi-

dent, Harry N. Taylor, Chicago; vice-president, J. C. Kolsem, Indiana.

Joliet—Miners in the northern Illinois field are enthusiastic over the preliminary lessons given them by the crew of the Government mine-rescue car. They have, as a result, formed classes at the different mines for studying the more complicated questions and phases of rescue work.

The Coal Products Co., which was recently organized, with its main office at Joliet, has increased the number of its directors from three to eleven. The company has now under construction, at a site about four miles northwest of here, a plant which will consist of 35 gas ovens of the Koppers type. Gas will be supplied to neighboring towns and the residual coke will be used for commercial purposes, there being a possibility of its qualifying as metallurgical coke.

Indiana

Bicknell—A strike of more than 500 men was inaugurated, Dec. 22, at the Tecumseh mines of the Tecumseh Coal Co., near Bicknell, as the result of the company's refusal to reinstate a machine man who had been transferred to the face to load coal because of his alleged carelessness and lack of judgment in handling the machine. The matter was referred to the arbitration board, but without avail in preventing a strike. Secretary Penna, of the Indiana Operators' Association, said: "The trouble at Tecumseh is not a small matter; there is a great principle involved. Apparently the miners are attempting to take away from us the right to protect our own machinery and our own interests."

Iowa

Oskaloosa—John P. White, president of the United Mine Workers of America, claims reëlection to the presidency by a majority of from 40,000 to 50,000 over T. L. Lewis. Mr. White bases his claim on incomplete and unofficial returns which have been received here.

Kentucky

Louisville—An organization was effected at a meeting here recently of 8 western Kentucky coal companies, operating 12 mines, under which it is planned to operate all these mines through one central company. The organization was effected chiefly by Gen. T. O. DuPont, of Wilmington, Del., who called the meeting. The tentative organization will be known as The Kentucky Fuel Co. and will have a capital stock of $1,500,000, according to present plans. When the details are completed, the merging companies will cease to exist. The 12 mines affected, lie along the main line of the Illinois Central Railroad Co., in Ohio and Muhlenberg counties, and have a total maximum output of 2,500,000 tons annually. The eight companies which are included in the agreement are as follows: W. G. Dunn Coal Co., Greenville, three mines; Central Coal and Iron Co., Central City, two mines; McHenry Coal Co., McHenry, two mines; Broadway Coal Mining Co., Simmons, one mine; Greenville Coal Co., Greenville, one mine; Nelson Creek Coal Co., Nelson, one mine; Dovey Coal Co., Dovey, one mine; the Gibraltar Coal Co., Mercer, one mine. W. G. Duncan was elected president. An agreement was reached to the effect that the proposed plans should be submitted to the various stockholders of the respective companies and a report made at a meeting to be held here Jan. 1. The organization will be incorporated under the laws of the state of Kentucky.

The Pond Creek Coal Co. with extensive holdings in Pike County, Kentucky, has completed preliminary surveying work on its properties and actual development will be started Jan. 1. A permanent organization of the company has been effected with Albert F. Holden, of Salt Lake, as president and Thomas B. Davis, Jr., of New York as vice-president and general manager.

Ashland—A syndicate of Maysville and Flemingsburg, Ky., capitalists is reported to have acquired 12,000 acres of excellent coal land in Letcher County. It is understood that 22 miles of railroad will be built from the mines to Portsmouth Blade.

Sebree—The Sebree Coal & Mining Co. has been sued for $10,500 as commissions alleged to be due for making the sale of a mine belonging to the company.

Missouri

Joplin—Coal has been discovered near the Weaver mine, about four miles north of Coal Junction in Jasper County.

Ohio

Martins Ferry—A fire at Glencoe, Dec. 20, destroyed six dwelling houses which were owned by the Pittsburg Belmont Coal Co. and occupied by miners. The loss is $5000.

Athens—The New Pittsburg mine No. 10, at Hocking, near here, closed down recently for an indefinite period, according to the officials of the company. About 500 miners are thrown out of work. The mine was closed last year from December until May.

Hamden—The Vinton-Jackson Mining Co. is making extensive preparations to open up its property at Vinton Furnace, 8 miles east of here. This property has lain dormant for a number of years. E. D. R. Sutton, of Philadelphia, with two eastern railroad contractors, is making an estimate of the probable cost of a switch from the main line of the Baltimore & Ohio Southwestern R.R. to the site of the proposed plants.

Columbus—The Grand Trunk Ry. Co. has purchased from the Rail & River Coal Co., of Pittsburg, 31,000 acres of coal land in Belmont County, Ohio, near Wheeling, W. Va., including six operating mines with a capacity of 750,000 tons of coal annually. The purpose is the shipment of the coal for use along its own lines. The capital stock of the Rail & River Coal Co. was $2,500,000, and there are $2,500,000 in bonds outstanding. It is understood that the Rail & River Coal Co. obtained about $3,00,-000 for its properties, and that the Grand Trunk Ry. Co. has guaranteed the bonds. It is said that the railway company purchased the 31,000 acres because of an impending deal to consolidate a number of mining companies in Belmont and Jefferson Counties.

Pennsylvania

Bituminous

Dubois—The new extension of the Pittsburg, Shawmut & Northern R.R. from the mouth of the Mahoning Creek to Knoxdale was officially opened for traffic, Dec. 18. The new Chickasaw mines, formerly known as the Tidal mines, were put in operation at the same time and will ship over the new road. The opening of this branch marks the completion of 28 miles of main line and a 4½-mile spur.

Connellsville—The Tip Top mine of the H. C. Frick Coke Co., near Owensdale, has been shut down and abandoned after nearly 40 years of operation. The stumps and ribs have been cleaned up and now only a little crop coal remains on the property. For the past year only 40 of the more than 100 ovens have been in use.

Reynoldsville—A fire at the Bloomington mines near Rathmel, recently destroyed the engine and boiler houses.

Lock Haven—A runaway trip of seven mine cars on the inclined plane of the Kettle Creek Coal Mining Co., near Bitumen, resulted, Dec. 16, in the instantaneous death of two men and the serious injury of two others, all of whom were riding the cars. The accident is attributed to the breaking of a shoe on the band brake of the lowering device.

Pittsburg—The Interstate Commerce Commission, by agreement with both sides, has postponed until Jan. 8 the hearing of the railroad's side in the case of the Pittsburg district coal operators against the 88-cent rate on coal to Lake ports. The original date fixed for a hearing on the side of the railroads was

Dec. 27. The postponement was made because of the desire of the commission to finish before the end of the year the hearing of the coke case from the Connellsville field, now pending.

The winter meeting of the Coal Mining Institute of America, held in this city, Dec. 19 and 20, adjourned after an interesting session at which a number of technical papers were presented and discussed. The following officers were elected for the ensuing year: President, A. W. Calloway, of Punxsutawney, Penn.; secretary-treasurer, Charles L. Fay, Wilkes-Barre, Penn.; vice-presidents, Elias Phillips, W. E. Fohl and Jesse Johnston.

An official of the H. C. Frick Coke Co. states that a number of additional ovens will be lighted by the company soon after Jan. 1, 1912, and predicts that the number of active ovens after that date will exceed the number in operation during the best part of the record year, 1907.

Manufacturers of the Mahoning and Shenango valleys have received notice that the petition for a reduction of freight rates on coal, coke and ore will not be granted. The railroads claim that the rate is as low as consistent at this time. The manufacturers will probably appeal to the Interstate Commerce Commission.

Coal operators of Pennsylvania and Ohio have refused to enter into an interstate wage agreement with the operators of Illinois. A decision was reached here Dec. 24, when the United Mine Workers of America called a meeting of the Ohio and western Pennsylvania operators in order to get them to join in an interstate agreement. The western Pennsylvania operators maintained that West Virginia had cut into their business so much by employing nonunion men that they could not afford to work under the conditions imposed on Illinois operators. The United Mine Workers of America decided to appeal to the American Federation of Labor to boycott all coal mined in West Virginia, in order to force the operators there to permit their miners to organize.

Anthracite

Scranton—The controlling interest in the New York, Ontario & Western R.R. has passed from the New York, New Haven & Hartford into the hands of the New York Central & Hudson River R.R. Co. The Ontario & Western is interested in mines near Scranton which produce about 5 per cent. of the total annual anthracite tonnage. The control of this road gives the New York Central for the first time an entrance into the anthracite field.

Wilkes-Barre—Three hundred employees of the Raub Coal Co., at Luzerne, near here, went on strike recently. No notice of the intention to strike was served upon the company, and when the men did not report at starting time an investigation was made, which showed they had well-laid plans to tie up the colliery. The men allege that the dockage boss discriminates against them and that they are unduly penalized.

At the last meeting of the Wilkes-Barre Mining Institute, two interesting papers were presented on the subject of mine haulage.

Shenandoah—Fire in the night of Dec. 22 destroyed the West Shenandoah colliery of the Philadelphia & Reading Coal & Iron Co. The colliery was one of the largest in the anthracite field and employed a great number of men and boys. The loss is estimated at $1,000,000.

The two miners who were entombed in the workings of the Packer colliery, Dec. 22, were rescued unharmed the following day from behind a fall of several hundred tons of rock.

Pottsville—The Philadelphia & Reading Coal & Iron Co. has awarded the contracts for one of two extensive stripping operations at Silver Creek, near here. It is said that these are destined to have the greatest coal output of any operations of the kind in the Schuylkill Valley.

The Beaver Valley Coal Co. has awarded the contract for a breaker, to be erected on its property in Scotch Valley, Columbia County. Work will be started at once.

Tennessee

Knoxville—A fire in No. 17 Right entry of the Cross Mountain mine, at Briceville, has proved a great obstacle in the work of rescue. The bodies of 84 men have been located, and, at last reports, all but two of these had been removed from the mine. The Federal mine rescue officials, excepting those in charge of the local crew, have left Briceville. The work of investigation has been carried on simultaneously with that of rescue and body-seeking. Both the federal and state officials have investigated conditions in the mine as they were reached and gathered data concerning the explosion. The mines of the Tennessee Coal Co. and Minersville Coal Co., near Briceville, have resumed operations, and other mines in the locality will soon start work again.

West Virginia

Wheeling—The Supreme Court of West Virginia has confirmed the decision of the lower courts in giving the Mountain Park Land Co. the right of eminent domain in West Virginia. It is also announced that the White syndicate of English capitalists has withdrawn from the fight for possession of the Cheat River, thus giving a clear field to the Kuhn interests of Pittsburg, Penn., as represented by the Mountain Park Land Co. and Pittsburg Hydro-electric Co. Power plants will be built along the Cheat River which will furnish electric power, first, to the Morgantown, W. Va., district, and, later, to the Fairmont and Clarksburg territory.

Fairmont—The Wenonah Coal & Coke Co., at Dott, W. Va., has work well under way on a second opening upon its property along the Norfolk & Western. The construction of the tipple has been started and a switch installed. Shipments will probably begin in the course of the next two months.

The recent examinations held at Grafton, Welsh and Charleston for mine foreman and fire boss, under the direction of the state mining department, were the most largely attended of any held so far. The one at Grafton, which was for this district, was tried by 118 men, and in all, the examinations were attended by 479. The papers are now in Charleston, and are being examined by the state examiners, who will announce the results before Jan. 1, 1912.

Canada

British Columbia—"Though work was resumed in the mines of the Crow's Nest Pass district of British Columbia and Alberta, only as long ago as Nov. 20, the mines, taken as a whole, are already producing between 75 and 80 per cent. of their normal output," said O. E. Whiteside, general manager of the International Coal & Coke Co., at Coleman, Alta. "Considering that the strike had lasted nearly eight months, I think it is a decidedly good record that the mines should be on so large a producing basis so soon. Plenty of labor is offering, the men seem to be willing to dig in, and the markets are in good shape. It will take the operators quite a while to catch up with the extra demand created by their long period of non-production."

The mine of the Lethbridge Collieries, Ltd., about 7 miles south of Lethbridge, has been developed and equipped during the past year. Two shafts were put down 600 ft. to the coal, a steel tipple erected, and a 1000-h.p. power plant built and equipped. About 300 men are now employed on construction work.

England

Wigan—The Cross Tetley coal pit near here was flooded Dec. 23 by a sudden inrush of water. Two hundred miners were below in the workings at the time and it was feared that many of them would lose their lives, but all were brought safely to the surface.

Germany

Dortmund—Six miners were killed Dec. 23 by a firedamp explosion in one of the pits of the Teutoburgia colliery.

Personals

E. H. Leaning has recently been appointed assistant treasurer and general manager of the reorganized Nay Aug Coal Co., of Scranton, Penn.

W. Clyde Williams has resigned as president and manager of the Camden Coal Co., Louisville, Ky., a local branch of the Monongahela Consolidated Coal & Coke Company.

Thos. Sneddon, Jr., recently of the Union Pacific Coal Co., is now assistant engineer with the Anaconda Copper Mining Co., coal department, and is stationed at Diamondville, Wyo.

James Bonnyman has resigned as vice-president of the Birmingham Coal & Iron Co., which was recently merged with the Woodward Iron Co., and has become president of the newly organized Bonnyman-Norman Coal & Iron Co., of Birmingham, Ala.

Niel Robinson, mining engineer of Charleston, W. Va., and Ed. W. Knight, chief counsel for the Virginian Ry., appeared recently before the Interstate Commerce Commission, Washington, D. C., in connection with the Pittsburg-lake freight-rate case.

Dr. J. J. Rutledge and J. T. Ryan passed through Knoxville, Dec. 22, *en route* from Briceville, Tenn., to Pittsburg. W. M. Burke, in charge of mine-rescue car No. 7, and A. R. Brown, foreman, left Briceville at the same time for Ashland, Ky., and Birmingham, Ala., respectively.

Thomas R. Henahen, state commissioner of mines for Colorado, was recently sent to the northern Colorado coal district by Governor Shafroth to make an investigation of strike conditions. Mr. Henahen has been a practical coal miner for 30 years, and has had charge of several large coal properties in Colorado.

John W. Groves, lecturer and mine-rescue demonstrator of the Tennessee Coal, Iron & R.R. Co., with six helmet men from the Pratt mines No. 1 division, and five helmet men from the No. 2 division, went to Briceville, Tenn., Dec. 12, to assist in rescue work at the Cross Mountain mine at the request of Dr. J. A. Holmes, director of the Bureau of Mines.

Thomas Graham, for several years superintendent of the Western Fuel Co.'s coal mines near Nanaimo, Vancouver, and previously superintendent of the Crow's Nest Pass Coal Co.'s Coal Creek colliery, near Fernie, East Kootenay, has been appointed chief inspector of mines for British Columbia as successor to Francis H. Shepherd, now representative of the Nanaimo district in the Canadian House of Commons. Mr. Graham is not only an experienced coal-mine superintendent, but also an active promoter of efficiency in mine-rescue work. His appointment will take effect Jan. 1, 1912.

Construction News

Louisville, Ky.—It is reported that the Pond Creek Coal Co., of Boston, Mass., will begin actual development work on its coal property in Pike County, Ky., as early as Jan. 1, 1912. A preliminary survey of the land has been completed.

The Harlan Coal Co., Harlan, Ky., is preparing to open several mines near Harlan, and will erect a power house and install conveying machinery and other equipment.

Indiana, Penn.—The Penn Mary Coal Co., of Heilwood, will in the near future extend its operations to Seldom Seen, about two miles from the present plant. Contract for grading two miles of railroad has been awarded to the Sims Co. Harry P. Dowler is superintendent.

Birmingham, Ala.—The Bryan Coal Corporation of Birmingham, which recently purchased about 800 acres of additional coal land, including a plant of 300 tons daily capacity, will invest about $50,000 in enlarging the plant and in building a new washer, with the idea of eventually attaining a daily output of 1000 tons. It is said that the company will subsequently develop 8000 acres of coal land previously purchased.

Recent Incorporations

Indianapolis, Ind.—The Lock & Key Coal Co., of Indianapolis, to lease and operate coal and shale mines. David B. Hill, president.

Louisville, Ky.—The Riverside Coal & Land Co., of Prestonburg; capital, $100,000. Incorporators: Walter S. Harkins, Joseph D. Harkins and Claude Stephens.

Maglinger Coal & Mining Co., of Owensboro; capital stock, $1000; incorporators: J. F. Maglinger, Jr., R. W. Maglinger and A. D. Westerfield.

Columbus, Ohio—The Crown Coal Co., of Wellston, Ohio; $60,000; to mine and sell coal from the Jackson district. Incorporators: Frank Chrissinger, G. L. Gugle, A. M. Goggens, C. Ims and N. M. Irwin.

Spokane, Wash.—The Palouse Coal & Oil Co., of Palouse, Wash.; capital, $500,000; to develop local coal lands. Incorporators: A. E. Sever, W. R. England, R. D. Halsey, J. C. Northrup and others.

Philadelphia, Penn.—The Columbia County Coal Co.; capital $1,000,000; to engage in mining coal. Incorporators: W. F. Miles, T. F. Taylor, G. Hauck, Philadelphia, and F. B. MacCarthy, Claymont, Penn.

Charleston, W. Va.—The Long Branch Coal Co., of Mt. Hope; capital, $50,000; to mine coal and manufacture lumber in the Fayetteville district of Fayette County. Incorporators: C. M. Lilly, T. H. Snyder, T. E. McGuire, and others, all of Mt. Hope.

New Publications

Tests of a Suction Gas Producer. By C. M. Garland and A. P. Kratz. Bulletin No. 50, University of Illinois. 92 pp., 6x9 in.; illustrated. 50c. University of Illinois, publishers.

This bulletin contains a complete and detailed account of the tests of small suction-gas producers, using anthracite coal. The tests were undertaken to obtain impartial data on the efficiency, reliability and operation of this type of generator and the results are summed up in seven valuable and important conclusions. An admirable feature of the pamphlet is the appendix. This gives in detail the forms used for recording the results of the tests and the formulas required for the necessary computations, a valuable acquisition for anyone contemplating a test of this character.

Résumé of Producer-Gas Investigations. By R. H. Fernald and C. D. Smith. 400 pp., 6x9 in.; 250 illustrations in text, 12 plates. Bulletin No. 13, Bureau of Mines.

This book is a compilation of the data that have been gathered on the subject of producer gas during the six years from 1904 to 1910 by the Geological Survey at first, and later by the Bureau of Mines. Most of the material has been published hitherto in a series of bulletins. The present volume, however, is a valuable contribution to the literature of producer gas, dealing with the subject under three general heads as follows: Gas producers and producer plants in general; investigations at St. Louis and Norfolk, and investigations at Pittsburg. Tabulated and graphical reports are given of the many and varied tests. Not the least commendable portions of the bulletin are its 20 pages of bibliography and an excellent index.

Trade Publications

The Goulds Manufacturing Co., Seneca Falls, N. Y. Bulletin No. 106. Vacuum and Stuff Pumps. 16 pp., 8x10 in., illustrated.

The Ohio Ceramic Engineering Co., Cleveland, Ohio. Folder descriptive of the Lakewood line of mine cars and contractor's equipment. 8 pp. 3½x6½ in., illustrated.

Ingersoll-Rand Co., New York. Bulletin Form No. 4108. 4 pp. 6x9 in., illustrated. Catalog descriptive of the B-104 Sergeant Rock Drill, a machine specially adapted for driving small headings, stoping or similar work requiring a light and small, but powerful machine. This drill has a 2½-in. diam. cylinder and will drill a 1 to 1½-in. diam. hole to a depth of 20 in. without change of steel. Bulletin shows duplicate parts of the drill and also gives full specifications and details.

COAL TRADE REVIEWS

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

There has been little or no change in market conditions during the past week. Reports generally state that the winter so far has been the most open for a number of years and the effect on the domestic market is being keenly felt by both the trade and operators. A slight activity due to the holiday cessation of operations, and consequent loss of output, is now evident, but the relief from this source will be only temporary.

On the Atlantic Coast supplies have greatly improved, because of the generally slack demand, although some shortage is still evident. This market has shown a slight activity due to the holidays and an advance of 25c. on anthracite has become effective at some points.

In Ohio and adjoining states the market is quiet and trade dull generally. Some price cutting has occurred, mostly on demurrage coal due to heavy overshipment. At the Hampton Roads piers unusually large tonnages are being handled. The general demand is spotty with the exception of slack, which is showing some strength.

Shipments to centers in the Middle West have fallen off considerably, which has materially improved the tone of this market. Weather conditions, however, continue adverse to an active domestic consumption, and the market remains dull and heavy with prices soft. It is reported that a number of mines have shut down in this section.

Adequate supplies are reported in the West, and on the Pacific Coast. The open winter, so far, has not interfered with transportation in the Rocky Mountain states, and no shortage is anticipated.

Boston, Mass.

The shortage of coal at Hampton Roads is expected soon to have effect here. While the tension in bituminous was halted for a few days by the mild weather, the holiday season is now on, and with further interruptions in water movement, January is likely to see some anxious days. Although proceeding quietly, shippers are still making purchases outside in order to tide over their customers, and few of the larger corporations have as much coal in sight as they would think it prudent to carry in a normal season. If we have any cold weather at all, prices are almost sure to be higher than any yet reached. The figure asked for the standard brands, f.o.b. Virginia ports, is still $2.70@2.75, and around $4@4.10 on cars Boston or Providence. Nearly all the distributors are behind on contract obligations, and it is hard to see how they can gain much ground during the next fortnight.

New York

There has been some extra activity in the trade this week, as there usually is around the holidays, due to the preparations of both the consumers and the shippers to accumulate stocks for their supplies and obligations this week. At this time of the year, railroad transportation is often tied up so badly, on account of the heavy passenger traffic, that coal and other commodities are sidetracked. This results in a shortage in this market, and both the consumers and the trade realize the importance of being well stocked at this season.

Fortunately, this year, no heavy snowstorms, such as occurred last Christmas, have been experienced, and most shippers are in a position to take care of contract obligations, which continue to be heavy. There are, however, a few who do not seem to have sufficient coal at New York tidewater to fill their orders, and these have purchased on the market, to tide them over. This demand has caused a slight increase in quotations of steam coal at New York, which now range, f.o.b. the piers, about $2.40 for West Virginias; $2.25@2.65 for ordinary Pennsylvanias, and $2.80@2.90 for the best grades.

Philadelphia, Penn.

The retail trade has gone through a rather apathetic week, due in a measure to the holidays, and also the weather, which has not been distinctly seasonable. All the predictions to the contrary, the start of this week was more like fall than winter and, as a consequence, trade has not been up to the mark.

The wholesale market still enjoys prosperity, all sizes being in demand with the exception of egg coal, which is becoming hard to handle. One of the individual operators in this market openly admitted that he was cutting the price of this size to move it off, and it is fair to assume that the others are doing the same.

If trouble should occur, there would hardly be any of this size for shipment at any price, as the stock of this coal is pretty generally cleaned up by the close of the year, and after that deliveries are to be made from the current production.

Pittsburg

Bituminous—The industrial demand for coal continues good, and retail has improved slightly. Prices are only fairly well maintained. A temporary decrease in shipments is expected for this week, as is usual after a holiday. Prices are subject to shading occasionally, being regularly quotable as follows: Nut, $1.05@1.10; mine-run, $1.10@1.15; ¾-in., $1.20@1.25; 1¼-in., $1.35@1.40; slack, 70@75c. per ton, at mine, Pittsburg district.

Connellsville Coke—There has been further contracting for furnace coke in the past week, at prices established in the early part of the buying movement. In the past two or three weeks contracts have been closed, chiefly for the year 1912, but in one or two instances for the first half only, involving between 50,000 and 75,000 tons a month, the common price being $1.60 for the half-year and $1.65 for the year, although one or two early sales, for specially desirable coke, ran up to $1.75 for the whole year, and there were one or two sales for the half-year at $1.55.

The furnaces now in blast which do not make coke of their own are consuming between 550,000 and 600,000 tons of coke a month, but more than half of this, between 300,000 and 400,000 tons, is going out on long-term contracts. There are more of these than formerly, as none expired during the past year and several fresh ones were made. In the past two months contracts for the year or half-year have been made, involving a total of perhaps 200,000 tons a month, and this leaves very little business to be closed, except with furnaces not now in blast.

A sharp scarcity of furnace coke for spot shipment developed late last week, with the result that sales of 4000 to 5000 tons were made at $1.75, with one or two small sales at $1.80, and a high price is expected to continue this week. The occasion was the demand from furnaces for extra coke to stock, against the probable interruptions in shipments this week and next on account of the strenuous manner in which the foreign labor in the coke region celebrates the holidays. We quote: Prompt furnace, $1.75@1.80; contract furnace, first half, $1.60@1.65; year 1912, $1.70@1.75; prompt foundry, $1.80@1.90; contract foundry, $2@2.25.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Dec. 16 at 318,234 tons, a decrease of 896 tons, and

shipments at 3386 cars to Pittsburg, 4931 cars to points west and 937 cars to points east, a total of 9254 cars, a decrease of 265 cars. Production last week was doubtless somewhat less, and a large decline this week is expected, but by the second week in January the output should be back to normal.

Baltimore, Md.

The buying which some of the large consumers did in order to provide stock enough to tide them over the holidays, somewhat stimulated market conditions in Baltimore during the past week, but even this new business was not sufficient to cause any undue activity in trade. What sales were made were confined to a few of the larger operating companies, as the smaller offices state that, so far as they are concerned, the demand for coal has not improved much over the preceding week.

The trade, as a whole, is awaiting further developments. The open weather conditions which have been prevailing here recently, have not had the tendency to engender any particularly hopeful feeling for the future. It has been some years since such mild December weather was experienced in these parts. What the trade is hoping for is a big drop in temperature, which will certainly bring about a much greater demand for coal than is reported at present.

During the past week, the operators also reported some inquiries for coke. This is encouraging, in view of the fact that the coke market here has been absolutely dead for months. Most of the inquiries came from the big steel mills.

Buffalo, N. Y.

The return of mild weather after only a slight turn colder has made this December about the worst the coal trade recalls. The hard-coal dealers are complaining most. Before the end of October there was a great clamor for chestnut and stove and some jobbers were so eager to get their early winter supply in that they ordered a full amount from several sources, counting on canceling the slowest responses after receiving what they wanted. Some shippers do not accept such methods and now that they are able to fill all orders they are insisting on enterprising dealers taking what they ordered.

There is about the usual strength to the bituminous market that has existed through the month, so that real winter weather ought to stiffen prices materially. Quotations remain at $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack, with Allegheny Valley about 25c. lower. Coke remains quiet at $4.25 for best Connellsville foundry and $3.50 for stock coke.

Cleveland, Ohio

There is absolutely nothing new in the coal situation in the past week, excepting the scarcity of slack coal, on which prices have advanced from 10 to 15c. in the last few days. This is owing to the fact that the weather has been so mild the domestic trade has fallen off at least 75 per cent., since people are not burning coal as the weather does not permit them to do so. The consequence is that lump coal is not being mined, hence the scarcity of slack.

The steam trade does not show any improvement, but there seems to be a belief that business will revive in that line soon after the new year. Prices on domestic, as well as steam, remain about the same as they have since winter set in. However, winter up to the present, is only in its infancy, and if we have the usual cold weather that should prevail during the months of January and February, domestic trade will certainly equalize itself, and make up for the poor business in the past months.

Columbus, Ohio

The domestic trade during the past week has been generally weak with some spots of strength showing at times, when the temperature became lower. On the whole, the market has been spotty in the extreme with the holiday rush aiding in weakening the demand for the domestic and steam grades. But prices have not suffered to any extent by the weakness and coal men generally believe that the condition is only temporary and will soon pass away with more favorable weather conditions.

There is a good demand for the fancy grades of domestic fuel and prices range from $1.85@2.35 for the especially prepared grades. Stocks in the hands of the retailers are fairly large at this time and unless the weather changes radically in the near future they are sufficient to take care of immediate wants.

Operations in Ohio fields have not been very active during the past week. The lull in the domestic trade, coupled with the approach of the holiday season, has caused a let-up in production and many of the districts are not producing more than 70 per cent. of normal for this time of the year. This is true of the strictly domestic fields more than in the Hocking Valley district and in Eastern Ohio. In the Pomeroy Bend field the production has been about as large as usual. Prevailing prices are:

Domestic lump in the Hocking Valley	$1.50
Domestic lump in the Pomery Bend district	$1.60@1.75
Three-quarter inch	1.35
Nut	1.15
Mine-run in the Hocking Valley	1.05@1.15
Mine-run in Eastern Ohio	0.95@1.05
Coarse slack	0.40@0.45
Nut, pea and slack	0.40@0.50
Fancy grades of domestic lump	1.35@1.85

Cincinnati, Ohio

The local coal market is weighed down under the same unfavorable weather conditions which have prevailed almost continuously for several weeks. Most unseasonable weather is causing an unusually light demand for domestic fuel and a large amount has accumulated on track here, so that considerable is being sold at cut prices in order to avoid demurrage charges. Since it is a case of giving it either to the railroads or to the consumers, the wholesalers are giving their customers the benefit of the situation. Not that it should be assumed that the wholesalers are afflicted with enlargement of the heart—even at this holiday season. Fuel sold to stop demurrage is not bringing a fair price, which is the case under almost any circumstances. It has almost become a settled fact in this market that the winter does not really begin until after the holidays.

Hampton Roads, Va.

Prices during the past week have been firmer, $2.70 per gross ton f.o.b. Hampton Roads being the standard. Nearly all of the selling agencies are still decidedly short of coal, and this state of affairs is sure to continue, as the production at the mines is beginning to show the usual Christmas falling-off. To make matters worse, both the Chesapeake & Ohio Ry. and the Virginian Ry. are short of motive power, and are not moving coal as it is loaded.

Dumping at the railway coal piers has been exceptionally heavy, and a large number of ships are under charter and yet to be loaded. Unusually heavy tonnages are being loaded in the United States colliers. On Dec. 20 the "Mars" was loaded at Lambert's Point and the "Hector" at Newport News. Bunker business has been exceptionally good also, 15 ships having been in for bunker coal in two days.

The coal loading on the Chesapeake & Ohio Ry. during November showed a total of 1,422,850 tons, a decrease of 9120 tons. The tonnage was divided up among the three fields as follows:

District	Daily, Tonnage Allotment	Month, Tons Loaded	Month, Tons Loaded Per Cent. of Allotment or Capacity
Kanawha	66,850	828,010	47
New River	45,750	477,330	..
Kentucky	9,400	117,510	48
Totals	122.000	1,422,850	

Louisville, Ky.

The local coal business continues to feel the effect of warm weather and the holiday season. The merchants, despite their vigorous advertising, are doing little business, but it is expected conditions will

improve after the first of the year, especially in view of the coming wage conference.

Quotations this week are as follows:

	F.o.b. Mines	F.o.b. Louisville
Best Jellico and Straight Creek Coal		
Block	$2.00	$2.95
Lump	1.85	2.80
Round	1.40	2.35
Nut and slack	0.75	1.50
Western Kentucky Coals		
Lump	1.35	1.95
Nut	1.15	1.75
Mine-run	0.90	1.50
Nut, pea and slack	0.70	1.30
Pea and slack	0.30	0.90
West Virginia Splint		
4-in. lump	1.40	2.40
3-in. lump	1.30	2.30
Mine-run	0.75	1.75

Retail Price per Ton Delivered	
Pittsburgh and Straight Creek	$3.75
Jellico	3.60
Smokeless lump	4.50
Anthracite	8.50
Western Kentucky	3.25
West Kentucky	3.50

Memphis, Tenn.

The situation in Memphis is at a standstill, owing to the extreme mild weather we are having; there is hardly a normal demand for coal throughout this district, which has a tendency to keep prices low. However, prices for the western Kentucky coals still stand at $1.50 for lump, $1.25 for mixed coal, $1.10 for nut, $1 for mine-run and screenings from 25@85c. Just at this time the screening market is up, owing to the scarcity of this grade, in addition to the slight preparation that consumers are making to take on a little surplus just prior to the holiday season.

The prices in Alabama from the Carbon Hill district are better than those from Kentucky, inasmuch as they are getting $2 for lump coal, and as much as $1.75 for their washed-nut coal, with mine-run $1.10@1.25. This coal moving through Memphis at this season of the year, always brings a good price.

The higher grades of coal, such as Jellico, Cahaba and Pittsburg, are selling for $4.75. The dealers in Memphis are all well stocked, prepared for a cold season, which they are anxiously awaiting.

Nashville, Tenn.

To say that the market in this field is completely demoralized, is but mildly expressing it. We have gone through a spell of weather in December that has been unprecedented, and instead of improving, it seems to have grown worse. Everyone is filled up with coal—in fact, quite a lot of it is in the city on demurrage.

Price is no inducement and lump coal cannot be moved at any figure. It will take two weeks of steady cold weather to put the coal business in this section in a healthy shape. Owing to these conditions, screenings have been much in demand, especially this week, because of the usual layoff of two or three days during Christmas at the mines. There are practically no screenings to be had, and a fancy price is being offered for them.

Indianapolis

There has been no perceptible change in the condition of the Indiana coal market during the past week. The trade is somewhat demoralized, owing to mild weather and a good supply of cars, which enabled the operators to overship the market.

The operators say that it is customary for a drop in the bituminous market to come at this time of the year, and that the present dullness differs from that of previous years only in the extent or severity of the winter. Except for a few weeks in November, the mild weather has dissipated the producers' hopes for a heavy business this winter.

Chicago

Recent heavy shipments have resulted in retailers, with a limited storage capacity, being fully stocked. Prices for smokeless lump and egg are about the same as those quoted a week ago. A lessening of shipments is causing the market to mend, so far as Hocking coal is concerned. The market for screenings is weaker, 55c. being the prevailing price for the lower grades. One lot of splint coal sold a few days ago at $1 a ton, instead of at the regular price of $1.50@1.60. Prices for Carterville coal are unchanged, and the same may be said of Indiana and central Illinois coals.

Coke—Prices asked for coke are: Connellsville, $4.50@4.65; Wise County, $4.50@4.65; byproduct, egg and stove, $4.95; byproduct, nut, $4.55@4.65; gas house, $4.85.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.35@2.50
Egg	2.30@2.40
Screen lump	2.10
Screenings	1.37@1.52
Springfield:	
Domestic lump	$2.07@2.32
Steam lump	1.92@1.97
Mine-run	1.82@1.87
Screenings	1.32@1.42
Clinton:	
Domestic lump	$2.12@2.27
Steam lump	2.00@2.20
Mine-run	1.82@2.02
Screenings	1.42@1.52
Pocahontas and New River:	
Mine-run	$2.95@3.05
Lump and egg	3.65@3.90

Minneapolis—St. Paul

Conditions in the Twin Cities are anything but encouraging this week, although most coal men are optimistic and are prophesying some severe winter weather after Christmas. December this year has been a record breaker for mildness. The average temperature for the month of November was far more favorable than December from the coalman's point of view. However, the average tonnage for the year 1911 will, no doubt, show up well in spite of the present conditions, and dealers are inclined to be optimistic.

The contract for furnishing the Court House in Minneapolis was awarded Dec. 19. It called for Youghiogheny screened lump at $4.60, with a guarantee of 14,800 B.t.u. This is a cut of nearly 40c. off circular price. Contract for the Minnesota State Prison showed a cut of 20c. a ton off circular. This contract called for Youghiogheny dock run and the price was $3 f.o.b. docks.

The retail trade here is not rushing, although they manage to keep all the teams they can get busy. The recent welcome snowfall has helped somewhat in making deliveries, sleds being used in suburban districts.

St. Louis, Mo.

There has been no change in the market; as a matter of fact it was a little bit worse the past week than at any time since last summer. The steam demand has practically ceased and there has been absolutely nothing doing in domestic. Several mines in the high-grade and standard fields have worked but one or two days in the past two weeks, and on those occasions it was to get out contract coal only, they having decided to place no coal on the open market. There is an indication, however, that after the first of the year business will be considerably better, for all stocks are depleted, and this applies to domestic as well as steam.

The prevailing prices are:

Franklin County	
Lump and egg	$1.25@1.40
No. 1 nut	1.2 @1.35
No. 2 nut	1.15@1.20
No. 3 nut	1.00@1.10
2-in. screenings	0.65@0.75
Carterville	
6-in. lump	$1.15@1.30
3x6-in. egg	1.15@1.30
No. 1 nut	1.05@1.15
No. 2 nut	1.00@1.05
No. 3 nut	0.90@1.00
Screenings	0.60@0.65
Mine-run	0.95@1.00
No. 1 washed	1.50@1.60
No. 2 washed	1.20@1.30
No. 3 washed	1.15@1.20
No. 4 washed	0.80@0.90
No. 5 washed	0.40@0.50
Standard	
6-in. lump	$0.90@0.95
2-in. lump	0.85@0.90
3x6-in. egg	0.75@0.80
No. 1 nut	0.70@0.75
No. 2 nut	0.60@0.65
Screenings	0.45@0.50
Mt. Olive	
6-in. lump	$1.35
3-in. lump	1.25
3x6-in. egg	1.00
No. 1 nut	$0.85@0.90
No. 2 nut	0.75@0.80
2-in. screenings	0.50@0.55

High-grade coals from the inner district, such as Trenton, are in fair demand at from $1.75@2. There is no coal coming in from the Springfield district, and shipments have ceased from the Harrisburg and Gallatin Counties. The Big Muddy mines, at Murphysboro, have practically cut out St. Louis shipments, with the exception of those on contract. A fair movement of anthracite chestnut has been coming in, but all other sizes are

moving slowly. Coke is much in demand —byproduct at $4.75, St. Louis, and gas house at $4.60.

Spokane, Wash.

The general conditions are quiet at present; as the weather is not cold the demand is small. The supply is good and can easily meet any emergency which may arise, although none is expected before spring. Mines in the Crow's Nest Pass are now up to about 80 per cent. capacity and expect soon to be back to their normal output before the strike.

Prices continue at the same level as follows:

	Wholesale	Retail
Rock Springs	$7.20	$9.00
Owl Creek	7.20	9.00
Kirby	7.20	9.00
Carney	6.70	8.50
Bearcreek	6.35	8.25
Roslyn steam	5.25	6.25
Canadian steam	5.25	6.25

Portland, Ore.

The market here is quiet because the weather continues mild. No great quantities of coal are being brought in according to reports from dealers, there being enough stock on hand to meet all demands unless extremely cold weather should set in for a prolonged period, which is not considered likely.

In the Spokane country some snow has fallen, but no low temperatures have been reported from any parts of the Pacific Northwest as yet this winter. Along the coast the weather has been mild. There is no indication of prices advancing here for a couple of weeks at least and the future will depend altogether on the weather.

Production and Transportation Statistics

Various Railroads, Rivers and Canals

Statement of coal and coke movement over different railroads, rivers and canals for October and first 10 months of the years 1910-11, in short tons:

Railroads	Month of October		Ten Months	
	1910	1911	1910	1911
Baltimore & Ohio¹	3,254,201	3,419,548	30,553,183	28,804,634

Marietta, Columbus & Cleveland Ry	7,470	1,449	82,944	22,293
Wabash Pittsburg Terminal Railway	9,193	3,555	54,916	52,025
Kanawha & Michigan Railway	....	12,947	....	85,644
Total	1,965,054	1,909,179	17,330,664	14,959,548

The Virginian Ry.

Coal and coke shipments over the Virginian Ry. for the month of November amounted to 288,577 short tons, as compared with 293,971 for October.

Exports

The following one-column table shows total exports for the first 10 months of the present year as compared with the same period last year, in long tons:

	1910	1911
Anthracite	2,483,413	3,016,127
Bituminous	9,105,787[a]	11,643,931[a]
Coke	715,196	777,861

[a]Does not include bunker or fuel coal laden on vessels which for 1910 was 5,417,517 tons and for 1911 was 5,578,497 tons.

Coastwise Shipments

Domestic shipments of coal from the five principal Atlantic ports for the first 10 months of the present year were as follows in long tons:

New York	20,563,382
Philadelphia	5,826,250
Baltimore	3,657,842
Newport News	2,212,036
Norfolk¹	3,791,794

¹Includes amount shipped by the Virginia Ry., at Sewall's Point, Va.

The Norfolk & Western Ry. Co.

The following is the current statement of coal and coke shipments over the Norfolk & Western Ry., in net tons:

Shipments	November		First 11 Months, 1911
	1910	1911	
Tidewater foreign coal	76,158	87,389	894,282
Tidewater foreign coke	3,709	8,489	70,154
Tidewater coastwise coal	230,783	303,873	2,790,824
Other domestic coal	1,216,140	1,444,053	13,950,269
Other domestic coke	172,086	118,351	1,317,997
Total	1,698,876	1,962,155	19,023,526

Foreign Markets

Great Britain

Delay of tonnage is still keeping business quiet for prompt, though operators are holding for firm figures, shipment immediately after Christmas. Approximate quotations are as follows:

Best Welsh steam coal	$4.20
Seconds	4.02
Thirds	3.78
Best dry coals	4.02
Best Monmouthshire	3.78
Seconds	3.60
Best Cardiff small coal	2.16
Seconds	1.92

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½ per cent. discount.

Japan

A certain amount of business was done on this market at the beginning of the fortnight but the revolution breaking out at Wuchang has absolutely paralyzed trade throughout the whole of the Yangtsze Valley: The uncertainty as to which side will eventually come out "on top" is too great and Native dealers and merchants of all classes and trades will not commit themselves.

The market in Japan is rather active and prices are firm, while in Shanghai prices are stationary on account of the stoppage of business.

"Link-Belt" Chain Retarding Conveyor and Shaking Screen Tipple. Length, 425 feet. Capacity, 300 Tons an Hour.

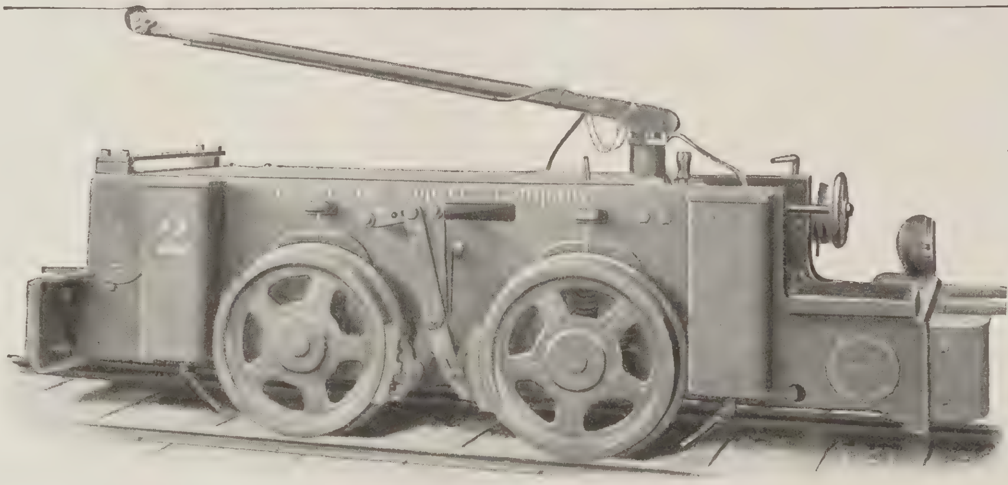
HEAD ROOM, MINERAL SPRING BREAKER - LEHIGH VALLEY COAL CO.

Baldwin-Westinghouse Electric Mine Locomotives



What they do, not What they cost.

Baldwin-Westinghouse Mine Locomotives have Baldwin Locomotive construction, which, added to Westinghouse Electrical Equipment, is a combination impossible to equal.

We now build Baldwin-Westinghouse Mine Locomotives with interpole motors. These are fundamentally the same Westinghouse Interpole Motors that are revolutionizing electric railway equipments. On a Baldwin-Westinghouse Locomotive they mean longer life of brushes, brushholders, commutators and of the locomotive as a whole, besides allowing greater overloads to be carried without injury.

It may be true that Baldwin-Westinghouse Mine Locomotives cost more. And why not? We aim to make the best locomotives, not the cheapest.

Nevertheless, mine owners find Baldwin-Westinghouse Mine Locomotives cheapest—*in the end*—they stay in service. The wise buyer disregards first cost; the ultimate cost is what he considers.

WESTINGHOUSE INTERPOLE MINE MOTOR

COAL AGE

Vol. 1 NEW YORK, JANUARY 6, 1912 No. 13

One mine manager recently took exception to a statement we made that coal mines throughout the country were operating at "such and such" per cent. of their capacity. Because a local boom had struck his camp, he thought equally favorable conditions prevailed everywhere.

So it is with many people—they think only as far as they can see, and since each one's horizon is the limit of his vision, the conclusions arrived at by an individual are often wrong because they're based entirely on a local view. For this reason, it is necessary to consult figures rather than the man when we are wanting to know the nation-wide condition of an industry.

There's no denying that every other person we meet today is complaining of slack business—sort of a depression, etc. Yet, one thousand industrial companies in 1911 paid $410,000,000 in dividends, which is $30,000,000 more than was paid in 1910 and $90,000,000 more than was paid in 1909. If that doesn't indicate a healthy growth, then we're justified in the belief that prosperity is indicated by reduced net income.

And how can we dispute that coal mining has received its fair proportion of the business advance of the age? In 1825 the United States produced 100,000 tons of coal; in 1850 it was seven million; in 1875 we mined 50 million; in 1900 the production was 270 million, and in 1911, the coal output of our country totaled approximately 500 million tons, or about 40% of the world's production.

If prices are low and general conditions unsatisfactory, let's not blame business, but more properly recognize that the trouble is within rather than without. An external application of salve on the stomach won't cure pimples on the nose; it's necessary to swallow something that will reach the spot, cure the indigestion and purify the blood.

We've heard for years that our summers are getting hotter and our winters milder, but the mercury makes a new low record for some particular day each year; most every fortnight someone discovers that electricity will furnish all needed heat as well as power, but he forgets to tell us how he's going to generate electricity without burning coal; then we are disturbed by the fellow who has a scheme to pierce the depths of the earth and furnish us heat; still consumption increases, and it's safe to conclude our children's children will be using more coal in their homes and factories than we ever dreamed could be mined.

Therefore, viewing the industry in the light of fact, what is there to be discouraged about? 'Tis true wages have steadily increased and the cost of timber and other materials essential to mining has likewise advanced to new high prices, but similar conditions have prevailed at the same time in other great businesses, and still profits in the aggregate have grown each year. The rule of success today is, "For each added charge, there must be an added improvement," so if props cost 2c. more per ton of coal output, the cutting machines at the face, the haulage, the hoist, or something must be operated to effect an offsetting economy.

One operator recently showed me a cost sheet which read: Total mining, 0.4612; other costs, 0.0401; royalty, 0.05; handling, putting on cars, etc., 0.053; total cost per ton, 0.6043c., and it's needless to say he wasn't a pessimist on the situation. His philosophy was, that the chief advantage to be derived from the application of advanced methods and the adoption of improved machinery is not so much the immediate bettering of output and lowering of costs, as to place and keep your mine in position to profit in full when the periodic boom arrives.

Don't forget that in 1904 the wail of coal men was, "How can we remedy this overproduction?" in 1905 and 1906 the plaint had changed to, "Where can we get cars and men?" The pendulum is still swinging—a new year and likely a new era have dawned. People won't wear white diamonds on their bosoms till they've plenty of black ones in the cellar. Unless a man is ready for the chance, the opportunity will do him no good.

The World's Coal Production

Special Correspondence

A brief synopsis of the latest available statistics concerning the world's production, together with notes on the different fields. The total extraction is over one billion metric tons, having a value above two billion dollars. More than six million persons are employed.

A bluebook on colonial and foreign statistics, prepared by the British chief inspector of mines, and issued by the Home Office Department, supplies what are perhaps the most complete statistics in one volume, relating to persons employed, output and accidents at mines and quarries throughout the world. The volume was issued in September and gives the statistics for 1909, but owing to the want of adequate official data the figures in some cases have merely been estimated from the records of earlier years; those for the leading coal-mining nations are, however, fairly complete.

Production

It is seen that at the mines and quarries of the world, 6,004,928 persons were employed, and of these the inspector shows that more than one-half were engaged in mining coal alone. Great Britain employed over 997,000; the United States, 660,000; Germany, 688,000; France, 190,000; Russia (1908), 174,000; Belgium, 143,000; Austria, 134,000, and India, over 119,000.

These are impressive figures, and we further learn that the coal produced was 1,113,308,386 metric tons, possessing a value estimated at nearly 400 million pounds sterling, or, say, two billion dollars. These figures show an increase in production for the year of 45 million tons but a decrease in value of 46 million dollars. The three leading coal-producing countries are the United States, with over 418 million tons; Great Britain, with over 268 million, and Germany, with over 217 million. These countries are followed by Austria-Hungary, France, Russia and Belgium, in the order given, representing the seven nations having a production of 20 million metric tons or more. Japan comes next on the list with 15,058,113 tons; India, with 12,060,550 tons; China, with 11 million tons, and Canada, with 9,526,784 tons.

Mortality Statistics

Taking the coal mines for which the figures are fairly complete, it is shown that the death rate per thousand persons employed in the United Kingdom was 1.43; the British Empire, 1.48; Austria, 1.13; Belgium, 0.95; France, 1.17; Japan, 3.51; Germany, 2.30, and for the United States, 3.35. The death rate for countries outside the British Empire generally was 2.48.

Commonwealth of Australia

The Commonwealth produced 8⅓ million metric tons of coal in 1909, nearly 86 per cent. of which was furnished by New South Wales. In this state, excluding lignite and seams of the Triassic age, it is computed that the main coal-bearing rocks extend over an area of 24,000 to 28,000 square miles around the seaport of Sydney.

As yet, Tasmania supplies less than 70,000 tons *per annum*, although there are abundant seams of marketable coal in the country. These belong to the Carboniferous and Mesozoic periods, and vary from 20 in. to 12 ft. in thickness, while brown coal and lignite occur all along the North Coast.

The state of Victoria contributed 130,230 tons. Since November, 1909, this state has owned its own coal mine on the Powlett River, the output of which to Sept. 7, 1910, was 93,431 tons, valued at the mine at $203,883. At that date coal was being raised at the rate of over 1000 tons per day and over 900 men were employed in the mine and on the various development works.

The following figures show the main sources from which the fuel supply of the world for 1909 was obtained, with the value in pounds sterling and the increases or decreases on 1906:

MAIN SOURCES OF WORLD'S FUEL SUPPLY

Country	Quantity		Value	
	Metric Tons	Increase or Decrease on 1906	Dollars	Increase or Decrease on 1906
United States	448,038,000	+40,788,000	554,503,000	+22,571,000
Great Britain	268,007,000	+2,282,000	517,187,000	—50,241,000
Germany	217,446,000	+2,159,000	413,214,000	—1,119,000
Austria-Hungary	48,813,000	—153,000	74,314,000	+1,684,000
France	37,840,000	+456,000	112,110,000	—3,197,000
Russia	24,455,000	—1,448,000	(not stated)	....
Belgium	23,518,000	—40,000	65,775,000	—8,307,000

Canada

The oldest coal fields in Canada which have been largely developed, are situated on the seaboards of the Atlantic and Pacific Oceans. On the Atlantic side of the continent, bituminous coal is being mined from thick seams of true Carboniferous age at the Sydney (Cape Breton), Picton, Inverness and Cumberland coal fields, in Nova Scotia. The coal of the Pacific Coast, generally bituminous, belongs to the Cretaceous age, and is derived from collieries at Nanaimo, Extension, and Comox in Vancouver Island. The thick seams of bituminous coal, which exist in the vicinity of the Crow's Nest Pass, are now being worked on an extensive scale, and a large quantity of the coal mined is converted into coke for use in the smelting industry in British Columbia. All these coals are of Cretaceous age.

Natal

In this colony in 1909 about 9000 persons were engaged, the coal produced being 1,815,253 metric tons, valued at $3,229,400. There were 25 electrical coal-cutters and 97 worked by compressed air in operation, nearly 62 per cent. of the coal being obtained by machine-mining—perhaps the highest percentage for any single country in the world.

New Zealand

The output here was 1,941,918 tons, valued at $5,055,000. The most important collieries are situated near Westport, on the West Coast of the Midland Island. More than one-third of the total output is brown coal or lignite, and many of the workings are open-cut. The coal from the West Coast bituminous fields is of a high class and used by the Admiralty. From the Point Elizabeth State coal mine, 207,450 tons were produced, and the amount from the Seddonville State mine was 74,180 tons during the year ended Mar. 31, 1910. The profits of both state mines during the fiscal year amounted to $23,900.

Austria-Hungary

In Austria the principal workings for brown coal are in the Brux-Dux-Teplitz and Falkenau-Elbogener basins. In the former, seams of Miocene age occur up to a thickness of 98½ ft. (30 m.), while in the latter, seams of Miocene and Oligocene* age are worked. In the Schalltal district there is a seam which in places is over 100 m. (328 ft.) in thickness.

*Abstract of report issued by the British Home Office Department.

*The Oligocene is the transitional period between the Eocene and the Miocene of the Tertiary.—Editor.

Austria produced 13,713,042 metric tons of coal in 1909, nearly one-half of which was obtained from the Upper Silesian coal basin which is a continuation of the Prussian and Russian coal field. In this basin there are numerous rich seams of excellent coking coal.

Belgium

In this country, coal mining is the most important mineral industry, and there are six different regions; the most productive is the Charleroi district, yielding about one-third of the total output. The average production per underground worker in 1909 was only 228 metric tons, due probably to the small size of the seams, which on an average are only 2 ft. 1.59 in. (65 cm.) thick. In Belgium the average daily wage per underground worker is less than a dollar a day.

German Empire

Deposits of brown coal are found in more or less abundance over nearly the whole of North Germany. The deposit of *Vorgebirge* near Cologne in the Rhine Province consists of a large, continuous bed extending about 25 km. (15½ miles) from north to south with an average width of 6 km. (5¾ miles). A preparation called *Kaumacit* has attracted some interest. It is brown coal rendered transportable and imperishable by a process of dry distillation, reducing the coal to from 35 to 50 per cent. *Kaumacit.* The process yields an additional 3 per cent. of tar, 17 to 26 lb. of ammonia, and 2500 cu.m. of gas, per load of 10 tons.

There are three principal coal-mining districts in Prussia: (1) The Lower Rhine and Westphalian Basin, by far the most important; (2) Silesia, and especially Upper Silesia; (3) the Rhenish district in the neighborhood of Saarbrucken and Aix-la-Chapelle. Most of the coal is derived from seams of the Carboniferous age; near Hanover there are extensive workings in the Wealden beds. In 1909 Germany exported 23,350,730 metric tons of coal.

Japan

The coal-bearing formations of the Japanese Islands range from Mesozoic to Tertiary. The coal, which occurs in 43 of the 49 prefectures, is mainly bituminous and most of the seams belong to the Tertiary period. The principal coal fields may be divided into five groups as follows: Kyushu, Hokkaido, Honshu (the main island), the Southern Islands and Karafuts. More than two-thirds of the total output is produced in the island of Kyushu. In 1874 the output was less than a quarter of a million tons, and in 1909 it reached over 15 millions. A large part of the coal produced in Japan goes to supply the Chinese markets.

Peru

All the different varieties of fuel exist in Peru, viz., peat, lignite, coal and anthracite. Lignite is found in the Tertiary rocks on the coast and at the summit of the Cordillera at Cajamorca. The true coal and anthracite are found in the Cretaceous rocks in various places, and a solid hydrocarbon which is neither coal nor anthracite occurs in veins, and is likewise worked and sold as mineral fuel. There are large areas of coal in the department of Ancachs, in the Santa Valley, at Jatunhuasi, near Jauja, in the department of Junin, in the neighborhood of Cerro de Pasco, and in the departments of Huanuco, Cajainarca and Libertad. The bulk of the output is obtained from the province of Cerro de Pasco.

Philippine Islands

Coal occurs in the Tertiary shales and sandstones on nearly every island, with the greatest development in the Visayas. The most promising coal fields at present are situated in the provinces of Albay, Cebu, Tayabas, Sorsogon, Mindovo and Moro. Four coal seams have been found in Cebu having thicknesses of 2, 5, 10 and 13 ft. The total output in 1909 was obtained from two mines on the island of Batan in the province of Albay.

Russia

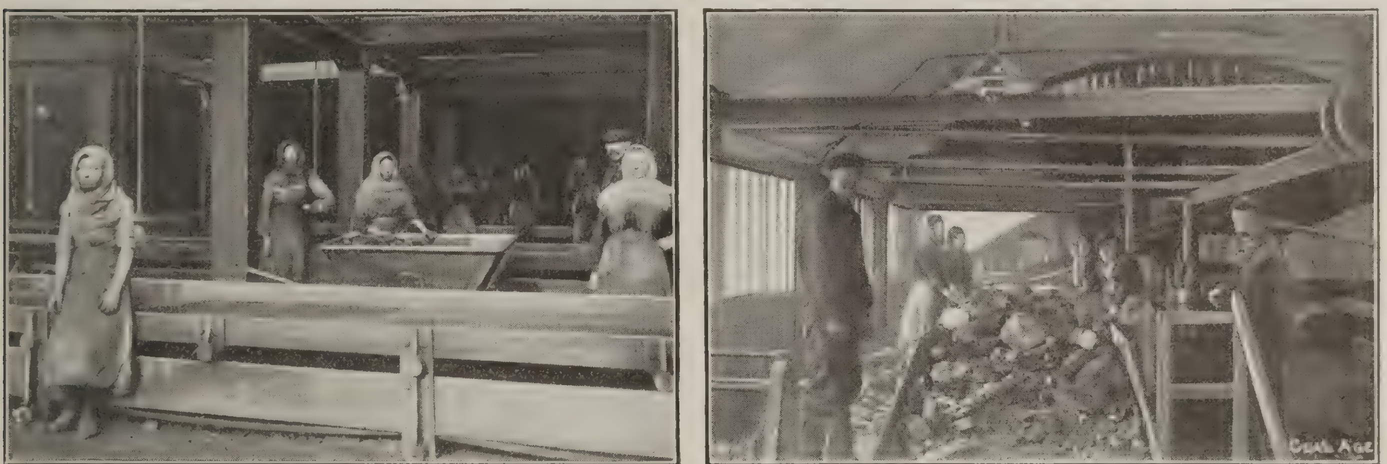
The most productive coal region of Russia is the Donets basin in the province of Ekaterinoslav, which covers an area of 16,000 square miles, the seams varying in thickness from 1 to 7 ft. The output of this basin in 1909 was 17,779,-863 metric tons. Next in importance comes Poland, with an output of over 5⅔ million metric tons of true coal and brown coal. The Dombrowa Basin, in Poland, is a continuation of the great Silesian coal basin. Coal is abundant in Siberia, both east and west, and even along the line of the Trans-Siberian Ry., but the quality is poor. In the island of Saghalien, coal is worked by Russian convicts; the present output is small and is used by steamships.

Servia

Most of the coal in Servia lies near the Danube, the workings of chief importance being at Dobra. The coal occurs in the Liassic formation, which belongs to the lower portion of the Jurassic. True coal, said to be almost as good as English coals, occurs and is worked in the Timok Valley, near Urska Tschuka. In the Boljevac district a coal basin extending over a large area has been discovered. Servia is rich in mines of brown coal and thick beds of Tertiary brown coal occur at Senje, Sisevac, Resava, Jelasnica, Koaljevac and in many other parts of the country. The revenue from the state mine at Senje in 1909 was $183,000 and the expenditure $180,000. It is explained by the Mining Department that 60 per cent. of the total production from the state mines is delivered to the Servian State Ry., and charged at their own cost price; otherwise the working of the mines would result in a large profit.

Sweden

All the Swedish coal obtained in 1909 was produced from the provinces of Malmohus and Kristianotad in the southern part of the kingdom. The seams, which are of Rhodanian age, are inter-



In Many European Mines, Girls Are Employed in the Screen Houses to Push Cars and Pick Slate

stratified with beds of fireclay, and the two minerals are worked together. The thickness of the coal seams, including the partings of shale, varies from 3 to 5 feet.

Italy

In this country the development of the deposits of fossil fuel, which mineral is stated to be abundant in the provinces of Arezzo, Pisa and Grosseto in Tuscany, is hindered by the cheapness of imported coal from the United Kingdom. The total output in 1909 was only 555,073 metric tons, of which 552,136 tons were lignite, 2055 tons anthracite and 882 tons bituminous shale. Most of the lignite came from Tuscany; the anthracite from the provinces of Cagliari (Sardinia) and Turin, and the bituminous shale from Vicenza.

Turkey

Although coal is known to occur in nearly all the provinces of the empire, the only mines deserving mention at the present time are those at Eregli. Important deposits of lignite or brown coal exist in the region of Lebanon, and near Lampsacus on the east side of the Dardanelles. Coarse lignite has been found in several places near Sparta, Karaman, and in the Bulghar Dagh which may prove useful for smelting purposes. Coal deposits are known to exist in the Van district in the province of Erzeroum.

Summary

The tabulated statement in the next column shows the separate outputs, in 1909, of the various coal-producing countries of the world, as given in the report of the British Home Office. The figures for Brazil, China, Korea and Mexico are estimated from those of the previous year, and, in the case of Peru, Romania and Bulgaria, the totals given are for 1908.

It will be noted that the United States, with an output of 418 million tons in 1909, produced something over 37½ per cent. of the world's coal for that year, or 1½ times the amount mined by Great Britain and 1.9 times that produced by Germany, the two countries ranking second and third, respectively, in point of individual output. The annual production of coal in the United States has since increased by nearly 75 million tons.

WORLD'S PRODUCTION OF COAL

Country	Metric Tons
Great Britain and Ireland	268,007,257
Australia	8,316,452
British Borneo	127,944
Canada	9,516,784
Cape Colony	93,695
India	12,060,550
Natal (including Zululand)	1,815,253

Total for the world	1,113,308,386

Coal Mine Mortality Statistics

By Frederick L. Hoffman*

Carefully compiled and accurate statistical data on the death rate in North American mines. The rates are computed on the basis of the number of men employed, and show an almost continual advance, being especially rapid during the past decade.

*Statistician, Prudential Insurance Co., Newark, N. J.

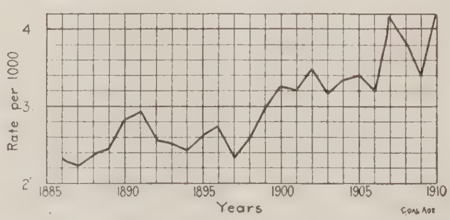
The production of 514,392,000 short tons of anthracite and bituminous coal during 1910 involved the loss of 3051 lives in 21 states and provinces of the United States and Canada. The loss of life exceeded that for the corresponding period in 1909, when, according to the corrected returns, there were 2417 fatalities. The actual excess of deaths during 1910 over 1909, was, therefore, 634, showing an increase of 26.23 per cent.

The fatality rate for 1910 was 4.18 per 1000 persons employed, against 3.39 for 1909. The fatality rate for 1910 was therefore, 0.79 per 1000 higher than during the preceding year, an excess equivalent to 23.3 per cent. The rate for 1910 was the highest on record during the last decade, the nearest approach thereto having been 1907, when the rate was 4.15 per 1000.

Bureau of Mines Contradicted

This comparison of the record for 1910 with 1909 is upon the basis of the official returns furnished by the mine inspectors of the different states. The facts derived from trustworthy sources, therefore, contradict the statement made in the program of the National Mine Safety Demonstration under the auspices of the U. S. Department of Mines that:

> The coöperation of inspectors, miners, mine owners and the Bureau of Mines in the effort to reduce loss of life has resulted in a decrease of 25 per cent. in fatal accidents in 1908 and 1909, the last two years for which figures are available, and with continued earnest coöperation it is hoped that the succeeding years will show a still further lessening in loss of life, and a corresponding increase in efficiency in mining methods and mineral utilization.



Increase in Mortality Rate 1886-1910

It is true, of course, that the rates during 1908 and 1909 were lower than during 1907, when the rate was materially increased by a number of disasters of exceptional magnitude. The decrease, however, did not justify the assumption that the reduction was the result of the coöperation of inspectors, miners, mine owners and the Bureau of Mines, except in certain well defined and strictly limited directions, which do not require to be considered at this time. The chief object for calling attention to the glaring inconsistencies of the statement referred to, and the facts which are a matter of official record, is to emphasize the lamentable truth that whatever has been done during recent years to bring about a reduction in the fatality rate does not justify the belief that measurable results of material importance have been thus far secured.

As is well known, the year 1907 was an exceptionally disastrous one in American mining. A comparison of 1908 and 1909 with the record of 1907 is obviously misleading when it is assumed that the lower fatality rate during these two years was brought about by deliberate measures for accident prevention. Comparing 1908 with 1907, there was an actual reduction in the number of accidents equivalent to 22 per cent., and comparing 1909 with 1907, there was a reduction of 23 per cent. But comparing 1909 with 1908, the actual number of accidents was almost the same, and the reduction in the rate, making allowance, of course, for the number employed, was only 12 per cent.

Comparing the record for the last two years with every other year in the history of American mining except 1907, the actual loss of life has been greater, and the corresponding fatality rate has been in excess of the rate for any other year. The record for the two years, 1908 and 1909, is not one to be proud of, or to be referred to as showing evidence of a material reduction in the loss of life as the result of deliberate efforts or coöperation between existing agencies for that purpose. The loss was exceedingly high actually and relatively, and the details do not furnish proof of a perceptible influence as the result of the agencies referred to in the quotation.

Comparison of Roof Fall and Explosion Fatalities

It is true that, comparing 1909 with 1908, there was a decrease in the number of deaths due to gas or dust explosions. This decrease was from 396 to 341, but it may have been purely accidental and not the result of the coöperative efforts referred to. As a matter of fact, in the fatal accidents due to powder explosions, missed shots, etc. (which are particularly subject to reduction by education, improved methods of shot firing and handling of explosives), there was an increase from 73 in 1908 to 108 during 1909.

We may, therefore, take the two groups of causes, which are especially related to the present-day efforts toward accident reduction. According to the official statistics, as published by the U. S. Geological Survey, there were 469 deaths from these two groups of causes during 1908 against 449 in 1909, or an actual reduction of 20 deaths, equivalent to only 4.26 per cent. The corresponding facts for 1910 are not as yet available.

Far more significant than the foregoing comparison is the fact that, while in 1908 there were 1080 deaths due to falls of roof or coal, the number of deaths from this group of causes during 1909 was 1191. So the actual reduction in fatal accidents due to explosions, etc., during 1909, as compared with 1908, was only 20, or 4.3 per cent., while there was on the other hand an actual increase in the deaths from falls of roof of 111, equivalent to 10.3 per cent. It requires to be said that there was a reduction in the miscellaneous causes. This may or may not have a relation to the efforts to reduce casualties in mining; only the detailed analysis could bring out the facts.

Fatalities during 1901 to 1910

The number of persons killed by accidents in the coal mines of North America during the decade ending with 1910, is shown in detail in Table I. The table has been corrected for previous years and is, therefore, not strictly comparable with the table published in the *Engineering and Mining Journal* for Dec. 31, 1910. Such corrections are inevitable in the present state of mine inspection and the methods which prevail in giving publicity to the facts.

All tabulations of this kind are impaired by the lack of precise definitions of terms. What is considered a fatal accident in one state is not necessarily

(TABLE I)

considered as such in another. A uniform definition of a fatal accident on the part of all the mining bureaus is desirable. It should not be difficult to come to an understanding on this point and secure, if necessary, the required changes in the mining laws of the several states. It would seem a reasonable compromise to insist that all mine accidents terminating in death within one week after their occurrence should be returned as fatal, since a longer period would involve many uncertainties which would tend to further impair the accuracy of the results.

During 1910 there occurred 3051 fatal accidents in the coal-mining operations of North America, against 2417 during the previous year. In the aggregate there have been 22,638 fatal accidents in coal mining during the decade ending with 1910, or an average of 2264 a year. West Virginia with 320, and Colorado with 319.

Fatality Rate per 1000 during 1901 to 1910

Table II shows the fatal accident rate in coal-mining in the United States and Canada, calculated in the usual manner, upon the basis of the average number of persons employed in mining operations. For certain purposes it would perhaps be more useful to calculate the fatality rates upon the basis of the average number employed underground, but since this would require a separation of underground and outside fatalities, an element of uncertainty would be introduced in the calculations which is eliminated by the use of the returns as a whole.*

During 1910 the fatality rate was 4.18 per 1000 against an average rate of 3.56 for the decade. The highest previous rate occurred in 1907, when it reached 4.15 per 1000, and the lowest rate occurred in 1903, when it was 3.16. Even the minimum rate is decidedly above the average fatality rate of foreign countries, which, during the ten years ending with 1908, was only 1.53 per 1000.

During 1910 the highest rate prevailed in Colorado, where it attained to the extraordinary proportion of 21.6 per 1000. The only higher rates reported for any one state and year of the decade under review were for British Columbia, 25.67 for 1901 and 34.65 for 1902; and for Tennessee, 25.8 for 1902. Next to the State of Colorado the highest rate during 1910 is reported for Alabama, where it attained 10.81 per 1000. Other states with rates above the average for the year were: Illinois, with 5.44; New Mexico, with 4.89; Oklahoma, with 5.43; Utah, with 4.38; Washington, with 7.15; and West Virginia, with 5 per 1000. The lowest rate for the year was reported for Missouri, or only 1.55 per 1000. The states with the next lowest rates were: Iowa, where the rate was 2.17; Kansas, with 2.26; Indiana, with 2.41; and Michigan, with 2.43.

The highest average fatality rate for the decade ending with 1910 was for the province of British Columbia, or 9.21 per 1000, followed by the State of Colorado, with an average of 8.39. The lowest averages were reported for Missouri, where the rate was only 1.48 per 1000, followed by Iowa, with a rate of 2.09.

(TABLE III)

FATAL ACCIDENTS IN THE COAL MINES OF NORTH AMERICA

COMPARISON OF 1910 WITH THE FIVE PREVIOUS YEARS

	Number of persons killed Yearly Average		Rate per 1000 Employed		Increase or Decrease of Rate
	1905-1909	1910	1905-1909	1910	
Alabama	134	238	7.09	10.81	+ 3.72
Colorado	81	319	6.33	21.60	+15.27
Illinois	183	406	2.76	5.44	+ 2.68
Indiana	45	51	2.39	2.41	+ 0.02
Iowa	32	39	1.87	2.17	+ 0.30
Kansas	37	25	3.18	2.26	— 0.92
Kentucky	35	84	2.03	3.97	+ 1.94
Maryland	13	17	2.17	2.93	+ 0.76
Michigan	7	6	2.44	2.43	— 0.01
Missouri	13	16	1.52	1.55	+ 0.03
Montana	14	13	4.75	3.16	— 1.59
New Mexico	19	14	6.71	4.89	— 1.82
Ohio	124	162	2.63	3.32	+ 0.69
Oklahoma	36	46	3.93	5.43	+ 1.50
Penn., anthracite	631	601	3.72	3.57	— 0.15
Penn., bituminous	568	539	3.20	2.79	— 0.41
Tennessee	32	38	2.86	3.40	+ 0.54
Utah	9	15	3.79	4.38	+ 0.59
Washington	27	43	4.94	7.15	+ 2.21
West Virginia	362	320	6.44	5.00	— 1.44
British Columbia	27	28	4.79	3.61	— 1.18
Nova Scotia	31	31	2.58	2.82	+ 0.24
Average	2,461	3,051	3.60	4.18	+ 0.58

(TABLE IV)

TWENTY-FIVE YEAR RECORD OF THE FATAL ACCIDENTS IN THE COAL MINES OF NORTH AMERICA 1886-1910

	Number of Employees	Number Killed	Rate per 1000 Employed
1886	222,029	514	2.32
1887	230,834	514	2.23
1888	278,175	659	2.37
1889	278,361	681	2.45
1890	301,295	873	2.83
1891	326,684	959	2.94
1892	343,564	883	2.57
1893	384,249	970	2.52
1894	394,146	962	2.44
1895	404,553	1,061	2.62
1896	409,320	1,123	2.74
1897	409,830	956	2.33
1898	407,536	1,056	2.59
1899	421,489	1,250	2.97
1900	464,235	1,507	3.25
1901	494,287	1,586	3.21
1902	530,624	1,849	3.48
1903	576,365	1,820	3.16
1904	609,001	2,027	3.33
1905	643,225	2,186	3.40
1906	658,880	2,106	3.20
1907	686,460	2,852	4.15
1908	715,355	2,744	3.84
1909	712,550	2,417	3.39
1910	730,707	3,051	4.18
1886-1890	1,310,694	3,221	2.46
1891-1895	1,853,196	4,835	2.61
1896-1900	2,112,410	5,892	2.79
1901-1905	2,853,502	9.468	3.32
1906-1910	3,503,952	13,170	3.76
1886-1910	11,633,754	36,586	3.14

These totals do not exactly correspond to the figures published by the Bureau of Mines, since for certain states, in the present tabulation, the returns are by fiscal years and not by calendar years. The recommendation frequently made, that the returns should all be for calendar years, may be repeated, for unless the returns are made on a monthly basis it will be impossible to secure an accurate and complete annual tabulation.

It is a significant fact that, during 1910, the number of reported fatal accidents in the twenty-one states and provinces is, for the first time in our mining history, in excess of three thousand. The highest previous records had been for 1907, when there were 2852, and 1908, when there were 2744 deaths. On the basis of actual numbers, the loss of life was greatest in the Pennsylvania anthracite region, where 601 deaths occurred, followed by the bituminous region of Pennsylvania with 539, Illinois with 406,

Rate for 1910 Compared with the Previous Five Years

Table III exhibits the fatal accidents in coal mining in 1910, compared with the average for the preceding five years, both upon the basis of actual numbers and the rates per 1000 employed. Many of the states and provinces show an increase in the rate during 1910 over the average for the preceding five years, the exceptions being Kansas, Michigan, Montana, New Mexico, Pennsylvania (anthracite and bituminous), West Virginia and British Columbia.

The net increase in the rate during 1910 was 0.58 per 1000 over the average rate for the five years ending with 1909. The record shows that the rate increased in 13 out of the 21 states and provinces, but this increase was largely the result of a few disasters of exceptional magnitude. However, the record for nearly all of the states and provinces is not one

*For an extended discussion of fatal accidents in coal mining, by occupation, nativity, causes, etc., see Bulletin No. 90 of the Bureau of Labor, Washington, D. C., 1910.

which warrants the assurance that material progress is being made in the reduction of the preventable loss of life in coal-mining operations in the United States and Canada.

STATISTICS FROM 1886 TO 1910

Table IV affords a means of convenient comparison of the fatality rate in coal mining during 1910 with the corresponding rates for the previous 24 years. The quarter-century review is extremely interesting and peculiarly suggestive, in view of the unwarranted assertions that the rates during the last few years have considerably declined, due to the intelligent coöperation of government and state officials, mine managers, miners and others interested in the subject.

The accompanying profile shows graphically the fluctuations in and gradual increase of the death rate during this period. It will be noticed that the low rate in 1887 of 2.23 per 1000 has never since been even closely approached, with the exception of 1897, when it dropped to 2.33. Immediately after this the profile shows a rapid and uniform increase, crossing the 3 per 1000 line for the first time in 1900, since which date it has never been below this point. The comparatively level line during the period 1900 to 1905 may have given rise to false hopes, which were, however, quickly dispelled by the most abrupt and erratic fluctuations yet in evidence, during the period 1905-1910. During this time the rate has twice crossed the 4 per 1000 line, and the general average has been higher than for any previous existing record.

The total number of lives lost, as far as reported, during the 25 years ending with 1910, was 36,586. If allowance is made for accidents not reported, and for the small mining states not included in the present review, it is safe to assume that during the last 25 years not less than 40,000 lives have been lost in coal-mining operations in the United States and Canada.

American vs. English Mine Fatalities

By J. T. Beard

Conditions affecting death rate peculiar to American mines. Two methods of estimating death rate. Estimation on a tonnage basis more nearly approximates what death rate should show. Pennsylvania death rates, 1908-1910, lower than those of Great Britain. Output per man double that in England.

Numerous comparisons have been made, from time to time, during the past few years, of the fatalities of coal mining in this and other countries. These comparisons have, in many instances, shown a comparatively high death rate in the United States. In other instances, in spite of the modifying influences that operate to increase the death rate here, a comparatively lower rate of fatality has been shown.

Briefly stated, some of the more important influences at work in this country and which all will admit are peculiar to the United States, are as follows: the large influx of foreign labor seeking employment in any capacity; the unprecedented demand for coal, incident to a new and rapidly growing country of large area and resources; the rapid development of the coal industry in the United States within less than half a century. Other conditions might be mentioned that imperil our mining and require the most thoughtful consideration on the part of all, in order to reduce the list of fatalities in mines to a standard that will comport with our aims and aspirations as a nation.

For the purpose of this article, however, the conditions named—influx of foreign labor; demand for coal; and rapid development of mines—are sufficient. We desire to be fair and make no unjust claims for ourselves; but we feel, rightly, that much has been spoken and written, in this regard, tending to cast unwarranted reflections on American mine management.

American institutions have always embodied the highest ideals, sought out the widest knowledge and experience, and studied to adopt the most approved methods. American mine management has supplemented its own careful study of mining conditions here and elsewhere by calling to its aid mining men of other countries, hoping to glean from their observations in our mines some enlightenment on the questions mining men, the world over, are studying today. Some have sharply criticized this action as undignified and productive of no practical good, inasmuch as conditions in American mines differ widely, not only from conditions prevalent in foreign mines, but in mines in different parts of our own country.

The study of conditions must ever be supreme in the solution of all important mining problems. The broadest and most capable minds will always study closely not only the conditions of their own environment, but that of others. History is the only sure interpreter of the future when the application of past experience to present conditions is made intelligently. To consult others and study their experience does not imply that the student or inquirer has no experience of his own, or that such experience is any less valuable than that of others. It rather shows wisdom and intelligent foresight with a desire to improve.

But to return to the question of comparative death rates in mining, it has long seemed to me that the manner of estimating the fatalities per 1000 men employed is not an equitable basis. It would seem that in order to make a full and equitable comparison of the fatalities incurred in mining, the estimation should be based on the number of men employed in the mine, the number of hours employed, and the degree of danger, which varies, being different in different mines, and for which the mine management is in no way responsible.

A little reflection will make clear the injustice of classifying in the same category a mine in which 350 inside men are putting out 1000 tons of coal each working day, with another where twice that number of men produce but 800 or 900 tons a day. At once the question is asked: "Wherein lies the difference; are not these mines equally dangerous?" According to the present accepted basis, the mine last named, employing more men and producing less coal, would show a lower death rate on the number-of-employees basis, but a higher death rate on a tonnage basis, for the same number of fatalities, than the first mine where fewer men put out more coal.

It will be generally conceded that, for the same efficiency of mine management, the number of fatalities may naturally be expected to depend on three principal factors; namely, number of men in mine, number of hours worked, and degree of danger to which the men are commonly exposed in the particular mine in question. The number of fatalities would increase with the number of men and hours of employment and the danger. The last named factor—the particular danger of the mine—though dependent on physical conditions that are impossible to forecast, may be gaged more or less correctly by the output per man per hour, varying inversely as such unit output or tonnage. The hours of employment will evidently vary as the tonnage of the mine and inversely as the number of men, or as the tonnage per man.

Writing these factors out, or expressing their relation algebraically, they reduce as follows:

$$\textit{Fatalities vary as } (\textit{men}) \times (\textit{hours}) \times (\textit{danger})$$

$$\textit{Hours vary as } \frac{\textit{tonnage of mine}}{\textit{men employed}}$$

$$\textit{Danger varies inversely as } \frac{\textit{tonnage of mine}}{\textit{men} \times \textit{hours}}$$

or

$$\textit{Danger varies directly as } \frac{\textit{men} \times \textit{hours}}{\textit{tonnage}} = \frac{\textit{men}}{\textit{tonnage}} \times \frac{\textit{tonnage}}{\textit{men}}.$$

Hence,

$$\textit{Fatalities vary as } (\textit{men}) \left(\frac{\textit{tonnage}}{\textit{men}}\right) \times 1 = \textit{tonnage}$$

If the foregoing analysis can be taken as representing with a fair degree of approximation the relative number of fatalities that may justly be expected in mines operated under various physical conditions beyond the control of the management, it would follow that the degree of efficiency with which the mines are managed would be properly represented on a tonnage basis. In other words, the death rate should then be expressed as the ratio of the number of fatalities to the tonnage of the mine, and not to the men employed. This seems to me a more fair basis of comparison.

The following table is interesting as showing the production, number of men employed inside and outside the mine, total number of fatalities, and the death rate, per 1000 men employed below and above ground and per 1,000,000 tons of coal mined, besides the average annual output per man in the mine, for the past three years, 1908-1910, inclusive, in the anthracite and the bituminous mines of Pennsylvania, as compared with the same data in the mines of Great Britain, as compiled from the mining report of the Department of Mines of Pennsylvania, 1910.

Referring to this table it is interesting to note the large average annual output per man in the Pennsylvania mines, both anthracite and bituminous, as compared with that of English mines, the former being practically double the latter. This item alone serves to emphasize the urgency of the demand for coal in American mines, or the tendency of the miner to increase his tonnage, as it cannot be assumed that any physical condition operates in both the hard- and soft-coal mines here to increase the average output per man so as to make it double that in English mines.

It is also interesting to note, after what we have remarked in reference to the true basis for estimating the death rate in mines, that, in the table, the English death rate per 1000 men employed is lower, for each year, than the corresponding rate for the same respective years in Pennsylvania. On the other hand, the English death rate per million tons of coal mined is higher, year by year, than the corresponding rates in the American mines. The question naturally is suggested, which of these is the proper rating as indicating the relative efficiency of the mine management; for that is what we expect the death rate to show.

TABLE SHOWING PRODUCTION OF COAL, NUMBER OF MEN EMPLOYED, FATALITIES AND DEATH RATES, AND AVERAGE ANNUAL OUTPUT PER MAN 1908–1910, INCLUSIVE, PENN. ANTHRACITE, PENN. BITUMINOUS AND GREAT BRITAIN

Year	Production (tons)	Employees: Inside	Employees: Outside	Employees: Total	Total Fatalities	Death Rate: Per 1000 Men	Death Rate: Per 1,000,000 Tons of Coal	Average Annual Output per Man (Tons)
	Pennsylvania Anthracite							
1908.....	83,543,243	124,233	50,270	174,503	678	3.88	8.12	672
1909.....	80,223,833	123,272	47,923	171,195	567	3.31	7.07	651
1910.....	83,683,994	121,542	46,633	168,175	601	3.57	7.18	689
	Pennsylvania Bituminous							
1908.....	114,937,375	152,536	29,304	181,840	572	3.15	4.98	753
1909.....	136,205,695	152,424	33,497	185,921	506	2.72	3.72	893
1910.....	148,770,858	159,671	33,817	193,488	539	2.78	3.63	932
	Great Britain							
1908.....	261,512,214	796,329	191,484	987,813	1,306	1.32	5.01	329
1909.....	263,758,562	818,381	195,617	1,013,998	1,453	1.44	5.51	323
1910.....	264,292,588	848,381	201,026	1,049,407	1,769	1.68	6.69	314

Taking the tonnage basis as the proper method of estimation, which I believe is a nearer approximation to what it is desired to show, the death rates for these years are lower in the American than in English mines. It will be observed also that the death rate, on this basis, has uniformly decreased in Pennsylvania during this period, year by year, while in English mines the rate for the same years shows a uniform increase.

Electric cables for mine use should be incased in iron pipes or well tarred wooden troughs. All jointing should be most carefully done or serious accidents resulting in loss of life may follow. Wrap all joints with tape and ram in with bitumen. In gaseous mines all electrical machinery should be inclosed so as to be flame-proof.

Leased and Owned Coal Lands

A preliminary statement of the statistics of tenure of coal lands by operators in the United States for the year 1909 was recently issued by Director Durand of the Bureau of the Census of the Department of Commerce and Labor.

In regard to these statistics, it should be noted that they cover the holdings of none but coal-mine operators, and for these operators include no acreage but that of mineral lands, that is, other acreage held by operators, some of which may or may not contain coal, and the surveyed lands of nonoperators are not included in these figures. The total number of acres controlled and the total anthracite holdings of the United States and of Pennsylvania are exclusive of 10,975 acres of anthracite coal land sublet by operators to each other and reported twice.

It is significant that the only increase in the acreage of anthracite lands has been made in the division of lands owned by the operator, while the number of acres of land developed under lease has decreased. This is explained by the fact that the larger producers of anthracite bought large areas of coal lands several years ago to hold as reserve supplies. Since royalty must be paid continuously on coal land held under lease, whether coal is mined or not, the leased lands are not conserved, but are mined out steadily. This, in part, accounts for the decrease in the acreage of anthracite lands held under lease, and it is in part accounted for by some occasional purchases of leases by large operators, thereby changing the form of tenure from held under lease to owned property. The increase in the number of acres of mineral land reported as owned is due not only to lands acquired, but also in part to the classification as mineral lands of lands previously held by large producers, but not determined as coal-producing areas.

COAL LANDS OWNED AND LEASED BY OPERATORS IN PRINCIPAL COAL-PRODUCING STATES DURING 1909

	Acres Controlled	Acres Owned	Acres Held Under Lease
United States.	(1) 6,906,088	4,782,170	2,134,893
Anthracite..	(1) 274,870	183,144	102,701
Bituminous.	6,631,218	4,599,026	2,032,192
Pennsylvania.	(1) 1,927,829	1,509,425	429,379
Anthracite..	(1) 274,010	183,044	101,941
Bituminous.	1,653,819	1,326,381	327,438
West Virginia.	1,147,527	590,885	556,642

Indiana......	141,272	104,938	36,334

(1) Exclusive of 10,975 acres of anthracite lands reported twice in totals for acres owned and acres held under lease.

Reviews of Coal Industry for 1911

Reports from state mine inspectors, special correspondents and others with estimates of the year's production and outlook for 1912.

The coal industry during the year now closed is remarkable rather for what did not occur, than because of any new features developed. No important departures in the science of mining or in mining appliances have been made, nor has the country been visited by such an extended series of holocausts as caused a veritable reign of terror in several previous years. That it has met with many troubles and disappointments cannot be denied, but it has acquired confidence in meeting and overcoming these and has gathered new strength.

In common with a number of recent years, 1911 witnessed further consolidations of corporate interests in which the coal industry figured prominently. The economies possible to effect by such consolidation are fully appreciated by capital and the ensuing years will no doubt bring forth larger and stronger combinations along these lines. An entirely new development, in this direction, has been the organization of a National Coal Operators' Association, only yet in its infancy.

In production, this year has been a good one, since the output has nearly equaled that of 1910, but this, unfortunately, does not bespeak an entirely satisfactory business, because of the low coal prices that prevailed. It is true also that general industrial conditions are all below normal, and the heavy tonnages, thrown on an already weakened market, have produced a condition bordering on demoralization. With the productive capacity of our mines far in excess of the average normal consumption, such conditions will continue to prevail until some system of regulation is inaugurated, and it is such problems as these that have made necessary the operators' organization.

The export shipments for the year show an unprecedented increase which is, however, hardly normal because largely due to the labor troubles in British Columbia. That the United States is forging to the front as a fuel exporter is becoming clearly evident, and that this may eventually become an outlet for our over-production seems reasonable to believe.

Labor troubles during the year of 1911 have amounted to practically nothing. During the present year, however, the industry will face the most important wage conference in the history of the country, when the present agreements all expire simultaneously April 1.

The present year will inherit some of the problems of the old one, and no doubt develop new ones of its own, but the confidence gained in overcoming the difficulties of 1911 will do much to engender a spirit of optimism in the coal industry.

Coal Industry of Alabama in 1911

SPECIAL CORRESPONDENCE

The production for the year 1910 was 16,139,228 tons, but is not expected to go so high in the present year, the chief mine inspector estimating it at about 14,500,000 tons.

The labor supply has been fair all year, with the exception of a temporary shortage toward the latter part of the summer when mines which had been closed down were started up and other mines put in more regular operation. The year has been free from strikes or other disturbances of like nature.

The production of coal was low during the spring and early summer as the market conditions were not as good as during that period of 1910, for during that year, strikes in the coal fields of Illinois and Oklahoma helped conditions here greatly. Also furnace requirements have not been as large this year as in 1910.

In regard to the labor supply, it should be said that as far as actual numbers on the rolls are concerned, there is little or no difficulty. We have usually had a sufficient number of men enrolled to operate our plants, but many of these are inefficient workmen, who work so irregularly that it is impossible to rely on them. Mining is rendered hazardous by the employment of a shifting force of men, and profits are curtailed when the daily output is liable to be reduced by the unforeseen absence of some of the men.

Colorado Coal Industry in 1911

BY JAMES DALRYMPLE*

The coal business in Colorado for the year 1911 has not been quite so lucrative as it was in 1910, although the output has been normal and satisfactory, all things considered.

The larger production of last year was due to the demand from markets which were affected by the miners on strike in Illinois, Kansas, Arkansas and Oklahoma; the needed supply being drawn from the Colorado fields.

Then, too, the adverse financial condition and business lethargy of the entire country have had considerable bearing on the coal industry. The disturbed industrial condition in Boulder and Weld counties where lignite is mined has continued uninterruptedly since last year, with no prospect of an immediate settlement. Otherwise coal production has been steady and found a brisk market. Prices have advanced from 25 to 50c. per ton on domestic coals.

Operators have had to cope with the usual shortage of cars in the last four months of the year, which always hampers the production materially and retards the meeting of the market's demands. The working force for 1911, which was 13,813, shows a reduction of 955 men, as compared with 1910, when 14,768 men were employed. There is a decrease in the tonnage of coal produced during 1911 of 2,029,026 tons.

*Inspector of coal mines, Denver, Colo.

The death rate is low, being 6 per 1000, which compares favorably with other years in Colorado. The nonfatal accidents number 248, as compared with 146 in 1910. Surface fatal accidents numbered six, and underground fatal accidents totaled 82.

A dust explosion, augmented by powder, occurred at the Cokedale mine, owned by the Carbon Coal & Coke Co., of Las Animas County, on February 9, 1911, in which seventeen lives were lost. This was the only catastrophe during the year.

The mining laws of Colorado are faulty, but after the Governor appointed a commission to amend and improve the present laws, which commission worked faithfully for five months, the Governor felt it incumbent upon him to veto the bill, as it was mutilated beyond all recognition.

The following is a summary of the coal production in Colorado in 1911:

SUMMARY OF THE COAL PRODUCTION OF COLORADO IN 1911

Number of mines in operation	158
Tons of lignite coal produced	1,676,975
Tons of semibituminous coal produced	761,526
Tons of bituminous coal produced	7,502,981
Tons of anthracite coal produced	64,379
Tons of unclassified coal produced, estimated	70,000
Total number of tons produced	10,075,861
Decrease in 1911	2,029,026
Total number of tons of coke produced	946,284
Total number of coke ovens in operation	2,764
Total number of employees in and about the mines	13,813.3
Total number of days worked	188.7

The Illinois Coal Industry in 1911

Special Correspondence

The fiscal year which ended June 30, 1911, showed only 53 counties producing coal in Illinois as against 55 in the previous year. The number of mines and openings had also reduced from 881 to 845, a drop of 36 mines. In the fiscal year 184 mines were newly opened or reworked, but in the same time 217 were closed or abandoned. Though there was a slight reduction in mines working, the whole tonnage produced rose from 48,717,853 tons in 1910 to 50,165,099 in 1911 or 2.97 per cent. There was a reduction of only 3 shipping mines in 1911.

Of the mines operating 458 engaged in local trade only. There were 33 less of these mines operating in 1911 than in the year before, the tonnage from them declining from 1,492,652 to 1,406,442. The total tonnage shipped in railroad cars was 44,578,400 tons as against 43,007,015 tons in 1910, but this gain was not equal through the range of sizes. Thus the amount of mine run gained largely. In 1910 only 10,220,456 tons were shipped; in 1911 the tonnage was 13,025,663 tons. There was consequently a loss in many of the sizes of screened coal. Lump coal declined from 20,769,930 to 19,588,409; nut, from 2,845,693 to 2,425,712 tons; slack, from 1,372,038 to 1,131,784. On the other hand, two sizes much shipped from Illinois mines showed increased use. Egg mounted from 3,334,059 tons to 3,725,073 tons, and pea coal similarly from 10,174,677 to 10,268,458.

The locomotive tender trade as supplied to the tenders at the mines fell with the decreased railroad business from 886,217 tons to 877,793 tons. The local trade also fell from 2,867,871 to 2,617,977 tons. There were consumed or wasted at the plants 2,090,929 tons whereas in 1910 the amount reported aggregated only 1,956,750 tons. The average operating days of shipping mines declined from 179 to 169 and all mines, shipping and domestic averaged only 165 days of work as against 171 days on the previous year.

Price Little Changed by Wage Increase

The price per ton rose from an average of $1.016 to $1.101, or $0.085. The gross selling value at tipple totalled $56,064,494 as against $50,204,207, an increase of 11.7 per cent. Motor haulage took a further advance. There are now 316 motors used, whereas in 1910 there were but 229, a significant increase of 38 per cent. Mining machines were used in 126 mines, whereas in 1910 there were 114 mines in which they were to be found. The mining machines accordingly increased in number from 1289 to 1430. The number of tons undercut by machines was 19,998,259, whereas in 1910 it was 18,176,254 tons. In 1911 the number of tons hand-mined declined from 30,541,599 tons to 30,166,840 tons.

Men Employed

In 1911 the miners employed numbered 39,912, having increased since 1910, when the number was only 39,069. In Illinois the number of other employees underground is large. In 1911, 30,052 persons other than miners worked in the mines and the number increased more than the number of miners. In 1910 there were but 28,137 not actually engaged in the mining of coal. The number of boys working underground dropped from 1154 to 1009. Above ground the boys employed rose from 47 to 71. The number of other employees above ground in 1911 was 6366; in the previous year there were 6227 of such operatives. The total number of employees above and underground increased from 74,634 to 77,410 persons. Thus the employees may be divided up as follows roughly: Miners, 51.6 per cent.; other underground adult employees, 38.8 per cent.; boys underground, 1.3 per cent.; boys above ground, 0.1 per cent.; adult employees above ground, 8.2 per cent.; total, 100 per cent.

Of the whole number of adult employees, 74,508 were employed at shipping mines in 1911, and 71,520 in 1910. The local mines employed 2902 in the last fiscal year. In 1910, 3114 men were thus employed. There were 70,973 working below ground in 1911 and in the year before, 68,360 were thus employed. The corresponding number for workers above ground in the coal mining industry of the state were 6437 and 6274.

Mining Rates and Consumption of Powder

The average rate for hand-pick mining in the shipping mines per gross ton was $0.627, an increase over the year before of three cents. Machine mining also cost 3.2 cents more, the price so advanced averaging $0.494 per gross ton.

The number of kegs of powder used for coal blasting was 1,240,293; in 1910 1,254,095. Powder was used for other purposes to the extent of 3568 kegs last year; in the previous years, the use reached 3128 kegs. Permissible explosives were used to the extent of 243,099 lb.

Fatalities and Injuries Not Decreasing

The Cherry mine disaster was so abnormally severe that it does not seem well to include it in making comparisons between the two last years. That disaster is omitted therefore from the 1910 calculations. Last year 157 men were accidentally killed, 7 men more than in the previous year. Of these 149 men were killed inside and 8 outside the mines. The deaths made 87 wives, widows, and left 245 children, fatherless. Injuries entailing the loss of a month or more totalled 709. In the previous year such accidents were more numerous, 742 men being so incapacitated. There were 319,523 tons mined for every life lost. In 1910 the record was a trifle more favorable, 324,786 tons. The number of employees per life lost was 493, whereas in 1910 the number was 498, so that if it had not been for the Cherry mine disaster, 1910 would have had a little better record than the past year.

For convenience in figuring, it may be well to add that deaths per thousand men employed ran 2.03 in 1911, and 2.01 in 1910, with the reservation referred to. In 1911, 70,754 tons were mined for every man severely injured and in 1910 only 65,657 were produced at the same loss and suffering. Out of every 109 men last year one man was injured. In 1910 that proportion was only 101 to 1. The number killed for each million tons produced was 3.1 in both the years considered. The number injured for every thousand men employed was 9.9 in 1910 and 9.2 in 1911. It will be observed that the figures for tonnage, activity and injuries, fatal and otherwise, are not materially changed. The compensation to labor has increased 5 per cent. for hand-pick work and about 6 per cent. for machine work.

The increase in the price of coal is probably due to the conditions obtaining after the strike and that price may decline in the following fiscal year. It will be seen that the operator made an increased gain of about 5c. on an increased product of 2.97 per cent.; not such a bad record for the year 1911, which has not appeared bright in other states. Moreover, improved haulage methods and increased machine mining should have added largely to that profit.

Note—From report of State Mining Board.

Indiana Coal Industry in 1911

By Frank I. Pearce*

Beginning with January, and slightly before, the demand for coal became less brisk and many of the mines that had been operating nearly full time, previous to and for a considerable time after the settlement of the strike in Illinois, were unable to work more than half time during January, February and March.

With the approach of milder weather, market demands grew weaker, competition stronger and selling prices took a drop. As a result of this condition many mines that had been working about half time were unable to operate more than one or two days a week and a number were closed down indefinitely, or to make repairs.

This condition continued through April, May, June, July, August and the first half of September resulting in considerable suffering among hundreds of idle employees depending upon the mines for their livelihood, and in many instances a considerable outlay of money to the companies to keep their mines in repair. Even where this was done property in many instances suffered a certain depreciation in value, that is, a fixed loss.

Demand for Coal Improved

The latter part of September the demand for coal began to improve somewhat and from this period until Dec. 15 the mines averaged about half time, and a number that were closed down earlier in the year resumed operations. Market conditions grew a little stronger and selling prices advanced.

The coal production of any state is governed by the demand, number of days worked and number of persons employed. The demand for coal has been poor for the year 1911 as compared with 1910 resulting in a greater loss of time, a larger number of employees being idle, and the production proportionately reduced.

*Deputy Inspector of Mines, Indianapolis, Ind.

Production

The condition of the coal trade being somewhat similar to that of the year 1909 the production will be about the same, or possibly 14 million short tons, slightly in excess of what it was that year. However, this is only an estimate as the state's production has not yet been compiled for the year.

There were a number of strikes during the year but most of these occurred at a time when the demand for coal was such as to not seriously affect the state's output.

Coal Industry in Iowa

By L. E. Stamm*

In reviewing the coal industry of this state for the year just drawing to a close I am pleased to note that the conditions for the most part have been good and that the tonnage has reached the highest mark in production since coal mining first began in this state during 1840. In recent years the annual coal production of Iowa has increased steadily, except in the years 1908 and 1910, when a slight falling off in the production was noted, caused possibly by a suspension of the mines for a period of thirty days during each of those years, pending an agreement between the miners and operators relative to a wage agreement.

Largest Tonnage Ever Produced

Under the laws of the state of Iowa, statistics relating to the production of coal in the state are gathered for the fiscal year ending June 30. These statistics gathered for the last fiscal year show a production of coal amounting to 7,574,919 tons. This is the largest tonnage ever produced in this state, and while these are figures for the fiscal year, it would be safe to say that they will approximate those for the calendar year. In the production of the tonnage noted above, 16,571 persons, both miners and others, were employed in and around the mines, and the work of mining was fairly good during most of the year. The coal industry of Iowa, while not of such magnitude as in a number of states, still has much to do with the general prosperity of the state.

Coal was first discovered and mined in Iowa in 1840, and at that time was mined in but one other state west of the Mississippi river. Only 400 tons were produced in 1840, while in 1857 the production had reached 1,231,547 tons. In 1882 it had reached 3,920,000 tons, while for the year 1899 more than 5,000,000 tons of coal were mined. Since then the output has steadily increased. As stated above, the tonnage for the fiscal year of 1911 was 7,574,919 tons.

Coal Mined in 22 Counties

Coal is mined in 22 counties in Iowa. The product is bituminous and of good quality. Some coal is shipped from this state into Nebraska, Minnesota and the Dakotas, but most of the coal produced is consumed within the borders of the state. Its manufacturing industries provide a market for most of the coal produced in Iowa, and on account of the absence of friction between the miners and operators of the state the coal industry has made a steady growth. Owing to the mild weather which has prevailed in Iowa from September onward, the coal production has not been quite so good as is usually the case at this time of year, but with the coming of cold weather we look for a steady demand for coal; one that will keep the mines of the state running on a fairly steady basis.

*Secy. to Mine Inspectors, Des Moines, Iowa.

Owing to the extension of the Rock Island System from Des Moines south, a new coal field will be developed in Marion County during the coming year. Already the Rock Island company is starting the development of a new mine near Dallas, Marion County, and this mine will be equipped for a daily capacity of two thousand tons or more. Other mines will be developed in this section, so the outlook for the year 1912 seems at this writing to be bright for an increased coal production. However, the coming April marks the time for a new agreement between the operators and miners of the state and, judging from past years, there is likely to be a suspension of mining for thirty days or more at that time. This will affect the output for the coming year to some extent.

But Few Labor Troubles

There have been but few labor troubles affecting the production of coal in Iowa during the past year. A few local strikes have occurred, caused by a difference of opinion as to the terms of agreement between the operators and miners. For the most part these disagreements or strikes were of short duration, and did not affect the coal output to any great extent. Judging from past years, it would seem at this time that there will be an increase in the coal production of this state in 1912.

Coal Production of Kansas 1911

By Leon Besson*

The coal production for the year 1911 will be approximately six million tons. It will be greater for the year 1911, than it was for the previous year, owing to the fact that in the year 1910 there was a long suspension of work, extending from April 1 to Sept. 22. On the other hand there have been few local labor troubles in the present year, and these not of any importance. An average of about 11,500 men were employed in the mines of the state. There have been a few mine explosions this year, causing the death of five shot-firers and two rescuers. I am of the opinion that the coal production will be steadily on the increase, for there is a tendency to go back to coal, as natural gas seems to be approaching exhaustion.

Maryland Coal Statistics for 1911

By J. H. Donahue†

From all the available data at hand, it appears that the coal production of Maryland for the year just closed will show an appreciable falling off. The production for 1911 as estimated, will be 4,500,000 short tons, as compared with nearly 5,000,000 tons in 1910 and 4,524,112 tons for 1909.

*State mine inspector, Pittsburg, Kans.

†Chief Mine Inspector, Frostburg, Md.

Maryland was particularly fortunate during the past year with respect to labor troubles, having experienced no inconvenience from this source whatever. It is estimated that the average days worked will be about 240, and the number of fatal accidents during the year will not total more than 15. The non-fatal accidents have not yet been reported.

North Dakota Lignite in 1911

By J. A. Bliss*

During the year 1911 there were ninety-eight coal mines in operation in North Dakota, producing about 395,000 tons of lignite. Over a thousand men were employed during the busy season which begins in October and closes in January. During the summer months the demand for lignite falls off, and as a result part of the mines are closed down. North Dakota mines are entirely free from explosive gases, and the list of fatalities and injuries has been low during the past year.

The demand for lignite is gradually increasing and several new mines have been opened up, while some of the larger operating mines have added to their equipment. Although the estimated amount of lignite within the state exceeds that of any other state in the Union, the demand for it is largely of a local nature, and because of its abundance the selling price is so low that the margin of profit is small.

The question of timbering the mines is a serious one, as dependence has to be placed on timber shipped in from Minnesota, largely, though some is obtained from the Western states.

The state legislature has wisely seen fit to lend active support to the furthering of its lignite industry, and all public institutions are required to use coal mined within the state. An appropriation has been set aside for the purpose of establishing and maintaining an experiment station. This has been located at Hebron, where a mine has been purchased by the state and an excellently equipped building erected. This station is under the direction of the State School of Mines at Grand Forks, and its efforts are largely directed toward perfecting the briquetting process and of making commercial use of the volatile gases which run high in all lignite.

The successful development of a process of briquetting on a commercial basis and of making use of the volatile gases for illumination, heat and power would create at once a demand for lignite and open a large field for investment.

The recent advent of several new branches of railroad in the western part of the state has made accessible a new portion of the coal fields, and a greater gain in production is anticipated for the ensuing year than heretofore.

*Asst. Mine Inspector, Bismarck, N. D.

Montana Coal Industry in 1911

By J. B. McDermott*

The capacity of Montana's mines has been materially increased during the year now closed. The first coal dust explosion in the history of the state occurred and important laws, governing the operation of mines, were enacted.

*State Coal Mine Inspector, Helena, Mont.

Montana is the third largest state in the Union and contains more square miles area, than New York, New Jersey, New Hampshire, Maine, Massachusetts, Maryland, Rhode Island, Connecticut, Delaware and Vermont combined. It is underlain with coal, ranging in quality from lignite to sub-bituminous, semi-anthracite and anthracite; the latter has not been found in workable quantities.

Production for 1911

Legislative action, in creating the county of Musselshell out of portions of Fergus, Meagher and Yellowstone Counties, has not decreased the production of coal, but Fergus and Yellowstone are, for a time, reduced from large producers by the change of county lines.

The following is the production by counties in short tons for year ending Oct. 31, 1911:

PRODUCTION BY COUNTIES

	Tons
Carbon	1,226,783
Cascade	948,823
Mussellshell	643,648
Park	54,760
Choteau	14,127
Gallatin	10,801
Fergus	6,670
Custer	5,044
Valley	2,741
Total	2,913,397

The new county of Musselshell, includes the rapidly growing camps, Roundup and Klein. This county is now the third largest producer in Montana.

There has been an apparent dullness in the Montana coal trade during the year just closed due to a heavy increase of capacity and consequent overproduction. At Stockett, in Cascade County, the Great Northern Ry. Co., coal department, have installed independent haulage engines for each of their new Nos. 5 and 6 mines. The Northern Pacific Ry. Co., at Red Lodge, in Carbon County, have, under their new management, increased their output from 1500 tons per day to 5000 and have even reached as high as 6000 tons. In Musselshell County, the Republic Coal Co. have increased the capacity of their No. 2 mine at Klein from 1500 tons, the record last year, to 2000, now their average daily run; this mine is now sufficiently developed to produce 3000 tons in 8 hours. In this same county, at Mine A, of the Roundup Coal Mining Company (subsidiary of the Chicago, Milwaukee & Puget Sound Ry. Co., at Roundup, the production is now 1500 tons per day. Mine B of the Davis Coal Co. is producing from 500 to 700 tons per day. Mines in the Bearcreek district are also doing considerable development in anticipation of a heavy future output.

Dust Explosion

The first dust explosion in the history of the Montana coal industry occurred on Apr. 15, 1911, at the No. 2 mine of the

Republic Coal Co., Klein, Musselshell County.

The coal seam here is between 5 ft. 9 in. and 6 ft. thick, has a hard sandrock roof, and the coal is friable and frozen to both the roof and bottom. An average analysis of the coal is: Moisture 12.7 per cent.; volatile combustible, 28.7 per cent.; fixed carbon, 50.9 per cent. and ash, 7.7 per cent.

Mining is paid for on the mine-run basis and is mined by shooting off the solid, tamping being done with fine coal and slack. The mine generally is wet, although dry in places, and fuses are used in both wet and dry holes. Shooting is restricted generally, although not entirely, to the periods between shifts.

The trouble occurred in a series of five rooms, in three of which there had been no crosscuts driven. From the testimony offered, there appears to have been about 50 in. of black powder fired at practically the same time in these five rooms. In the No. 3 room one shot had been laid parallel to the face of the room and pointed toward the left-hand rib, and another on the right-hand rib, parallel with the room pillar, and directly opposite the mouth of the other hole. It appeared that both holes were overcharged and the result was that windy shots occurred.

After the explosion No. 3 room was the only one which could not be entered until some provision was made for removing the smoke and gases. The flame burned the sight-strings in front of all five rooms, and also scorched brattice cloth on the entry further out, traveling against the intake air current some 500 ft. Fortunately, the brattice between the intake and the return (a board-stopping) gave way which short-circuited the flame into the return airway where conditions for propagation were less favorable.

No one was seriously hurt, although some where scorched slightly. The property damage was practically nothing, although this cannot be credited to good judgment or management. At present all the miners use their own discretion as to the placing of their holes, the number, and the amount of powder to use. Will we, like many other mining states, require the usual disaster and consequent loss of life, to force us into the adoption of safe laws for the blasting of coal?

Labor troubles in Canada proved of considerable help to Montana operators during their usually dull season in the spring and summer. Some coal was also shipped into Canada later in the season.

Accidents in 1911

During the year just closed there have been 13 fatal and 50 non-fatal accidents in the Montana coal mines, as follows:

TABLE OF MINE ACCIDENTS

Causes of accidents	Killed	Injured	Total
Falling roof	6	11	17;
Falling coal	2	12	14;
Moving cars	5	15	20;
Powder burned and blasted	0	5	5;
All other causes	0	7	7;

OCCUPATIONS OF VICTIMS

Occupation	Killed	Injured	Total
Pick miner	12	31	43;
Driver	1	9	10;
All others	0	10	10;

During 1911 the Montana State Legislature enacted a law providing a fund for the relief of miners injured in coal-mine accidents. The law required all operators to contribute one cent per ton of gross tonnage mined toward the support of this fund. Due to the fact that the miner, besides deriving the benefits from this fund, also retained privilege of bringing action at law for additional damages the act was declared unconstitutional by the Supreme Court of the State.

The growing sentiment in favor of some form of compensation for the dependents of those injured or killed in mine accidents, has made desirable the enactment of some such law, and it is with regret that we record its failure. From the inquiries received, applications for copies and comments made upon this law, together with words of commendation spoken at different institute meetings I have attended in Scranton, Chicago and Charleston, W. Va., I feel that this law would have come nearer filling the bill than any previous efforts along this line.

In common with all new departures, the law met with opposition from both operators and miners, which was, I think, due to a misunderstanding of its purposes. The funds were to be handled by the State Auditor, who, on proof of death or total disability, was required to make payment of $3,000; loss of eye, arm, leg, etc., was compensated for proportionately.

Examination of Mine Officials

Since the law requiring the examination of mine foremen and firebosses became effective (in the year of 1909) there has been issued 62 certificates. Twenty-six of these were issued without examination to parties presenting like certificates issued by competent authorities in other states. Forty-five were given service certificates without examination for having served continuously in the capacity as foreman for one year prior to the enactment of the law.

Prior to the meeting of the twelfth session (1911) of the Montana State Legislature, the operators and miners, at a joint meeting, agreed upon what laws they wished enacted. They were passed as presented and have now become a part of our statutes.

It is interesting to note that fully 20 per cent. of the coal produced in Montana during 1910 was mined on a royalty basis. The prices varied from 5 to 25c. per ton. In some of the Western States, as for instance Colorado, large revenues are obtained from this source. During the last two years Colorado has derived $50,000 annually from approximately 18,000 acres.

Review of Coal Trade in Ohio

The coal trade in Ohio during 1911 was not as active in many ways as that of the previous year which was the best in the history of the Buckeye State. Advance reports from the several mining districts indicate that there will be a decrease of from three and a half to four million tons in the year's production as compared to that of 1910. In some of the districts the loss was only slight and may even be turned to an increase but other districts have to report a suspension of from four to six months.

While there was a decrease in the tonnage mined, the most important feature of the coal trade was the unsatisfactory and unremunerative prices which prevailed during the greater part of the past twelve months. Prices as a whole were unsatisfactory and did not respond to the influence of weather as much as in former years. The large tonnage of 34,424,951 in 1910 was partially caused by the long lay-off in Illinois and the increased demand for lake tonnage. Taking it all in all the tonnage of about 31,000,000 in 1911 was not a bad output and if it had not been for the low prices that prevailed would have been fairly profitable to the operators.

Domestic Grades

During the year, prices did not advance above the $1.50 mark for domestic grades excepting in rare instances. Of course, the prices in the Pomeroy Bend district were higher because of the differential in freight rates but in that district $1.75 @ 1.85 was the highest point reached. Generally speaking the circular figure remained at about $1.50 during the entire time but this was not well maintained during the late winter and early spring months. The year opened with prices rather firm (somewhere about the $1.50 mark) but they remained at that point only a short time.

Under the influences of warm weather and poor steam trade, prices slumped soon after the first of the year and it was not until the middle of July that they were again pretty well maintained at the circular quotations. The stocking period produced considerable business for a short time and then followed another period of inaction during the fall months although prices did not slump to any great extent.

During the winter period weather conditions were not at all satisfactory. Up

until Christmas there was no cold weather to cause a flurry in the trade with the possible exception of one week. It has been a sort of a hit and miss proposition during the greater part of the year and will continue to be so unless conditions change to a radical degree. The Chicago market has not been such as to absorb any great amount of coal and this has had the effect of causing congestion in the domestic trade.

Retail Business

Retail business has not been as active as formerly. Dealers stocked up considerably early in the fall and the first run of orders was fairly satisfactory. Second purchases were not as numerous as usual and this caused the dealers to cancel their orders with the operators and jobbers. Good roads in the country districts of the state have had the effect of steadying the retail trade because farmers are enabled to haul coal at almost any time during the winter and consequently need not buy in large quantities in the fall.

The steam trade has been rather quiet. Requisitions on the part of manufacturing establishments were not as large as usual and business conditions in manufacturing circles have not been the best. There was a falling off in fuel requirements for iron and steel plants and also in fact in many other lines. However, prices on steam business have probably been more satisfactory than in any other branch of the trade and renewals of contracts have been made at about the same figures that have prevailed for some time.

In the department of railroad fuel the worst situation is seen. Railroad consumption fell off hundreds of thousands of tons from previous years. One large producing company reported a drop of over 400,000 tons in railroad fuel alone. Neither have prices for railroad fuel been satisfactory, as one large contract was taken at 85 cents, an extremely low figure.

Lake Trade

The lake trade was fairly active although a number of things interferred with an increased activity in that direction. The slack ore movement caused a falling off in lake shipments early in the season, which had opened auspiciously. This feature had the effect of making the boat supply rather short and later a freeze-up in the early fall caused many boats to put in for the winter sooner than usual. But on the whole the tonnage was rather satisfactory even if the prices were not the best. Congestion on the docks of the upper lake ports also interfered with a free lake movement.

In the fine-coal market peculiar conditions prevailed. The removal of demurrage charges on track storage cars permitted Ohio operators to hold up the prices to a considerable extent. The lowest price of the year was probably 30c. and the average was above that figure. The active lake season caused a large production of the small sizes.

The outlook for 1912 is not particularly promising. The one great uncertainty is the renewal of the wage scale which expires April 1, 1912. Business conditions generally are not bright and the tonnage will probably remain comparatively small.

The Ohio Coal Industry for 1911

By George Harrison*

The year's production will fall several million tons short of that for 1910. A substantial decrease is reported in the number of fatal accidents. The new state mining laws are in successful and satisfactory operation.

According to advance reports from the various coal-mining districts of Ohio for the year just ended, the production in this state will be materially reduced as compared with that for the year 1910, which reached a total of 34,424,951 tons, the greatest amount ever recorded in the history of the state mining department.

While there are no official figures at hand on which to base a correct estimate, it is believed the year's tonnage will show a decrease of from 3½ to 4 million tons. Although the loss may not be so great as at present indicated, it is true that in many districts work was unusually light during the year, while in others there was a suspension amounting to from 5½ to 6 months. Several causes led to the large tonnage in 1910 that will not obtain for this year, notably the long strike in the state of Illinois and the suspensions in other districts; also, the increased demand for lake shipments.

District Output

The tonnage of the Hocking Valley district as a whole, will fall off about 15 per cent. as compared with 1910, and that of eastern Ohio will probably show a loss of 10 per cent., or a total decrease of about 1,000,000 tons. The loss in Jackson County will be about 40 per cent.; in Meigs County, the same; in Mahoning County, 10 per cent.; Columbiana County, 20 per cent.; and in Tuscarawas County the decrease in tonnage will amount to about 200,000 tons, this being due to the enforced idleness of from 5½ to 6 months on account of the 1910-1911 strike.

*Chief mine inspector, Columbus, Ohio.

Labor and Working Time

No shortage of labor has been noted during the year; in fact, it will probably develop that the number of men employed was smaller than during the year 1910. While the decrease in the number of employees may not be particularly evident, the average working time per man will be seen to have been perceptibly reduced, with a consequent loss in earnings. The larger coal-producing counties will show no appreciable loss in the time worked, although the splendid record for the year 1910 will by no means be equaled. Other counties will show the working time as being about two-thirds and in some cases only one-half of that for the previous year, while in the districts of smallest production, the working time will scarcely reach half of that for 1910.

Prices for Ohio coal during the year were not particularly high and were subject to considerable fluctuation. A shortage of cars was reported on the Toledo & Ohio Central Ry. in the Hocking Valley. This is, however, usually the case during the latter months of the year when there is an increased demand for fuel. The lake trade for the year, it is believed, will not compare favorably with that for 1910, when the greatest tonnage ever shipped to the Lakes was recorded.

Accidents

The number of fatal accidents in Ohio will show a great decrease as compared with the preceding year. In 1910, 161 accidents were recorded, while up until Dec. 15, only 107 accidents have been reported for this year. Of this number 81 were due to falls of roofs; 10 to falls of coal; 7 to mine cars; and 3 to electricity. Particularly gratifying is the notable decrease in the number of persons killed by mine cars, from 19 in 1910 to 7 in 1911; also the decrease from 97 to 81 in the number killed by falls of roofs, and from 7 to 3 in the number killed by electric shock. So far no fatal accidents have been reported from the use of mining machines since the new law has required that the machines shall be properly shielded and has imposed a fine as penalty for removing such shields.

Belmont County reported the greatest number of fatal accidents, 36 in all, of which 32 were due to falls of roof; Jefferson County reported 21, of which 16 were due to the same cause. In these two counties the No. 8 seam of coal is

worked. This seam has a dangerous top, and in many instances the miners become careless and neglect to take it down; the result is seen in the large number of deaths from this cause. Guernsey County reported 16 killed, 10 deaths being due to falls of roofs. Three other counties each reported only two fatal accidents. Seven counties had but one fatality apiece, and thirteen counties reported no accidents at all which resulted fatally.

Violations of Mining Laws

The number of violations of the mining laws shows a decrease from 52 cases in 1910 to 37 in 1911. This latter number includes two prosecutions which were not reported to the state mine inspector's office last year until after the year's record had been closed; it also covers one case carried to a higher court and disposed of during the year. So far as it is possible to learn, all the prosecutions instituted both by the state mining department and employers of labor, have resulted in convictions. These results seem particularly favorable in view of the fact that the new code did not go into effect until June, 1910, and it required some considerable time for all persons connected with the mining industry to familiarize themselves with its provisions and the penalties for non-compliance. On the whole, operators and miners alike show a commendable disposition to respect the laws.

Prosecutions Were Undertaken

The fines for violations of the state mining law amounted to $400 and prosecutions were undertaken for the following causes: Burning impure oil, 10; employment of a minor, 1; violation of the breakthrough law, 5; not properly shielding a mining machine, 2; crossing a danger signal placed by a fireboss, 2; entering a mine before it was examined by a fireboss, 2; entering a mine generating firedamp, with an open light before mine was examined by a fireboss, 1; failure to supply sufficient ventilation, 1; failure to provide safety catches on a mine cage, 1; using acetylene lamps, 2; failure to supply proper timber to miners, 2; riding on haulage trips, 6; and selling inferior oil, 1.

Outlook for Year 1912 not Promising

The outlook for the year 1912 is not considered to be particularly promising, and it is not expected that any material improvement of conditions will be shown over the present year. One reason for this is the expiring wage contract, which will have to be considered and renewed. Nevertheless there seems to be no reason why 1912 should not be a reasonably prosperous year for both employer and employee.

The Coal Industry of Oklahoma, 1911

By Ed. Boyle*

Suspension of work, competition and other influences have combined to restrict the year's production in Oklahoma to less than half what it normally should be in view of existing developments. The coke industry is at a standstill. Accidents are gratifyingly few.

Oklahoma's coal deposits are extensive, but the state has labored for many years under serious difficulties in connection with the production of her natural resources. The coal-mining industry has been retarded for a number of reasons, and the first among these is the fact that practically all the mines of the state are worked under lease from the Federal Government. For several years past the Interior department has refused to lease any coal land in the belt segregated by the U. S. Government, and consequently there have been no new developments in the Oklahoma field, except such as have taken place on an extremely small scale, where coal has been discovered on the lands allotted to the Indians. These lands have, in some cases, been leased by individuals or small companies, and, in the aggregate, have added materially to the total output.

Mining Cost and Competition

The coal in Oklahoma outcrops on the prairies with a pitch of from 5 to 45 deg. The seams are usually worked by slopes in the vein and where development was started a number of years ago these slopes have, in many instances, now reached such a depth that mining has become much more expensive than it was when carried on closer to the surface. Along with this condition, coal production has been retarded by the competition of cheaper fuels, such as oil and natural gas, of which there seem to be inexhaustible supplies in this state. The only system by which Oklahoma coal can be put on the market at a price to meet the competition from adjoining coal fields and other fuel supplies, involves sinking shafts to reach the vein which is being worked at present. These shafts would, in many instances, have to run down to a depth of 500 or 600 ft., and, under present conditions, the coal operators do not feel disposed to undertake any measures which will require so large an outlay of money or capital as would thus be involved.

Coke Industry

There are a number of seams of coal in Oklahoma, varying in thickness from 24 to 72 in., which are of exceedingly good quality. Some of this coal makes an excellent grade of coke and a large number of ovens have been built in this field. At one time large quantities of coke were supplied to the smelters of Mexico, but this trade has been lost on account of the prohibitive duty, since imposed by the Mexican government. It has been found unprofitable here to attempt to manufacture coke in competition with the Colorado field for furnishing this grade of fuel to smelters throughout the West, and, therefore, the coke ovens of Oklahoma now stand idle almost without exception.

The total coal production of Oklahoma for the year 1911 will reach approximately 2,800,000 tons, which is an extremely small output for this field. If there was a market for the coal, the present openings and development should be producing, with steady work, 6,000,000 tons per year, but it seems that during a suspension of work in 1910, the operators lost most of their contracts to competitive fields and have been unable to regain them up to this time.

Wasteful Methods

The system of mining in general use in Oklahoma is criminally wasteful. Leases have usually been secured with but one object in view, which is that of getting out the cheapest coal and leaving the balance to go to waste. It is now time that the people should become aroused over this unwarranted waste and demand mining methods and conditions which will conserve the resources of the state.

Mining conditions in this state differ from those found elsewhere, chiefly by virtue of the peculiar character of the roof. This contains a large proportion of limestone, which is easily slacked by the air current and requires great care and an unusual amount of timber to keep it secure. Nearly all the mines of this field are generating large quantities of gas and have to contend with a particularly combustible form of dust, but thanks to competent management and supervision and a strict enforcement of the mining laws, there has been a great decrease in the number of fatal accidents, which is especially gratifying when compared with the number reported in other fields operating under similar conditions.

*Chief mine inspector, State of Oklahoma, McAlester, Okla.

Bituminous Mines, Pennsylvania, 1911

Editorial Correspondence

The operators of the northern part of the bituminous coal field are being driven southward by the rapid depletion of lands in Mercer, Tioga, Elk, Jefferson and Clarion counties, and have invaded Indiana and Armstrong.

Improved extraction methods are not spreading. New mining law subjected to much criticism.

There has not been a large amount of development in the bituminous regions during the past year owing to the small profits in recent mining. The great advances of the past few years have been in the center of the state, where large developments have ben made in Indiana and Armstrong Counties.

The Buffalo, Rochester and Pittsburg Railway has not been slow to realize that the depletion of the resources in Jefferson and Clearfield Counties must be met, and more than met by developments elsewhere, in order to provide traffic for the road on which they are continuing to make large and expensive improvements. These developments, their allied interests have sought to make in Indiana, where the same beds which they have mined in the past, to wit, the Lower and Upper Freeports are situated so far below the water-level, that the area they cover is almost co-terminus with the boundaries of the County. These coals are situated about 75 ft. apart, and are therefore both workable, the extraction of the one not interfering with the later extraction of the other.

This year large developments have been made at the Lucerne plant including the placing of steam turbine generators, and the erection of a large steel tipple, capable of handling several thousand tons a day. The mines are in the Upper Freeport, as are those also at Ernest, but at both mines it is the intention to sink to the lower bed, so that a large tonnage will be available. A branch has been built to Jacksonville, and a big mine is under development at this point.

Armstrong County Development

The receivership of the Buffalo & Susquehanna Coal and Coke Co., has prevented any important developments, and the main interest has been centered around the abandonment of a well-equipped shaft at Onondaga near Big Run. The Allegheny River Mining Co., has profited by the extension of the Pittsburg Shawmut & Northern R.R. from the village of Knoxdale in Jefferson County to the Allegheny River. This extension has a low gradient for a road which crosses several summits and it is well fitted for handling a large tonnage. The Allegheny River Mining Co., an allied corporation, has two mines locally known as Oakland and Tidal Mines. The latter is ready for operation and has been renamed Chickasaw. The Oakland operation will also soon be shipping coal.

The extension of the "Shawmut" line down to Nicholson Run below Kittanning, has been largely graded and can easily be prepared for traffic. Several mines have been opened and much work done on Limestone, Brunner and Nicholson Runs. It is understood that what little work remains to be done to complete the extension to Nicholson Run will be completed, to the end that a large acreage of coal lands lying adjacent to the proposed route, and owned by the Allegheny River Mining Company may be developed. It is proposed to erect a large central power station at Glade Run for the use of these mines. A line of road has been surveyed toward Butler, and if this line is completed a large undeveloped part of Butler County may be open for operation.

Along the Allegheny River

Travellers passing along the Allegheny Valley by the Pennsylvania R.R., formerly the Buffalo & Allegheny Valley Ry., have long wondered that the left bank of the stream was well developed, while the right bank showed few houses and no mines. The work of the "Shawmut" interests give assurance that the right bank will now be well occupied and even more prosperous than the other, because the mines will be in the hands of larger and more adequate financial concerns, having a steady market for their coal.

From Parkers Landing southward, the coal measures are continuous, yet to the point (Kiskiminetas), where the West Penn R.R. crosses the Allegheny River, no shipping mines were formerly to be seen, though just over the ridge near Red Bank an exception might be found in the mines of the Great Lakes Coal Company at Caylor, these mines being tributary to the Allegheny and Western R.R., an extension of the Pittsburg, Bessemer & Lake Erie R.R.

Change of Working Seam

The bituminous area under operation will soon be measurably constricted unless coal is discovered in the Kittanning measures over a large area where it is now believed to be of little value But little coal remains in Elk County. The two principal holders of coal in that county, the Shawmut Mining Company and affiliations, and the Northwestern Mining & Exchange Company, have both made their more recent extensions in other counties, owing to the restrictions in their home county. Clearfield County may hold its own for a while, and perhaps even increase, but this increase will largely come in the lower measures especially in the Lower Kittanning Bed in which—and in a lower seam—nearly all the operators along the Moshannon and its branches are now working.

The Lower Freeport Bed, the stand-by seam of Jefferson County, and an important seam in Elk, Clearfield, Clarion and Armstrong is marked by extensive "wants," sometimes reaching a width of two miles. These wants which are erroneously called faults, and which are the channel beds of streams existent in the carboniferous period, have reduced the available area of Freeport coal considerably. As the beds lie high on the hills, modern erosion has combined with ancient to make the area to be mined limited. In Elk County, no Freeport coal is being mined, and in Clarion County but few mines are working it. In Jefferson County the depletion is very rapid and exhaustion is drawing near. In Armstrong and Butler Counties a large amount still remains.

The ratification of the plan by which the Pennsylvania Coal and Coke company was reorganized promises a new life for that company in Cambria and Clearfield counties. The slack watering of the Allegheny River beyond the mouth of the Mahoning, as recommended by Major H. C. Newcomer, if completed, will enable coal to be loaded in barges and shipped south from many mines, which have so far been tributary entirely to the Buffalo market. This overstocked mart should feel this relief, should the much desired plan ever advance beyond the Newcomer report.

Methods of Coal Extraction

Though as far as the United States is concerned, careful and conservative methods of coal extraction originated in the Connellsville region of Pennsylvania, yet it cannot be said that Pennsylvania is leading other states in this matter. Other sections seem prepared to let Connellsville have proud preeminence, and mining is generally by the primitive advancing room-and-pillar methods providing a great number of short, unreliable lines of roof fracture. There does

not seem any disposition to improve methods except in the leaving of larger pillars and in more speedy pillaring. In the Freeport beds there seems to be no great loss apparent from such primitive methods, because the roof breaks easily and the cover is light. But in the Lower Kittanning mines, the roof is quite strong, and the cover heavier. The coal and development lost in this bed is often large, and in Cambria county an attempt has been made to avoid this by strengthening the weak spots which, unfortunately, may be expected to occur in headings on that side where the rooms are turned off. This is effected by driving rooms with long distances between centers, in fact double the ordinary distance, other rooms being started from the cross cuts out of these first rooms as soon as a sufficient pillar, of about 100 feet, has been left to support the heading. Thus every room approaching the heading serves as the roadway of two other rooms.

First Costs of Complete Plants

Operators have, for many years, been of the opinion that as coal was cheap there was but little economy in saving steam by any of the approved methods recommended where coal costs $5 per ton delivered. Till recently all economies have been directed solely to saving labor by the use of coal-feeding devices at the furnaces with the commend able idea of reducing labor costs and making steam with inferior coal. Some still argue volubly for the belief that coal which is a drug on the market, as is slack most of the year, should not be saved at the expense of any outlay on equipment.

For this cause, uncovered pipe lines, leaky furnaces and bad pipe joints remain unregarded at small plants. Even in larger plants, noncondensing and reciprocating engines still hold their own. But there is gradually working the idea that it is cheaper to conserve fuel not for its own sake, however cheap it may be, but because the conservation saves labor in firing, makes a better plant, and above all one that costs no more. It is an undesirable practice to increase boilers and engines in size and number of units above the call of prudent necessity, when with economy in using steam by means of superheaters, feed water heaters, turbines, condensers, electrical high pressure transmission, and careful upkeep of details the plant could be kept down to normal size. It is being realized that a good plant burns less and poorer fuel, gives a steadier power delivery, saves labor the year around and costs at the first outlay but little if any more because the price of economical devices is offset by the reduction in size and in number of the large units. These factors, whilst they do not make great headway at the older plants are receiving more consideration where new mines are opened. The older mines must eventually be reequipped and it is not infrequent to find the dates of power development marked plainly by the new mechanical designs in the power house.

The New Mine Law

The new Pennsylvania Bituminous Mine Law was approved June 9 of this year. It has occasioned no little unfavorable comment. Before it was finally framed a vigorous protest was made to all the new provisions, but at length the law was enacted and the whole Code fills 136 pages. It is one of the most complete mining codes on record. Its principal fault is its obscurity. There is evidence of the stress of conflict out of which it emerged, but it is probable that the conflict alone is not responsible for its illogical arrangement. Article XI is entirely new. It deals with the installation of electricity in the mines at length, devoting 24 pages to the subject. The uncertainty of the meaning of the law made some operators make the declaration that they would remove their firebosses from the mines. This was perhaps not stated in real earnestness. But the Chief of the Department of Mines wrote a strong letter to them urging the retention of all the firebosses employed. It remains to be seen whether a code specifying exactly what shall be or shall not be done is as good as one leaving larger power of control in the hands of the inspectors.

The Pittsburg District in 1911

By B. E. V. Luty*

The financial results of the year 1911 in the Pittsburg district coal trade were unsatisfactory. Demand was lighter than in the previous year, but with ample car supply and increased capacity the production was only a few per cent. less than in the previous year, with the result that prices suffered throughout the year.

In 1910 the $1.15 price for mine-run was maintained practically throughout the year, but there was an advance to $1.20@1.25 after the wage increase accorded for the biennial period beginning Apr. 1. In 1911, on the other hand, the $1.15 price scarcely prevailed at any time, and was frequently shaded by as much as 10c. per ton on important contracts, while occasionally odd lots forced on the market brought less than a dollar. Large operators were slightly helped in their year's average, however, by the existence of long-term scale contracts, based on the mining rate. These, while on the whole calling for low rates gave a fixed price equal to that of the last nine months of 1910, and above that of the first three months of that year. The average realized price on all the coal mined in the district probably fell between 5c. and 10c. below the average of 1910, which with a slight decrease in the total tonnage made the year an unsatisfactory one.

Definite steps were undertaken in the year to improve the position of the Pittsburg district in the lake coal trade, the case of the 88c. rate from the Pittsburg district to the lakes being brought forcibly to the attention of the Interstate Commerce Commission. The contention was based on a comparison of ton-mile rates with West Virginia and other districts having much longer hauls but only slightly greater total rates to the lakes. A reduction to 50c. was asked, and the Commission is expected to order some redress, though hardly as great as asked.

Early in June the United States Steel Corporation purchased the entire coke operations and coking coal holdings of the Pittsburg Coal Co., involving about 7000 acres and 956 ovens, paying a flat price of $1450 per acre. Making allowance for the value of ovens and other improvements the price was computed at about $1,000 per acre for the coal land alone. At the same time the steel corporation purchased the coking coal of the Monongahela River Consolidated Coal & Coke Co. paying $850 an acre for about 9000 acres of undeveloped land. In each case payment was made by bonds on the properties, guaranteed by the steel corporation. These operations put the Pittsburg Coal Co. in position to retire some of its debt, at the same time undertaking to absorb the outstanding stock of the River Coal Co., in which it had previously owned only a controlling interest. The intention is probably to ultimately absorb the properties and divert much if not all of the output to the rail instead of the river trade.

Production of coke in the Connellsville and lower Connellsville region was about 16,000,000 net tons, a decrease of

*Bessemer Bldg., Pittsburg, Penn.

about 15 per cent. from the preceding year and of 20 per cent. from the record year 1906. This was partly due to decreased consumptive demand, due to lessened output of pig iron, but it was also due in part to development of other fields, and in part by reason of the adoption of byproduct ovens. The Connellsville region shows no indication of ever adopting byproduct practice, though it has rapidly been making improvements in recent years by the adoption of the rectangular push oven, involving a slight decrease in cost of operation.

Coke prices in 1911 were altogether unsatisfactory. The market price for spot furnace coke occasionally ranged above $1.50 at ovens, but as frequently below, and an average of monthly quotations indicates an average for the year of $1.50. Contracts made for the year, chiefly in December, 1910, were mostly at from $1.55 to $1.65, a number of scale contracts (coke to be settled monthly at a stated fraction of the prevailing price of pig iron) being made with minima of about $1.60, the minimum prevailing throughout the year. Contracts for 1910 had been made quite largely during the boom in the closing months of 1909, and showed a much higher average.

The monthly prices for Connellsville coke during the year just closed were as follows:

PRICES OF CONNELLSVILLE COKE.

	Furnace.	Foundry.
January	$2.60	$3.05
February	2.25	2.75
March	2.00	2.60
April	1.80	2.40
May	1.70	2.25
June	1.65	2.20
July	1.65	2.15
August	1.65	2.15
September	1.60	2.15
October	1.55	2.10
November	1.45	2.00
December	1.50	2.00

Coal and Lignite in Texas

By William B. Phillips *

The production of coal in Texas will be about the same as last year and may be taken at a million tons, an equal amount of lignite also being produced.

The coal producing counties are: Erath, Jack, Palo, Pinto, Parker, Wise and Young in the North Central coal field and Maverick and Webb in the Rio Grande coal field. The north central coal field is of the Carboniferous and the Rio Grande coal field of the Upper Cretaceous or Tertiary period.

Most of the coal mined in Texas is for railroad purposes, not much of it being sold for domestic use. The total coal area is probably about 13,000 sq. miles, with an original supply of 8 billion tons. As a rule the seams of coal are comparatively thin, less than 30 in., and the usual ash content is 16 per cent., with sulphur 2 per cent. The heating power of these coals is, on the average, 11,000 B.t.u. and the weight per cu.ft. 87.5 pounds.

Lignite

The production of lignite will be about one million tons, or nearly the same as last year. Workable beds of lignite occur in 43 counties and the total area is about 60,000 sq. miles, or one-half of the total known lignite area in the United States. The deposits run in thickness up to more than 15 ft., and every variety of lignite is represented.

Production of Gas From Lignite

There is now much interest being taken in the production of gas from lignite, especially for power purposes. There are 56 gas producers in Texas and 47 were in active operation during the year. some of them, however, only intermittently. There are 23 establishments making producer gas from lignite and the consumption of lignite for such purposes is about 80,000 tons a year.

In this state 11,490 engine horse power is derived from lignite gas. Most of these installations are of small size, as two establishments alone represent 7,700 horse-power. Producer gas made from lignite is in successful competition with natural gas. No briquets are made in the state and there seems to be but little interest in this matter. Some of the Texas lignites make an excellent briquet without artificial binder.

A Central Power Station

Certain interests have considered the practicability of making producer gas from lignite at some central station, near regular supplies of this fuel, and transforming the power into electric current for distribution to cities and towns. In this direction there might be opportunity for a considerable business, as the price of lignite, at the mines, is about 90c. a ton. From a ton of good lignite there can be produced from 60,000 to 70 000 cu.ft. of producer gas, with a heating power of from 125 to 150 B.t.u., per cubic foot. As byproducts, there would be tar and ammoniacal liquor, the former yielding light oils and paraffin, the latter yielding sulphate of ammonia.

*Director Bureau Economic Geology and Technology, Univ. of Texas.

Utah Statistics for 1911

By J. E. Pettit*

The production of coal for this state for 1911 is 2,501,472 short tons, a decrease of 24,622 tons when compared with production for 1910. The reason for decrease is attributed first to the open winter of last year and the falling off of orders during the first three months of the year. Later during the fall a continual shortage of railroad cars has been experienced.

The production of the hydrocarbon mines is 37,050 tons, an increase of 9501 tons over 1910. The production of coke was 212,368 tons, an increase of 66,304 over 1910, attributed to the fact that the Utah Fuel Co. secured some of their old contracts from the Amalgamated Copper Co. that were rescinded two years ago.

The amount of explosives used was: Black powder, 398,285 lb.; giant powder, 301,792 lb., which includes Monobel, Bental No. 2 and other permissible powders, a total of 700,067 lb., or one pound of powder for every 3.57 tons of coal mined. This shows a decrease in the amount of black powder used during the year, and a corresponding increase in the permissible powders.

Nearly 4000 Men Employed

The total number of men employed inside and outside in both the hydrocarbon and coal mines and coking plants was 3798, an increase of 499 over the preceding year. The average number of days worked at the various mines was 252, and the average amount of coal produced per man was 712 tons.

There were 84 accidents in and around the coal and hydrocarbon mines, of which 16 were fatal, 18 serious and 50 nonserious. There was one fatal accident occurred outside of the mine. Seven wives were left widows and 21 children fatherless. The per cent. of fatal accidents for the year 1911, both inside and outside, was 4.21 per 1000.

The amount of coal mined for each life lost was 156,342. The causes of the fatal accidents were: Falls of rock, 4; falls of coal, 8; runaway cars, 2; boiler explosion, 1; loaded trip of cars, 1.

*State coal mine inspector, 501 Dooly Block, Salt Lake City, Utah.

Virginia Coal Output increasing

Coal mining in Virginia has made important increases within the past generation. Although not a great coal State Virginia produced over six and a half million tons in 1910. The State is one of the earliest producers, the figures of the United States Geological Survey showing a small output as far back as 1822. In 1850 the production was 310,000 tons and at that time only two States stood above Virginia. While other States were forging ahead the increase in Virginia was slow until about 1895, when 1,368,324 tons were produced. In 1900 the production was 2,393,754 tons; in 1905 it was 4,275,271 tons; and in 1910 it was 6,507,997 short tons, the greatest in the history of the State.

Washington State Coal Statistics

The table shown below gives the detailed statistics of the coal industry in Washington for the fiscal year ending June 30, 1911:

Coal in West Virginia

With the close of the present year and the coming of a new one the coal men of West Virginia find conditions greatly improved over those of a year ago. In fact, it was only at the close of the year that conditions changed and brought hope for better things. The spurt in prices, of course, is the real blessing the holiday month brought, and even something a little better is predicted for the months of January and February.

For the calendar year the output has been above that of any previous year, but it is believed that statistics will show that the cost of production will be greater than previous years, while the price received for coal has been exceedingly low. These estimates are based on facts as found by some coal men in their own operations and are believed to hold generally throughout the state. With the increase in the price of smokeless and the expected increase in other coals, the new year presents a cheerful outlook as compared with the beginning of the one now closing.

Imports of Coal in 1911

The total imports of coal for the first ten months of the year just closed amounted to 998,795 tons, as compared with 1,628,111 tons for the same period in 1910. The total estimated imports for the current year will be about 1,198,500 tons as compared with 1,991,943 tons for 1910. By far the largest percentage of this coal comes from Canada, only about one-tenth being imported from other countries, of which Australia and Tasmania are the leaders. The imports are confined almost entirely to bituminous coal, no anthracite being imported in 1910 and only 42 tons during the first ten months of 1911.

Because of labor troubles in the British Columbia field, the figures for 1911 are not representative of the normal condition of this trade. Canada is by far the largest exporter into the United States and the shut-down of the British Columbia mines during two-thirds of the year, has made an appreciable difference in these figures.

COAL STATISTICS FOR THE STATE OF WASHINGTON, FISCAL YEAR ENDING JUNE 30, 1911

Compiled by D. C. Botting, State Inspector of Coal Mines, Seattle, Wash.

NOTE—21,688 tons of coke were produced in Pierce county.

West Virginia during 1911

Special Correspondence

The production of the West Virginia mines for 1911 will probably exceed 60 million short tons, the largest output the state has known. Conditions generally have been satisfactory.

West Virginia has at least made progress in three directions during the past calendar year—in production, in price of coal and in the methods of mining with a view to the greater safety of men and property and a reduction of costs. In other words, the practical side of mining has been sought and practiced, where for years the mining department of the state has struggled in vain to change policies.

Production and New Developments

The new development during the year was, briefly, the establishment of 18 new coal plants, the construction of 55 new power plants, the erection of 25 mine fans, 15 tipples and about 25 additional openings to old mines. This, however, does not mean that the above number of mines have been added to the number that existed on Jan. 1, 1911. On the other hand, a number of mine openings have been closed. In fact, a much greater number were closed than were opened, so that the number of mines, or openings, is much less at the end of the calendar year of 1911 than at the beginning.

The official statistics in the office of the Department of Mines show the total net ton output for the calendar year of 1910 was 60,099,239. While it is not possible, at this time, to get the exact tonnage for the calendar year 1911, the department of mines has sufficient information to form the belief that it will be at least 60,500,000 net tons, or an increase over 1910 of something like a half million tons. The fiscal year in the mine department in this state ends on June 30, and therefore to secure the calendar-year statistics it is necessary to go into the statistics of two years, and to the fact that the mine year does not end with the calendar year is doubtless due the many conflicting statements relative to the statistics in this state.

Early Statistics

The first statistics on mining in West Virginia began with the year 1863, when the output was 444,648 net tons. Since that time there has been an increase in output every year, with the exception of the years 1876, 1881, 1895, while the output in two years is given as the same—it not being possible to secure the exact tonnage. The biggest advance, however, came in 1910, when the output increased from something below 50 million to a little over 60 million net tons.

The output for the first six months in 1911 was not encouraging, when compared with the last six months in 1910, as a decrease of a little over three million tons was found to exist, but the output the last six months has been so great that the decrease was wiped out and an increase shown.

Price Improvement

One of the greatest improvements in conditions is the increase in price. Although small, and most of it due to the increase during the last month or two, it indicates a better outlook for 1912. The authority for this statement is the present head of the mining department, John Laing. Speaking about output and price, he said:

I think the output for 1911 will reach 54 million gross tons, provided the Christmas holidays do not make a greater deduction than usual. The price of coal, f.o.b. cars at the mines, from such information as we are able to gather will be 96c. a short ton, on the mine-run basis, which is about one cent better than for 1910.

While the production of coal in this state is rapidly increasing the prices at the mine stand about the same, which shows conclusively that the quality of West Virginia coal is superior to that of our competing states which are more favored in the question of freight rates. The difference in freight rates for West Virginia coal, you might say, is added to the cost of coal to the consumer, or, in other words, our competing states receive practically the same price that West Virginia receives. I believe the price of coal to West Virginia operators has gone as low as it will ever go and I can see no reason why it should not gradually increase until it reaches what we might call a fair return for our product. The operators of West Virginia are not receiving the same interest on their investment as the operators of other industries on theirs and at the same time the coal business is responsible for other industries in West Virginia.

The production of coke has decreased about 50 per cent. during 1911, and will not greatly exceed two million tons. The operators find it almost impossible to manufacture coke at the present market price, especially while the price of West Virginia coal is near normal. The ovens are gradually being closed all over the state. The price of coke this year has been about $1.80, net, at the mines, against $1.83 in 1910. It is the belief of Mr. Laing that if all the ovens in the state were closed, the production of coal would not show any considerable falling off.

The state has been free of labor troubles during the past year. Several of the mines had trouble with their men, but the difficulties lasted but a few days. In fact, these occurred at only four or five mines. The statistics show that about 72,000 men were employed in and around the mines, exclusive of superintendents, mine foremen, managers, store and office forces.

Accidents

Unless there should be additions for the closing days of December, of which the mine department has received no information, the total fatal accidents for the year will be 325—a slight decrease over 1910. The nonfatal accidents totalled 770—also a slight decrease over 1910. The state had two explosions during the year. At the Ott mine, of the Davis Coal & Coke Co., at Thomas, 20 lives were lost, due to a gas and dust explosion. At the Bottom Coal & Coke Co.'s mine, at Vivian, 18 lives were lost, caused by men entering an abandoned section with open lights. In 1910 there was but one, causing the death of three men. Speaking of the accidents in mines, Chief Inspector Laing said:

I regret that reports received by this department show that 80 per cent. of the fatal accidents were caused by carelessness on the part of workmen themselves by going in dangerous places after being warned not to do so.

One thing that entered into, and probably made possible the increase in output in 1911, was the supply of cars. There was, in fact, no serious shortage of cars at any time during the year—a condition that has never before prevailed in West Virginia, in the opinion of some of the oldest miners. The railroads have made great improvements in equipment and facilities for handling coal, and their interest in trying to handle the output has received coöperation from the operators, and instead of being at "outs," the operators and railroads have been working in harmony and friction was little known.

One of the greatest changes in the industry has been in requiring every mine foreman and fireboss to hold a certificate obtained at an examination held under the supervision of the chief of the Department of Mines. These examinations have been held during the year, and beginning with Jan. 1 no mine was permitted to be operated that did not employ a mine foreman and fireboss (if one was necessary) that did not hold a certificate. The department has also laid down other important rules in mining, all leading to the one thing—efficiency of the persons holding responsible positions—and the operators have agreed to coöperate with the department in carrying out the instructions.

Coal and Coke Exports in 1911

Editorial Correspondence

The export tonnage of the United States is increasing rapidly as compared with that of other countries. During the past 12 years this trade has trebled in value and for 1911 will amount to more than 80 million dollars. Exports are largely to Canada. Alaska is buying more coal each year.

According to the Bureau of Statistics of the Department of Commerce and Labor, the coal exports from the United States have trebled in value in the last dozen years. The total value of the coal exported in the year of 1911 is in round numbers, 80 million dollars, as compared with 65 million for 1910.

The United States now ranks third among the coal exporting countries of the world, being exceeded by the United Kingdom and Germany, who exported in 1910, 179 million and 104 million dollars worth of coal respectively, while the United States exported only 45 million, exclusive of bunker coal. However, the growth of the United States export trade is increasing much more rapidly than that of any other country, as may be shown by comparing the export figures of 1900 and 1910. During this period the export coal trade of the United States has increased practically 100 per cent., Germany 60 per cent., while that of the United Kingdom has suffered a slight decrease.

The principal destination of our export coal is to Canada, as shown by the figures for the first ten months of 1911, during which period our total exports of bituminous were valued at $28,732,888, of which $21,510,604 was shipped to Canada. Because of the strike of about eight months duration in the British Columbia fields our exports to this trade have been abnormal during this period. The next four important export markets are Cuba, Mexico and Panama, each taking between one and two million dollars worth annually.

As compared with our other exports, coal now ranks seventh in importance, being exceeded by cotton, iron and steel, meat and dairy products, copper, wood manufactures, wheat and flour.

Quantities of Exports

The total exports of anthracite for the first ten months of 1911 were 3,016,127 tons, as compared with 2,483,413 tons for the same period last year, showing an increase of approximately one-fifth. This trade is almost entirely with Canada, only a very small portion going to other countries. An approximate estimate of the total anthracite exports for the year of 1911 places this tonnage at about 3,620,000 long tons, as compared with 3,021,627 tons for the year of 1910, showing an increase of nearly one-third in the export anthracite trade.

The total exports of bituminous coal for the first ten months of the year just closed were 11,643,931 tons, as compared with 9,105,787 tons for the same period in 1910. These figures do not include bunker or fuel coal laden on vessels in the foreign trade which aggregate 5,578,497 long tons for this period in 1911.

Of the total bituminous exports, 8,933,044 tons were shipped to Canada, and, for the same period last year, this amounted to 6,432,632 tons, showing an increase of approximately one-third in this trade alone.

The total export bituminous trade for the year of 1911 is estimated at about 14 million long tons, as compared with 10,784,239 long tons for 1910. The total bunker or fuel coal laden on vessels in the foreign trade will be approximately, 6,700,000 long tons, as compared with 6,445,593 long tons in 1910.

Gross Estimates for 1911

The total shipments of both bituminous and anthracite coal, including that laden on vessels in the foreign trade will, for the year 1911, be approximately, 24,320,000 long tons, as compared with 20,251,459 tons for 1910.

The total exports of coke for the first ten months of 1911 were 777,861 tons, as compared with 715,196 tons for the same period in 1910, showing a material increase in this department. The total exports of coke for the entire year are estimated at 933,400 tons, as compared with 879,073 tons for the year of 1910, showing a material increase in the coke trade for the year just closed.

While the figures in our export trade for the year now closed show heavy increases all along the line it should be remembered that conditions have not been normal during this period. The British Columbia mines during about two-thirds of 1911 were practically closed down and since Canada is the destination of fully three-fourths of our export coal this has necessarily caused a heavy increase in shipments to that market.

Exports to Panama

As a natural result of the activity at the Panama Canal, exports of fuel to that trade has shown a steady and heavy increase during the last few years.

In 1908 the total exports to Panama amounted to 345,464 tons valued at $909,512. In 1909 this trade increased materially, the total tonnage for that year being 427,462 tons valued at $1,168,774. An increase was still evident in 1910, but not of such proportions as that for 1909. The total tonnage for 1910 was 497,316 tons, valued at $1,321,378. The total tonnage shipped to this trade for the first ten months of 1911 was 417,476 tons, valued at $1,071,494 and it is estimated that for the year of 1911 these exports will amount to slightly over a half a million tons.

Philippine Islands

For the first time in a number of years no coal has been exported to the Philippine Islands. In 1909 there were exported to this point, 155,655 long tons and in 1910 the exports amounted to 118,389 tons, while for the present year the Islands are apparently drawing on their own supply.

Exports to Porto Rico

Our Porto Ricoan export trade is not well established yet and a review of this market over the past three years shows considerable fluctuation in tonnages. In the main, however, this trade appears to be on the increase. In 1908, the total shipments of both bituminous and anthracite to Porto Rico amounted to 88,624 tons. In 1909 this trade fell off to 75,927 tons, valued at $232,679. In 1910 another heavy increase was experienced, the total exports for that year being 108,105 tons, valued at $333,547. The total exports for the first ten months of 1911 were 86,745 tons, and the total tonnage for the year is estimated at 104,000 tons, or about 4000 tons less than for 1910.

Alaska

Exports to Alaska, while comparatively light, continue to show an almost uninterrupted increase.

For 1908 the total of both coal and coke amounted to 21,509 tons valued at $137,567 and for the year following the tonnage was 29,684 tons valued at $191,420. During 1910 the tonnage fell off slightly amounting to only 28,833 tons valued at $177,127.

The total shipments for the first ten months of 1911 were 28,277 tons valued at $158,224. For the entire year it is estimated the shipments will total more than 30,000 tons the largest tonnage yet recorded.

Coastwise Trade Conditions in 1911

By J. J. Wolkins*

Coastwise tonnages for the year have been unusually heavy, particularly in anthracite. Some new high rates on water freights were recorded.

*50 Congress St., Boston, Mass.

In New England, 1911 was a year of large tonnages. Receipts at the port of Boston were well in excess of 1910, both in anthracite and bituminous, and had soft coal yielded better prices, the dealers generally would have called it a fairly good year. The early months were favorable to coal consumption, and were followed by a prolonged dry season cutting down the supply of water power for the mills. Then in August began the most unusual succession of fogs and gales that prevailed through the fall months and sent freights up to more than double the summer figures.

The Bituminous Trade

The bituminous trade has been the despair of the larger agencies. A weak situation early in the year gave little hope for fair prices, but for a time it seemed the West Virginia operators might settle their differences. All efforts, however, proved futile, for no sooner had the season opened strong with a contract price of $2.70 f.o.b. Hampton Roads, Va., or $3.63 gross tons weighed on cars at Boston for inland delivery, than an open cut was made March 31, to $3.30 on cars for the year, a price based on the water freights then current and netting less than $1 at the mines for the best brands of Pocahontas and New River.

Market Settled Into Dullness

For awhile the low values of 1909 looked certain to be duplicated, but at length, after all sorts of efforts to save the season, the market settled into a summer dullness at a range of $2.40 to $2.50 f.o.b., less selling commission, and $3.10 to $3.20 on cars at Mystic Wharf. Buyers were encouraged to hold off until minimum prices were to be had, and all the shippers were not only long on coal, but most of them were forcing supplies on the market rather faster than they could be absorbed. This condition held until late in August or September when large consumers began to worry over the slow movement of water transportation and pressed for deliveries on their low-priced contracts.

Bottoms were making but three trips when normally they would have made five and six, and with several heavy losses besides, by wreck and partial damage, a serious shortage became apparent late in September. Water freights advanced on big vessels, Virginia ports to Boston, from 60c. to $1.25 within a few weeks, and at the end of the year there was only a slight recession to $1.10 and $1.15. Coal at the loading ports is now reported to be in short supply, and for spot shipment would command a higher price than was secured on any contract business the year through. Current prices on cars Boston are around $4.00, and most of the shippers have been obliged to buy outside at present prices in order to tide over customers until they could make deliveries of their own.

A Lesson to West Virginia Operators

The year's experience should be valuable to the West Virginia operators for it must have shown how easily a big tonnage can be thrown away, with no adequate return. In a word, the trouble has been an over anxiety on the part of too many sales agencies to place tonnages in this market, without apparent regard to the returns that would have to be made later. If there was one feature worse than another, from April to July, it was the practice of sending cargoes here unsold, and them hammering prices to attract small buyers. So long as "protection" is guaranteed the buyer, the slow season can never be improved until the "auction hazard" is eliminated.

The principal Georges Creek shippers have apparently enjoyed a satisfactory year. They have an advantage of 15c. in rate to tide over West Virginia mines, and with an ample fleet of steamers, tugs, and barges have been able to live up to contract obligations and have coal for sale besides at lucrative figures.

Bituminous all-rail has been heavy all the year. The low prices at tide diverted a large tonnage that would ordinarily be railed from the Pennsylvania districts, and it was to be expected that the mines with less well established selling connections would suffer most. The better known shippers have had to make low prices to keep up anything like a normal output, and prices have ranged down to 85c. on coals higher in ash and volatile. The better grades from Somerset and Cambria counties have lately advanced from $1.20 to $1.35, in response to a slightly better demand.

At tide-water most of the Pennsylvania shippers have been in straits all the season. When Southern prices moved up in October there seemed an opening for a large tonnage from Philadelphia, but rates were soon advanced for shipment in anthracite transportation in sympathy with those from Hampton Roads, and a promising outlook faded away. The retail price of bituminous in Boston was advanced from $4.25 to $4.50, net tons, Dec. 1.

Generally, the 1912 prospect is good for bituminous. The mills and corporations all over New England are enjoying fair business, and each year seems to mark requirements up to a new high figure.

Anthracite

The year of 1911 was a record one for anthracite. The cold easterly weather from January on made stocks unusually light when the shipping season started and the months from March to June a very heavy tonnage was taken on. The usual April demand, both at tide and all-rail, lasted well into the summer, and there was a notable shortage of free stove and hard egg. Indeed the companies are still behind on orders for stove, and there was no apparent slackening in the demand at the end of the year. Early in September a cool wave brought in an extra business and it was not long before the anthracite companies had requests for prompt shipments on all sizes. The slow movement of barges had the effect of shortening up supplies and during October, November, and December the shippers were swamped with orders and there has been anywhere from three to six weeks' delay.

The Situation Grew Acute

In December the situation grew really acute; for the first time in years certain of the producing companies allowed their Eastern storage depots to go practically bare of stock, and with no early replenishing in sight. Warm weather before Christmas relieved the situation somewhat but the last days of 1911 saw the big cities in the market again and eastern shipments as slow as before. Chestnut size has continued in strong demand all the year, and the 25c. advance over the usual circular Apr. 1, has been easily maintained.

The end of 1911 saw another announcement, this time a similar advance in the contract price of broken coal, to $5.00 alongside. These advances, together with those in pea and the steam sizes within a year or two leave stove and egg the only sizes that have not been advanced since 1903. The anxiety over strike possibilities in the spring no doubt accounts in part for the increased ton-

nage in this section, but that does not deprive 1911 of its position at the top of recent years in anthracite.

A Large Contract

The latest "big news" in 1911 was the purchase by the New York, New Haven & Hartford R.R., through its Boston offices, of about 3,400,000 tons of steam coal for delivery during five years for the New England lines of the so-called "Mellen System," including the New Haven Road proper and subsidiary companies like the Boston & Maine and the Maine Central. The contract was made with the Virginia Iron, Coal & Coke Co. of Bristol, Va.-Tenn., operating mines on the Clinch Valley Division of the Norfolk & Western Ry., as producer, and the Coastwise Transportation Co. as carrier.

The biggest steam collier in the trade, the "Suffolk," has been chartered to bring part of this coal to Boston and to Portland, and it is understood that the Coastwise Transportation Co. will at once build a sister ship to the "Suffolk" to assist in carrying the coal. It is believed that the construction of such ships as the "Suffolk" and the "Newton," launched in September, carrying upwards of 7200 tons, and making quick and regular trips, means the passing eventually of the large sailing vessels that have hitherto had most of the coastwise carrying trade. There are now seven of this largest type of steam collier, and some of them have made four round trips from Hampton Roads to Boston within a calendar month.

Review of Year's Coal Trade

By John H. Jones*

Coal production in 1911 while reduced by industrial depression is upheld by increasing domestic uses. Advanced legislation is favored in order to clean the slate and give capital, assurance of stable conditions. Present liability law in case of a severe explosion with proved liability, would fail because of bankruptcy of the corporation involved.

The coal tonnage in the United States for 1911 will nearly equal that of 1910, which was slightly more than 500,000,000 tons, or about 10,000,000 tons in excess of the entire production in this country from the time the first ton of coal was taken from the earth up to and including the year 1871. Not more than 60 years ago, the yearly production of the country did not exceed 7,000,000 tons; comparing this with the more than 500,000,000 tons of 1911, will give some idea of the wonderful strides which the coal industry has made and is making. That the production in 1911 has not shown a decrease over 1910 is accounted for mainly by the fact that while many of our largest manufacturing plants have not operated as fully as in years past, there is a steady increase in the use of coal for gas making, the production of electricity, railroad fuel and domestic consumption.

Production of Coming Year to Be Large

While the production in 1911 has been rather unsatisfactory, 1912 will show (from present indications) the largest production in the history of the coal business, with an increase of from 10 to 20 per cent., or a total of from 550,000,000 to 600,000,000 tons. This, of course, will come from a simultaneous increase in other lines of industry. That increase will be brought about by the willingness of the largest corporations to comply with the law, and their desire to coöperate with the government to bring about better business conditions by legislation which will eliminate as far as possible the discontent on the part of capital caused by the attacks which have been made from time to time.

I think we should urge upon the government the appointment of commissions to settle such questions as monetary and tariff conditions, and, moreover, urge the establishment of a federal corporation law, which would be regulated in such a manner that capital would have a fair return upon its investments and at the same time the consumer be assured of the lowest possible prices for his purchases.

*President, Pittsburg - Buffalo Co., Pittsburg, Penn.

The lake tonnage from all districts, for the 10 years ending 1911, is as in the following table:

LAKE TONNAGE FROM ALL DISTRICTS

	Pittsburg District	Ohio District	W. Va. District	Total
1902	4,704,093	2,689,974	965,769	8,359,036
1903	6,092,047	2,458,265	1,539,435	10,089,747
1904	6,058,383	2,138,247	1,279,876	9,476,506
1905	7,443,883	2,062,692	2,109,262	11,615,637
1906	9,287,272	2,560,906	2,743,732	14,591,910
1907	10,549,993	4,074,296	3,420,941	18,037,232
1908	8,700,000	3,600,000	3,450,000	15,750,000
1909	8,687,305	3,002,815	3,874,570	15,364,690
1910	11,911,900	4,297,300	6,629,500	22,838,700
1911	10,611,941	4,019,544	7,151,200	21,782,685

Employers of labor and their employees should endeavor to get closer together. Union labor should not be criticized for the acts of certain of its officials. The labor unions should discourage, collectively and individually, violence by their members. They should select from their ranks the most conservative and efficient leaders. Capital and labor must recognize that their interests are mutual. Where treating with union labor, capital should insist that the union officials be honorable and intelligent men, in order to deal honorably and intelligently with them. Where labor is not organized, capital should get closer to the men and treat them, as is already done by a large number of companies, in the way it would like to be treated. Capital should do everything possible to disarm labor, whether union or nonunion, of the belief that it is its desire to make every dollar possible from its toil, regardless of its welfare. This is certainly not true of capital in most cases.

The Equity of a Compensation Law

A compensation law, which will provide for a man and educate his family in case of accident or death, will be a step in the right direction. Let us hope that Congress will recommend to the several states that such a law be passed. Let us also hope that no state will hesitate to pass a law which will bring about conditions which mean so much to the workingman and his family. A compensation law which means individual liability for the different companies, to be recovered through the courts of our country, is simply an encouragement to "ambulance chasers," and only pays compensation to the workingman where it can be proved beyond doubt that it was not through his own negligence that the accident happened. Why not pass a law which will pay a fixed amount to those families as long as they are dependent upon the income of the injured or deceased employee? For instance, in coal mining there are not 20 per cent. of the companies engaged in business today who would be able to pay the required indemnity under the liability law in case of a serious accident, requiring them to pay from $100,000 to $1,000,000. In connection with this liability law, the strictest kind of laws should be passed by the states to minimize the number of industrial accidents as much as possible and protect the lives of the workers.

More tonnage will be moved in the early part of 1912 than has ever before been moved in the history of the country. Consumers have been postponing the buying of necessities as long as possible, and supply houses have been postponing the stocking of their warehouses. They are now ordering ahead, and the mills and manufactories have orders to keep them going for the first six months of the year. The possibilities of the last six months will depend to a large extent upon the political situation.

Baltimore and Vicinity in 1911

By Leslie Rawles*

The year 1911 has been one of reduced sales and small profits for Baltimore operators. Yet when an impartial view is taken of conditions as a whole, and the depression which has existed in so many industrial lines throughout the entire twelve months is considered, the Baltimore dealers feel they have no cause for complaint.

Market Conditions

It is true that when the present year made its advent, the hopes of the coal trade in Baltimore ran high. There was every evidence that there would be a general revival of business the country over. Operators had visions of prolonged activity in the steel industry, which would necessarily bring about a constantly increasing demand for their product; they saw an unprecedented traffic for the railroads, and these same railroads purchasing freely, thus stimulating the trade of the car manufacturing and supply companies, and adding zest to the coal market.

These hopes have not been realized to the extent that Baltimore operators had expected. Among the overly enthusiastic ones, the disappointment over the failure of the coal market to exhibit the life that was expected of it, is keen. But the conservative view taken by the trade here as a whole is that the year has been as good as one could expect in the face of the adverse business conditions which prevailed.

The steel industry did not have the boom expected and as these industries are looked upon as large consumers, the coal trade has felt keenly, the lack of orders which usually come from this source. The railroads in the East, and especially those which are closely associated with the business at this port, have had a fairly good year, but their policy of purchasing equipment and steel rails has been what might be termed a hand-to-mouth one and consequently the equipment and car specialty manufacturing concerns have been idle a greater portion of the time.

As a result of such conditions in the business world, the coal trade has been depressed. It is true that during some of the months of the year, coal has moved freely, representing shipments made under contract by Baltimore operators. And it might be said that nearly all the coal shipped in the past few months was called for under contract, but under slightly reduced prices when compared with last year. In this section, renewals of contracts take place around Apr. 1. When this time arrived, some of the consumers came in under prices quoted by operators. Others did not, preferring to hold out and take their chances of getting the product cheaper by spot purchases. Later they did agree to take coal under contract, but, according to authentic reports succeeded in getting a slightly lower price quoted.

The Spot Market

The spot business, which plays so prominent a part in the Baltimore market, has been extremely disappointing. In January this was somewhat brisk, and again in February, operators reaped satisfactory profits from this business. There was an easing off in the demand for coal in March, and during the complete slump which followed, the spot business disappeared. Contract shipments also eased up.

The early spring and summer months brought no improvement in the demand for coal. Inquiry at many of the offices elicited the information that consumers were entirely out of the market, and in many instances, operators disposed of coal at a price below the cost of mining it. Such stagnant conditions prevailed until the advent of October, when there was a slight improvement, as evidenced by the freer movement on the railroads over which Baltimore operators ship their product. The latter part of October found the demand not quite so brisk, and, while considerable coal moved in November, it was mostly under contract. The spot business was lacking, and the market bordering on stagnation.

Operators predict that the tonnage from Maryland and West Virginia mines operated by local companies will probably reach 19 or 20 million tons for next year, providing trade conditions get no worse. The opinion is that business is going to be better, and that the coal trade will share in the general improvement.

New Developments

The improvements which are to make possible this increased output of coal, were, for the most part, started during 1911. Probably the biggest development inaugurated by any company throughout the United States, was that of the Consolidation Coal Co. in the Elkhorn Valley of Kentucky. This company owns a tract of 100,000 acres of high-grade coal, and is spending millions of dollars in developing their property. It began the opening up of between sixteen and twenty mines at various locations on the tract, and expects to begin mining coal within the next two or three months. In addition, the Consolidation has practically completed the construction of the Sandy Valley & Elkhorn Ry., from the Chesapeake & Ohio Ry. at the mouth of Shelby Creek to Jenkins, Ky., the new town built by the company. It is expected that the Consolidation will be shipping 1500 tons of coal daily from this property by April first.

The Consolidation also started construction work on its big electric power station at Hutchinson, W. Va., which is to supply electric power to all the company's mines in West Virginia. It is to be one of the most modern plants in the world, and will have three, 1500 h.p. engines driving three 1000 kw. generators. It will be constructed so an addition equal to one-third of the original plant may be added.

The Davis Coal & Coke Co. did considerable work in the way of opening up additional mines in the Davis vein territory at Thomas, W. Va., four in all being opened. These new mines will be operated under the contract which the company has with the Bethlehem Steel Co., and which runs for 20 years. Delivery of coal under this contract will begin May 1, 1912. An additional mine was also opened up by this company at Dartmoor, W. Va., in the Beaver Creek district.

Three mines were opened up by the Georges Creek Coal Co., Inc., in the Tyson vein in Allegheny County, Md. This company was formerly controlled by the Georges Creek Coal & Iron Co., of Baltimore. The headquarters of the concern are now at Lonaconing, Md.

Of particular interest to Baltimore is the construction of the Buckhannon & Northern R.R., which was begun this year, from Rivesville, W. Va., to the Pennsylvania state line. This road is owned by the Baltimore & Ohio, the Pennsylvania and the Pittsburg & Lake Erie R.R., a subsidiary of the New York Central system. When completed, the new line will tap about 60,000 acres of coal land which heretofore had no railroad facilities. The Little Kanawha Syndicate, which is controlled by these three roads, owns 60,000 acres of coal land to be traversed by the new line, and will open it up for development. It is expected that a large portion of the coal mined on this property will be exported through Baltimore.

*Baltimore, Md.

River Shipments at Pittsburg

Special Correspondence

Figures compiled by the United States Engineers for the first 11 months of 1911 of the amount of coal arriving in the Pittsburg harbor and also that shipped to down-river points, indicate a banner year in the river-coal business of the Pittsburg district. The estimate for December has not yet been completed but already a record breaking shipment has been sent on its way to Southern ports.

Were it not for the fact that during the summer the down-river boats were forced to tie up on account of low water, the coal shipments through Davis Island Dam this year would have greatly exceeded those actually made. During the summer of 1910 good stages of barge water prevailed at frequent intervals and the effect of this on the river shipments can be seen by glancing at the tables given below. But in spite of all this, taking the shipments for the first 11 months of 1910 and comparing them with the same period for 1911, it is found the shipments for 1911 are greater by 485,638 tons. When the December shipments have been tabulated this figure will be yet larger.

The table in next column shows shipments for the first 11 months of 1910 and 1911 in short tons. This table indicates a total tonnage of coal handled through the Pittsburg Harbor for the first 11 months of 1910 of 10,374,055, and for the same period of 1911 of 10,859,693.

The aggregate of the coal tonnage on the Monongahela River is arrived at by taking the coal shipped up through Lock No. 1, plus the amount shipped down through Lock No. 3 and to this sum is added the amount mined and shipped in Pools 1 and 2 on the Monongahela River. The river tonnage on the Ohio River is obtained by adding the amounts shipped, both up and down that river, passing through Davis Island Dam.

OHIO RIVER SHIPMENTS, 1910–1911

	1910		1911	
	Monongahela	Ohio	Monongahela	Ohio
January	796,046	451,350	973,861	574,170
February	902,832	138,680	1,005,741	448,160
March	1,083,251	245,150	1,010,871	271,210
April	234,884	61,950	814,724	430,090
May	936,308	102,275	826,093	102,320
June	989,343	378,280	481,412	55,040
July	867,504	80,520	486,752	27,865
August	763,262	47,940	556,413	160,930
September	754,130	36,770	610,985	157,955
October	701,713	37,380	727,113	159,530
November	684,287	80,200	811,588	166,870
December	759,275	114,265	....	....
	9,472,835	1,774,760	8,305,553	2,554,140
December	759,275	114,265	....	....
11 months	8,713,560	1,660,495	8,305,553	2,554,140

to local points. An example of such a company is the Jones & Laughlin Steel Co., operating mines near California, Penn., in the Fourth Pool of the Monongahela River. Most of the coal mined and shipped by this concern is used at its mills in the Pittsburg Harbor, although of recent years much has been sent through Davis Island Dam to its new plant at Aliquippa, Penn., on the Ohio River.

Less than 10 per cent. of the coal shipped and mined on the Monongahela River is sent South, the larger portion of it being used in the local steel and other mills. According to the Monongahela River Consolidated Coal & Coke Co., one-third of all the coal they mine is shipped to the Southern trade, one-third to the Pittsburg Harbor for local consumption and one-third by rail to the Lakes and the Northwest. However, this company is the largest coal shipper to the South, most of the others confining their trade

Despite the fact that the Monongahela River is slack-watered almost to its headwaters, the frequent stages of low water on the Ohio River, preventing continuous navigation, reacts on the former stream. This is caused by the inability of the operators to bring back the empty barges and coal boats to the local harbor, eventually resulting in a shut down at the mines.

The Mississippi Valley in 1911

By E. J. Wallace*

With the close of 1911 the operators of Illinois have put the year down as one of the most unsuccessful in their history. At no time during the past year has the price of Illinois coal gone beyond normal, and for the greater portion of the year the actual selling price of coal was around and below the cost of production.

The principal reason for this is the fact that the strike of 1910 caused much business that heretofore came to the Illinois field to be diverted to other fields, principally Indiana and West Virginia, and the Illinois operators have been unable to recover this lost ground. Again, the production of Illinois coal is growing twice as fast as a logical market for it is being developed, and the result is that today Illinois can produce twice as much coal as there is any natural demand for in its territory. The development of new mines has not been as extensive in the northern field as it has in the southern, where several new mines have been started or completed in the counties of Williamson and Franklin, and also in that great coal field adjacent to East St. Louis, including the counties of Madison, Macoupin, Montgomery, Bond and St. Clair.

In contrast to this a few mines have been abandoned, but they were of small tonnage, and the closing up of these did not affect the market in the least. The operators in the Illinois field have been hampered considerably by the taking up in a serious way by the miners of petty grievances, and perhaps one important change that would help better conditions was the effort made to use a new explosive in the mines of Franklin County in place of the ordinary black powder. In some mines the operators were successful, and in other instances strikes were local and long.

Costs and Production in Illinois

The cost of coal in the Franklin County field has been increased considerably on account of the operators taking the precaution to guard against coal dust explosions by installing sprinkler systems, and by putting on additional fire runners to guard against fires after the shot firers are through. The "wild-cat" sinking of

*The Dealers' Fuel Co., St. Louis, Mo.

mines has been put a stop to by the law that went into effect over a year ago, which requires all shafts and air shafts to be constructed of concrete, and this has had a tendency to stop almost entirely the promotion of speculative mines. In the coal field adjacent to St. Louis there has been no change of note during the past year, unless it be that the operators are poorer as a result of trying to do business in a shrinking market.

In the central- and northern-Illinois districts there has been no great development to any extent, and the tonnage here as in the southern field has always exceeded the demand. The low coal in this section offers many serious problems that are usually met with locally.

The production of Illinois coal for 1911 will not exceed, it is believed, the production of other years, under normal conditions. It is true that at the present time the state of Illinois, without opening another mine, can produce fully 100 million tons, while the market for Illinois coal cannot absorb more than 50 million tons. It is figured that Illinois coal, during the year 1911, brought between 3 and 5c. per ton less than in the previous year. There are no complete figures at this time to show what the tonnage for the year 1911 has been, but it is estimated at between 50 and 65 million tons. There is practically no coke produced in the state of Illinois, excepting at two or three points, and this production is insignificant when compared to the productions of other states.

Missouri

The year 1911 marked the beginning of the downward trend of coal operations in Missouri. There have been practically no new mines sunk in the state and several of the small older mines have been abandoned. As a whole, there were few mines in the state that made expenses, as the demand for Missouri coal is limited, as well as its market. This, chiefly on account of the higher grade coals produced in the other states surrounding. The Missouri coal market has been lost chiefly to coal from the Carterville and Springfield districts in Illinois, and there seems to be no hope of recovering this lost ground.

There is a feeling against the development of any more coal lands in Missouri on account of the low vein, and the high mining scale, and it is expected that from now on every year will show a lower figure in the coal production for this state. No coal produced in the state of Missouri reaches the St. Louis market, although a fair tonnage from the central western portion gets in to Kansas City and St. Joseph, and the market in the former city is limited on account of the use of natural gas.

Arkansas

The situation in Arkansas is a peculiar one, and it has developed so during 1911. In the semi-anthracite field of Arkansas there has been a good demand for the coal, and the market has been widening to some extent. This coal is gradually growing in favor on account of its superior quality, although it is produced under difficulties that are experienced in but few other mining sections. However, the cost of production is so great that only by the aid of favorable railroad rates can this coal compete with the higher-grade coals of other fields, but where these rates are practically the same, Arkansas coal is almost eliminated.

In the bituminous mines there has been no notable increase in the production as this coal is not of that superior quality where it can win its way into foreign markets. However, as the state of Arkansas is developing fast it will continue to create a growing market, which will no doubt take care of the present tonnage for the next few years, but if further development of the coal is contemplated, the condition in Arkansas will be much the same as it is in Illinois. During the past year three of the largest cities in the state have practically abandoned the use of coal, for natural gas and oil. Every city and town on the main line between Little Rock and Texarkana are now using natural gas from the Louisiana fields, and the same condition exists at Pine Bluff. In sections isolated from the gas mains the steam plants are looking with favor upon fuel oil, and there is nothing promising for future steam-coal production in this state. The encroachment of oil and gas, while affecting Arkansas production, is also hurting the operators of Illinois and to a greater extent in the southeastern portion of Missouri, and northern Louisiana.

Great Britain's Coal Industry, 1911

Special Correspondence

The British coal industry was considerably affected during the past year by labor troubles, especially in South Wales, and by the recent railway strike. Yet in spite of these difficulties, the pessimistic utterances of the president of the British Association, and the lamentations of the statisticians, to the effect that coal mining is not profitable below a certain depth, the industry, as a whole, is cheerful at the beginning of the year 1912.

Yorkshire

The various coal fields are producing up to their maximum output except in Yorkshire, Nottingham, and a mine or two in South Wales. It has been reported during the year that Yorkshire is underlaid by a vast coal field which was previously unknown and that in the course of several years 40,000 miners would be given employment in this region. But such is not the case. On the contrary, signs are not lacking to indicate that the remarkable development begun in South Yorkshire in 1900 has already reached its climax. This fact is due to the geological conditions that make shaft-sinking extremely expensive; the coal measures being overlaid by Permian and Triasic formations which contain quicksands and large volumes of water.

At Thome colliery as much as $1,250,000 has been spent the past year in sinking two shafts to a depth of 600 ft. each, owing to the fact that it was necessary to pump out 9000 gal. of water per min. The ultimate depth of these shafts is to be 2760 ft. At the Halfield main colliery, near Doncaster, the "Francois" system of injecting cement into the strata as a preliminary to shaft-sinking was tried for the first time in Great Britain.

The Midlands

During 1911, six new colliery companies started shaft-sinking in the Midland coal field, each mine being designed for an output of at least 1,000,000 tons per year, and altogether there are now 12 shafts being sunk in this locality. The increase of production in the Midlands has overtaken and exceeded the export trade with the result that a number of the older mines closed down when the newer and better equipped operations dumped their surplus output on the market. The erection of large central power plants and the consolidation of various groups of collieries in this region have both been in evidence during 1911.

In the Lancashire coal field, at Astley Green, the deepest colliery shaft in Great Britain is expected to be completed early in the coming year. This shaft will have a depth of 3360 feet.

During November, this year, much interest was aroused by the discovery of coal at Calvert, in Buckinghamshire, about 50 miles north of London. The geological conditions are here similar to those in Kent, yet owing to the thinning out of some formations, the coal

measures were found about 540 ft. from the surface, and three small seams have been encountered.

Coal Mine Bill

The coal mines bill for 1911, although a non-party measure, has been discussed even more than the Eight Hour act of 1908, which latter is now giving satisfaction. The chief discussion has centered around the use of electricity in gaseous mines, the abolition of naked lights, employment of female laborers on the surface, the provision of baths and wash houses and in connection with the rescue and ambulance equipment. The bill was not opposed in regard to its provisions for insuring the safety of mines and miners, but because of the increased cost which will devolve on some of the older collieries as a result of its being passed.

The Great Central Railway has just completed at Humber, a coal dock which is said to be the largest in the world. This dock has a capacity of 12,000,000 tons of coal per year on the basis of working 12 hours a day. Its eight hydraulic hoists can each handle 320 loaded cars a day. The cost of handling is much less than was heretofore possible.

Coal Output

The output of coal in 1910 was 264,337,786 tons, and for 1911 will probably exceed 270,000,000 tons. The number of workers employed in the mines has passed all previous records, and shows an increase over 1910. In 1851 nineteen persons were killed for every 1,000,000 tons of coal mined in Great Britain; in 1910 the death rate was 6.37 per million tons, whereas for 1911 the rate has been reduced below 6, there having been no serious explosions.

Chronology of Coal Mining for 1911

A record of important happenings arranged for ready reference. Also incidents and events of more than passing interest.

January

Jan. 3—Explosion and fire at the Sydney No. 3 mine of the Nova Scotia Steel & Coal Co. killed 8 men.

Jan. 4—Strike of 12,000 coal miners in Belgium was declared.

Jan. 10—A cave-in occurred at the Natia mine, Castro Urdiales, Spain; 190 men were entombed and 40 killed.

Jan. 20—An explosion and fire in the Casimir mine at Sosnowice, Russian Poland, killed 40 miners.—The Executive Council of the American Federation of Labor granted a charter to the Western Federation of Miners on the same basis as to the United Mine Workers of America.

Jan. 25—Explosion at the Hughestown No. 10 colliery of the Pennsylvania Coal Co. at Pittston, Penn., killed 6 and injured 5 men.

February

Feb. 6—Three men were killed at mine of Independent Coal & Coke Co., Kenilworth, Utah, by Greek miners on strike.

Feb. 9—Explosion at Cokedale Mine of American Smelting & Refining Co., near Trinidad, Colo., killed 15 men.

Feb. 17—Ninth annual meeting of western branch of Canadian Mining Institute.

Feb. 26—Fire was discovered in the Hazel mine of the Pittsburg-Buffalo Coal Co., near Canonsburg, Penn.

March

March 9—Lehigh Coal & Navigation Co., announced plan to build large electric plant at mines in Pennsylvania for high tension distribution of power over extensive area.

March 18—Explosion in Mine No. 16 of Missouri, Kansas & Texas Ry. Co., at West Mineral, Kansas, killed 6 men.

March 22—Fall of roof in Hazel Mine of Pittsburg-Buffalo Coal Co., East Canonsburg, Penn., killed 9 men.

April

April 1—Coal miners of Crows Nest Pass region of British Columbia and Alberta inaugurated strike.

April 3—U. S. Supreme Court upheld commodity clause of Interstate Commerce Law which prevents a railroad from owning stock in a coal corporation shipping over its lines.

April 7—Fire in the Throop mine of the Price-Pancoast Coal Co., Lackawanna County, Penn., killed 73 men.—Miners in British Columbia and Alberta agreed to submit wage dispute to arbitration.

April 8—Explosion at Banner mines of Pratt Consolidated Coal Co., Jefferson County, Ala., killed 128 men, mostly convicts.

April 11—U. S. Steel Corporation opened $5,000,000 coke-oven plant at Gary, Ind.

April 24—Explosion in Ott mine, No. 20 of Davis Coal & Coke Co., near Elk Garden, W. Va., killed 10 men.

April 28—Gypsy Grove breaker of the Pennsylvania Coal Co., at Dunmore, Penn., burned down, killing 2 men and seriously injuring four. The total loss was $50,000.

May

May 11—Fire at the Boston colliery of the Delaware & Hudson Co., Larksville, Penn., suffocated 5 men.

May 12—Mine tipple and buildings of the Pierson colliery near Jasonville, Ind., were destroyed by fire.

June

June 6—The 100th meeting of the American Institute of Mining Engineers opened at Wilkes-Barre, Penn.

June 19—Summer meeting of the West Virginia Coal Mining Institute opened at White Sulphur Springs, W. Va.

June 21—Dissolution of the E. T. du Pont de Memours Powder Co. was ordered on account of violation of the Sherman anti-trust act.

June 28—Summer meeting of Coal Mining Institute of America opened at Indianna, Penn.

July

July 6—Suit was filed by the U. S. Government against the Lehigh Valley R. R. Co. under the commodities clause of the interstate commerce act.

July 15—Explosion in the mine of the Cascade Coal & Coke Co., at Sykesville, near Du Bois, Penn., killed 21 men.

July 17—U. S. Government filed suit to compel separation of the Reading R.R. from the Reading Coal Company.

August

Aug. 1—Explosion in the mine of the Standard Pocohontas Coal Co., at Shannon, W. Va., killed 3 men.

Aug. 4—Suit was filed by the Government at Columbus, Ohio, against 6 railroads and three coal companies charging combination in restraint of trade.

Aug. 10—A four-deck cage dropped in the Krupp-Hannibal mine near Bocum, Germany, killing 25 men.

September

Sept. 8—Death of F. B. Robbins, for sometime president of the Pittsburgh Coal Co., and of the Monongahela River Coal Company.

Sept. 9—Merger effected at Cleveland of several independent steel companies into the Great Republic Steel Co.; Capitalized at $36,000,000.

Sept. 16—First-aid meets were held at Shamokin, Penn., Inkerman, Penn., and Trinidad, Colo.

Sept. 21—Death of John Bond Atkinson, president of Kentucky Mining Institute.

Sept. 30—H. C. Frick Coke Co. secured title to about 16,000 acres of coking coal from Pittsburg Coal Company, and Monongahela Consolidated Coal Company, the transaction involving about $18,000,000.

OCTOBER

Oct. 3—Fire destroyed the East Boston breaker of the Payne Coal Co., near Wilkes-Barre, Penn. Loss $100,000.

Oct. 5—Fire destroyed the Cuckoo mining plant of the South Chandler Coal Co. near Canon City, Colo. Loss $25,-000.

Oct. 6—Cage fell 80 ft. at the Peabody mine, Nokomis, Ill., injuring 8 men.

Oct. 10—Control of the Monongahela River Consolidated Coal & Coke Co. was absorbed by the Pittsburg Coal Co.—The 101st meeting of the American Institute of Mining Engineers opened in San Francisco.

Oct. 14—Reorganization of Peoples Coal Co., of Scranton, Penn. was effected.—Small fire occurred in the No. 9 mine of the Lehigh & Wilkes-Barre Coal Co. at Sugar Notch, Penn.

Oct. 18—Explosion in coal mine, Bardot, France, killed 26 men.

Oct. 20—Fire in the No. 8 mine of Brazil Block Coal Co. threatened the lives of more than 100 men.

Oct. 23—Explosion in O'Gara mine, No. 9 at Harrisburg, Ill., killed 8 and injured 10 men.

Oct. 24—The 14th annual convention of the American Mining Congress opened at Chicago.

Oct. 30—The National Mine Safety Demonstration opened at Pittsburg, Penn.

Oct. 31—The tri-district convention of the United Mine Workers of America, opened at Pottsville, Penn.

NOVEMBER

Nov. 9—Explosion in the Adrian mine of the Buffalo, Rochester & Pittsburgh Coal & Iron Co. near Punxsutawney, Penn., killed 8 men.

Nov. 10—Reorganization of the Pennsylvania Coal & Coke Co. was effected with a capitalization of $7,500,000.

Nov. 15—Freight reductions went into effect between Salt Lake City and Missouri River points.

Nov. 17—Canadian coal strike was settled by agreement signed at Hosmer, B. C., under which miners returned to work, Nov. 20.

Nov. 18—Explosion in mine of Bottom Creek Coal & Coke Co., at Vivian, W. Va., killed 18 men.

Nov. 20—Serious cave-in occurred at Scranton, Penn.—Coal Miners of British Columbia and Alberta resumed work.

Nov. 21—Hearing of Pittsburg-Lake coal rate case was started by Interstate Commerce Commission.

Nov. 28—Non-union Miner was shot at Louisville, Colo., in conflict with strikers.

DECEMBER

Dec. 4—Winter meeting of West Virginia Coal Mining Institute opened at Fairmont, W. Va.

Dec. 9—Explosion in Cross Mountain Mine No. 1, of Knoxville Iron Co., at Briceville, Tenn., killed 84 men, 5 entombed miners being rescued alive.

Dec. 11—Mid-winter Meeting of Kentucky Mining Institute opened at Lexington, Ky.

Dec. 12—Fire destroyed the top works of the Northern Central Coal Co.'s mine at Higbee, Colo.—The United Mine Workers of America balloted for their national officers.

Dec. 13—Eastern Ohio Coal Operators Association entered complaint before the Interstate Commerce Commission against three railroads, regarding freight rates to Lake Erie ports.

Dec. 18—American Federation of Bituminous Coal operators was organized at Chicago.

Dec. 19—Mid-winter Meeting of Coal Mining Institute of America opened at Pittsburg.

Dec. 23—Pit of Cross Tetley Coal Mine at Wigan, England, was flooded and the lives of 200 miners endangered.

Dec. 23—Six miners were killed by firedamp explosion at Teutoburgia colliery, Dortmund, Germany.

Dec. 24—Ohio and Pennsylvania operators declined to enter into interstate agreement with Illinois and Indiana operators.

Lake Tonnage for 1910 and 1911

According to the reports of the Hocking Valley docks at Toledo for the lake season of 1911 there was an increase of 175,455 tons over the amount handled by the docks in 1910. During the season of 1911 the docks handled 2,253,069 tons as compared with 2,077,614 tons in 1910.

The tonnage secured for the lake trade from the various mining districts in Ohio and West Virginia was as follows: Hocking district, 662,388 tons as compared with 666,218 tons in 1910; Kanawha & Michigan district, 886,405 tons as compared with 885,562 tons in 1910; Chesapeake & Ohio district, 651,-205 tons as compared with 492,101 tons in 1910; Kanawha & West Virginia district, no tonnage as compared with 12,239 tons in 1910; Coal & Coke district, 816 tons as compared with 13,449 tons in 1910; Norfolk & Western district, 50,781 tons as compared with 6367 tons in 1910; Wellston district, 1443 tons as compared with 1678 tons in 1910.

Coal and Coke Production in the United States

The following table has been compiled largely from data communicated by the several state mine inspectors, estimates having been made only where no such statistics were available, but in all cases upon the basis of good information:

PRODUCTION OF COKE IN THE UNITED STATES

States	1910, Short Tons	1911, Short Tons
Alabama	3,249,027	2,784,880
Colorado	1,190,901	946,284
Georgia	40,000	25,000
Illinois	390,000	375,000
Kansas	10,000	10,000
Kentucky	58,700	60,000
Missouri	5,000	5,000
Montana	58,200	52,300
New Mexico	510,000	450,000
Ohio	260,000	240,000
Oklahoma	30,000	30,000
Pennsylvania	22,875,000	19,403,750
Tennessee	240,000	210,000
Utah	141,050	140,000
Virginia	1,264,300	901,000
Washington	40,000	35,000
West Virginia	3,803,881	2,200,000
Other states	1,890,000	1,470,000
Total	36,056,059	29,338,214

PRODUCTION OF COAL IN THE UNITED STATES

States	1910, Short Tons	1911, Short Tons
Bituminous:		
Alabama	16,139,228	14,500,000
Arkansas	1,870,000	(*a*) 1,700,000
California	10,000	5,000
Colorado	12,104,887	10,075,861
Georgia	180,000	168,000
Illinois	47,064,500	(*a*) 48,411,000
Indiana	18,125,244	14,070,000
Iowa	7,260,000	(*b*) 7,574,919
Kansas	5,100,450	6,000,000
Kentucky	14,750,092	(*a*) 15,000,000
Maryland	5,009,600	4,500,000
Michigan	1,620,000	1,500,000
Missouri	2,980,700	(*a*) 3,000,000
Montana	3,050,000	(*d*) 2,913,397
New Mexico	3,616,665	3,440,022
North Dakota	385,882	395,000
Ohio	33,876,400	30,500,000
Oklahoma	2,840,000	2,800,000
Oregon	55,000	50,000
Pennsylvania	148,471,826	143,978,671
Tennessee	6,750,000	5,950,000
Texas	1,940,000	1,875,000
Utah	2,526,094	2,501,472
Virginia	5,750,041	5,490,000
Washington	(*b*) 2,490,047	(*b*) 2,371,481
West Virginia	59,690,300	60,500,000
Wyoming	7,469,452	7,027,000
Total bituminous	411,126.408	396,296,823
Anthracite:		
Colorado	70,586	64,379
New Mexico	8,000	(*a*) 8,000
Pennsylvania	82,591,649	86,823,686
Total anthracite	82 670,235	86,896,065
Grand total	493,796,643	483,192,888

(*a*) Estimated. (*b*) Fiscal year ending June 30. (*c*) Includes output of byproduct coke for Massachusetts, Maryland, Minnesota, New York, Michigan, Wisconsin. (*d*) Year ending Oct. 31.

The State of Indiana produced 18,125,-244 tons of coal in the year 1910, an increase of 4,433,155 tons, or 32 per cent. Of this total 17,249,785 tons was bituminous and 875,459 tons was block coal. The proportion of machine-mined coal was 10,888,367 tons, while 7,236,877 tons was mined by hand.

Issued Weekly by the
Hill Publishing Company
JOHN A. HILL, Pres. and Treas. ROB'T MCKEAN, Sec'y.
505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 6500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal is interested solely in matters relating to the fuel industries, and is designed to be a medium for the free interchange of ideas, the detailed description of coal-mining practice, and the expression of independent thought calculated to benefit both operator and miner.

Contents

COAL AGE

The Year 1912

The year just commenced is likely to prove an eventful one to coal men. Notwithstanding the much talked of hesitation and caution that is supposed to accompany each presidential year, there are good indications that the wheels of industry are beginning to turn a little faster, and it is posible the coming twelve months will be a period of marked prosperity.

Much heralded events seldom fulfil expectations. We have been told so often that 1912 (presidential year) is to be a time of lethargy in business due to the activities of politicians who desire to manufacture campaign material, that companies and individuals have prepared to withstand a siege, and repulse any attack that may be precipitated.

The past two years of curtailment in business expansion has healed many sore spots. Weak links have been eliminated and the commercial chain is stronger than ever before. Best of all we have entered a period of growth based on no less solid foundation than the provision of necessities for a rapidly increasing population. We have been taught that prosperity does not necessarily mean inflation, and that the utterances of a few rich men, who temper their words according to the state of their indigestion, cannot block the advance of the great body of industrial workers in America.

As a nation, we have unlimited natural resources, great visible wealth, and the willing hands and restless brains necessary to the development and increase of these valuable assets. Too many people mistake the meaning of an occasional drawing-back; they think it is a retreat, when it is but a preparation for another and greater leap ahead.

There has been no unusual advance in coal mining this last year, but the growth has been healthy. Innovations have been rare, however, more attention than usual has been given to perfecting present methods and to safeguarding the men underground. Prices have been rather unsatisfactory, but most operators have made both ends meet, and have brought their mines to a point of efficiency that will enable them to take advantage of the coming upward swing in business.

Legislation, especially with reference to employer's liability, will occupy the principal attention of coal-mine owners in 1912. It is also to be hoped that the year will witness a closer understanding between operators, not only in each district, but in each State. Competition is to be desired, but not a business war that will destroy all and fail to benefit even the consumer.

That consolidations are to be desired is proved by the distory of recent events. In 1904 and 1905, mines in several states were organized into a number of large companies and the beneficial result was clearly shown in an immediate bettering of conditions for the men; an improvement in mining methods, and the installation of modern machinery. The large companies were able to do things the small fellows could not attempt. Coal does not grow like fruit or grain and a pound wasted is a pound lost forever.

The talk of an extended strike in April should not be taken too seriously. The men will, of course, demand an increase in wages, shorter hours, etc.; however, there is little likelihood but that a fair settlement of differences will be reached. A strike will probably occur, but we hope and expect it will be of short duration, and be more in the shape of a temporary suspension that will injure no one.

By April 1, anthracite operators will be well stocked with coal. Mines in West Virginia, Alabama and other unorganized states will be able to supply fuel to meet any deficiency. Last and most important, coal miners are already receiving wages higher than ever before in the history of mining, and the slack between the "increase in the cost of living" and "an equal advance in wages" has been taken up. The chief labor leaders do not desire a serious conflict, knowing from late history that the time is inopportune, and the few minor officials who have assumed a belligerent attitude will probably be overruled.

Blackdamp

Many nontechnical words have an indefiniteness which serves a useful purpose for a while. And this commendable breadth of purview is often their complete undoing because they are liable later to be submitted to a narrow definition covering only a part of the ground they formerly covered, and thus their meanings become uncertain and obscure.

Those scientists who cater to the unscientific will try in vain to save the life of the word "blackdamp" as a specific scientific entity, though it might be left to live a long and useful life as a roughly generic word. It would be well constantly to revert to the fundamental meaning of the word. When a light is brought into an atmosphere in which it tends to expire or when a light in an unventilated atmosphere dulls in the air it has befouled, then blackdamp is present. The light deadens or actually dies out and the black darkness resulting causes the agent of that darkness to be termed appropriately "blackdamp."

This definition seems satisfactory. It is not technical and we need a nontechnical word which will cover the condition in a noncommittal manner, leaving it open to later investigations perhaps to determine what the nature of that particular blackdamp may be.

But blackdamp has not been permitted to remain the name of a flame-extinguishing gas *per se*. It is said that afterdamp, though it may dull or quench flame, is not blackdamp because carbon monoxide is present. So, according to some definers, we cannot distinguish blackdamp unless we know either the cause of its existence or its analysis and the term becomes needlessly exact and by that token less useful.

Some years ago blackdamp was declared a nontechnical term for carbon dioxide. A new use of the colloquial word was advocated as that word was less technical in appearance than that which indicated the definite chemical combination. But this twist in the recognized meaning of a familiar word nearly destroyed its value, because it was soon discovered that an extinctive natural atmosphere, which is a true "blackdamp," was always depleted of free oxygen whether rendered extinctive by the burning of lamps, the respiration of animals, or by the action of the mine walls.

So blackdamp has been twisted a second time to mean the mixture of carbon dioxide with an excess of nitrogen and its allied gases above their standard presence in common air. But this is clearly a technical definition; it does not represent an actual, existing gas nor even the full sum of the impurities of any actually existing gas, nor yet the change due to a certain single chemical or physical action.

It is a fact that "air" is still "air" and will be styled "air" though we now know it contains argon, krypton, xenon, helium and neon, as well as carbon dioxide and a little hydrogen. Nevertheless, the meaning of the word "air" is still definite because it includes all normal elements and gas compounds in an existing mixture—the atmosphere. But blackdamp only includes, we are now told, part of a mixture, to wit—carbon dioxide and nitrogen. Some would say moisture, if present, might be accounted a part of the blackdamp.

But some would declare that if methane is present, it cannot be considered a part nor can carbon monoxide or hydric sulphide. Yet others might even permit methane to be rated as blackdamp if the oxygen were low in percentage because a large percentage of methane extinguishes flame. All air vitiated by seclusion in the mines contains methane. And secluded air is the most common form of blackdamp, of which methane might under a new definition be said to be a part. If the word discussed is to be limited by all the artificial restrictions by which technicists would hedge it, it has become a narrow term, which only a technical man can use aright and which we may confidently assert many technical men of long training are grievously misusing. Hence the need to retain the word in its pristine value, neither adding nor subtracting from the original definition.

The word "blackdamp" as recently constrained, redefined and newly conceived by Dr. Haldane, is the excess of inert gas above that in normal terrestrial air. The suggestion occurs that we abandon the "blackdamp percentage" of Dr. Haldane and describe the natural air as containing 79.1 per cent. of inert gas; then graduate his tube for "testing blackdamp" so as to give not "blackdamp percentage," so called; but the "gross inert-gas percentage" in the air of the mine.

And this is advocated because it is a chemical device almost unheard of heretofore to group part of a constituent of a mixture under a different heading to that under which another part of the same constituent in like condition and of like qualities in the same mixture is grouped. And as it is true that the action of moisture and carbon dioxide by volume is not exactly equivalent to the action of nitrogen by volume, would it not be well to replace the words "gross inert percentage" by a more indefinite expression which would not indicate that the percentage was definitely indicated. We would suggest that this form of words should run "chemical index of inertia" or conversely "oxygen index," leaving the word "blackdamp" to express an atmosphere depressive of flame.

In conclusion it may be truthfully asserted that chemists of light and leading, do not know how to define blackdamp and will ascribe it to entirely different concepts in the course of a single article. Sometimes it will be an inert diluent of air. Sometimes it will be the diluted air itself. Even the context will be no guide. Nothing but the good judgment of the reader can follow the vagaries of the text.

Reversing Ventilation

Though the advisability of reversing the air current after an explosion or mine fire is a hotly debated question in this country, the English mining men seem definitely to favor that reversal. The Royal Commission of Mines as far back as 1906 considered the matter of such importance that it strongly recommended the provision at every mine, of means whereby the reversal of the air could be effected. The commission quoted several instances both of explosions and underground fires, wherein many lives might have been saved had it been possible to reverse the air without delay.

In this connection were instanced the fires at Hamstead, Whitwick, and the explosions at the Thornhill and Great Western collieries. Since then the explosions at the West Stanley and Whitehaven mines have strengthened the former conclusions. As a result, the new coal mines bill, which has just received the approval of both Houses of Parliament, requires that all fans shall be reversible.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Some Pennsylvania Questions

Blasting in Gassy Mine

Ques.—In what way is blasting dangerous in a mine giving off marsh gas? Explain fully.

Ans.—The flame of the blast may ignite a body of gas that has accumulated in some pocket in the roof or in a void place in the gob and escaped the notice of the fireboss. The explosion of this gas may stir up and ignite the dust and cause a disastrous mine explosion. A windy or a blown-out shot is always more dangerous in a gassy mine, because even a small percentage of gas greatly assists the ignition of the dust that is thrown into the air by the force of the blast, and the result is more apt to be a mine explosion. The firing of a shot in a gassy mine is unsafe unless the place is first carefully examined for gas, and reported safe.

Coal-mine Gases

Ques.—(a) What are the gases produced in coal mines? (b) Where are they to be found? (c) What are their relative weights?

Ans.—(a) The common coal-mine gases are marsh gas (CH_4), carbon monoxide (CO), carbon dioxide (CO_2), hydrogen sulphide (H_2S), and olefiant gas (C_2H_4). Hydrogen, oxygen and nitrogen, though occurring, at times, in mines, are not classed as mine gases; the two last named occur chiefly as air.

(b) In a well ventilated mine, outside of the return air current, these gases when present will be found at or near the place where they are generated. Marsh gas, being lighter than air, tends to accumulate at the roof or in rise workings at the face of steep pitches, where the air current is not sufficiently strong to sweep away the gas. Carbon monoxide is but a trifle lighter than air. It is principally found in close or poorly ventilated places, where shots have been recently fired or where combustion (oxidation) in some form has been taking place. Carbon dioxide, being half again as heavy as air, tends to accumulate at the floor or in dip workings, in swamps or other low places in the mine. Hydrogen sulphide is somewhat heavier than air, but does not occur in large quantities in coal mines. It would be found mostly in seams where pyrites occurs in the coal or the underclay, in low wet places or swamps where the air is dead. Olefiant gas never occurs in large quantity as a separate gas, but is often associated with marsh gas and found under similar conditions.

(c) The relative weights of these gases are shown by their several specific gravities. They are as follows: Marsh gas, 0.559; carbon monoxide, 0.967; carbon dioxide, 1.529; hydrogen sulphide, 1.1912; olefiant gas, 0.978.

Safety Lamps

Ques.—(a) What is a safety lamp? (b) Where and by whom should they be used?

Ans.—(a) A safety lamp is any lamp in which the flame is surrounded by a gauze or glass-and-gauze chimney in such a manner that it is completely isolated from the outside atmosphere surrounding the lamp.

(b) Safety lamps should be used at the working face and in all parts of a mine generating marsh gas in dangerous quantity. The condition of the mine with regard to dust, and the inflammability of the coal will determine the relative danger and the percentage of gas that may be considered as safe for open lights. In many bituminous mines 1 per cent. of gas, in the mine air at the face, would demand the use of safeties; while in hard-coal mines open lights are used with safety in 2 per cent. of gas; and 2½ and even 3 per cent. cause no particular alarm, in many cases.

Safety lamps should only be intrusted to those fully acquainted with their use and who know how to handle them. A safety lamp is very unsafe when handled in gas by an inexperienced person.

Improper Use of Safety Lamps

Ques.—What are the dangers arising from the improper handling and care of safety lamps by workmen?

Ans.—When a safety lamp is tipped or canted to one side so that the flame is directed toward the glass or gauze chimney, the glass may be cracked by the heat or the gauze become hot and the lamp pass flame. When the lamp is allowed to smoke continually or the gauze not thoroughly cleaned after each shift, or exposed to dust and dirt falling from roof and timbers, the mesh may become clogged so that the lamp is unsafe in gas. When a lamp is swung or allowed to fall or exposed to a strong current of air or the force of a heavy blast or carried rapidly against the air, the flame is liable to be blown through the gauze and ignite any gas that may be present. When a lamp is improperly put together, or any of its parts omitted or the lamp not properly examined, cleaned and trimmed in the lamp room, there is danger in its use in gas. When a lamp is exposed too long to gas or is allowed to flame badly, especially if moved quickly at the time, the flame may pass through the gauze.

Qualifications of a Fireboss

Ques.—What qualities, moral, mental and physical, are or should be considered essential in a fireboss?

Ans.—The moral character of a good fireboss must be unquestionable; he must be sober, honest, conscientious and fully trustworthy. Mentally, he must be observant and possess good judgment, alert to what is going on about him and quick to decide and act. He must be physically strong and possess in a marked degree the senses of hearing, seeing and smelling.

Safety-lamp Shields

Ques.—What are the advantages of having safety lamps shielded?

Ans.—The shield of a safety lamp is a small piece of sheet metal attached to one side of the lamp to protect the lamp flame better against a strong air current. The shield is sometimes fixed, but more often is movable and arranged to slide up and down, according to need. It has the advantage of giving added protection to the lamp when required without obstructing all of the light. It is very useful when traveling an airway with an unbonneted Davy or other lamp. The bonnet of a safety lamp is sometimes improperly called a shield.

Danger Signals in Mines

Ques.—When, where and by whom shall danger signals be used?

Ans.—The revised bituminous-mine law requires the fireboss to place a danger signal across the entrance to every working place or other place where explosive gas is discovered or any danger found to exist. The law requires that the superintendent furnish the signals, at the request of the mine foreman, and that they shall be uniform and of a design approved by the Chief of the Department of Mines and kept in good condition and distributed by the mine foreman or his assistant to points in the mine convenient for the use of the fireboss. Danger signals must be placed immediately on the discovery of the danger.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Is Carbon Dioxide Blackdamp?

Will you kindly explain what carbon dioxide is, and whether it is the whole of blackdamp or only a part. Please explain fully, as this question is the result of a discussion of five first-grade mine foremen and three firebosses located at the Eclipse mine, Elco, Washington County, Penn. I have claimed that carbon dioxide is not blackdamp, but is a part of it. I am taking COAL AGE.

CHAS. C. CRAWFORD.

Newell, Penn.

In early mining, when little was known of the nature of mine gases, and much less of their properties and composition, miners called all mine gases by the general term "damps," derived from the German *dampf*, meaning vapor. Later, as the different natures of the gases became known, the terms "firedamp; whitedamp; blackdamp; chokedamp, or stonedamp; stinkdamp; afterdamp, etc.," came into general use by the miner.

Still later, as mining conditions have been carefully studied by chemists and other scientific men it has been found that what miners have been calling *firedamp* is any inflammable mixture of gas and air that gives a flame cap. Before the use of the Davy the cap was observed on the open candle flame.

What was called *whitedamp*, in the mines, was found to be carbon monoxide (CO). The term *blackdamp*, likewise, was found to refer to any unknown mixture of gases that dimmed or extinguished a light and caused headache, nausea or suffocation.

While this mixture generally consisted largely of carbon dioxide (CO_2), it was found, in many cases, to contain much nitrogen and naturally the oxygen content was below the normal percentage in air.

Mining textbooks, based largely on the early writings of Atkinson, Fairley and other pioneers in mining literature, have been prone to describe blackdamp as carbonic acid gas (carbon dioxide, CO_2). The error of calling blackdamp carbon dioxide is therefore pardonable; but in reality the term, as used in the mines, refers to variable mixtures of carbon dioxide, nitrogen and oxygen, the two last-named gases being a residual atmosphere resulting from the various forms of combustion (oxidation), both slow and rapid.

Use of Brattice Cloth in Mines

What is brattice cloth and how is it used in mines? Is it used as much in metal mines as in coal mines?

New York. K. C. C.

Brattice cloth is any heavy canvas used as a curtain or a temporary wall or partition, in a mine airway or passage, for the purpose of directing the air current or deflecting it from its natural course, so as to ventilate certain rooms, headings, or void places that would not otherwise be reached by the air. The plain canvas or duck is frequently treated with tar, creosote or other preservatives to lengthen its life or render it incombustible. The canvas is furnished in rolls by mine-supply houses, or in larger quantities by commercial dealers in all kinds of asbestos cloths and packings, canvas, etc.

Brattice cloth finds its most important use in development work in mining, and in recovery work for reaching lost coal, or in mine-rescue work after a cave-in or an explosion. It is much used in driving prospect entries or headings or pushing rooms or chambers, for a time, ahead of the air.

The demand for brattice cloth is not as great in metal mining as in coal, only because the question of ventilation in metal mines is of minor importance. There is little or no gas, in these mines, that would prove a hindrance or a menace to the work.

Percentage of Grade

(a) I have two slopes, one dipping at an angle of 44 deg., and the other at an angle of 48 deg.; what is the per cent. of the grade in each slope? (b) How is the per cent. of grade determined for any angle of dip? (c) What is the angle of dip or pitch corresponding to a grade of 100 per cent.?

H. B.

Burgettstown, Penn., Dec. 4, 1911.

(a) The per cent. of grade, referred to the horizontal, in each slope, is as follows:

1. $100 \times \tan 44 \text{ deg.} = 100 \times 0.9657 = 96.57 \text{ per cent.}$
2. $100 \times \tan 48 \text{ deg.} = 100 \times 1.1106 = 111.06 \text{ per cent.}$

(b) The per cent. of grade, referred to the horizontal, for any dip or pitch, is always 100 times the tangent of the angle of inclination. If, however, the grade is referred to the pitch distance instead of the horizontal, as is the custom of some engineers, in steep pitches, the sine of the angle of inclination must be used in place of the tangent.

(c) To find the angle of dip or pitch corresponding to a given percentage of grade, referred to the horizontal, divide the given percentage of grade by 100, and find the angle whose tangent is this amount. For example, the angle of inclination corresponding to a grade of 100 per cent., referred to the horizontal, is the angle whose tangent is $\frac{100}{100} = 1$, or an angle of 45 degrees.

Ventilation of Airway

In an entry 7 ft. 6 in. wide and 6 ft. 8 in. high, the air is traveling at the rate of 120 ft. in 12 seconds. (a) What is the quantity of air passing per minute? (b) If the water-gage reading is 2.5 inches, what is the horsepower on the air?

Pittsburg, Penn. R. F. A.

(a) The sectional area of the airway is $7.5 \times 6\frac{2}{3} = 50$ sq.ft. The velocity of the air current is

$$\frac{120 \times 60}{12} = 600 \textit{ ft. per min.}$$

The quantity of air passing is then $50 \times 600 = 30{,}000$ cu.ft. per minute.

(b) The ventilating pressure due to a 2.5-in. water gage is $2.5 \times 5.2 = 13$ lb. per sq.ft. The horsepower on the air is then

$$\frac{30{,}000 \times 13}{33{,}000} = 11.818 \textit{ hp.}$$

Weight of Motor Required to Haul Trip up Incline

What weight of traction motor will be required to haul a trip of 10 loaded cars, weighing 3 tons each, up a grade, the tangent of the grade angle being 0.02619, and assuming a coefficient of friction of 0.03, and a coefficient of traction of 0.18.

South Fork, Penn. B. H.

The weight of the loaded trip is $10 \times 3 \times 2000 = 60{,}000$ lb.; and the weight of the motor car required, under the assumed conditions, is calculated as follows:

$$W = \frac{0.03 + 0.02619}{0.18 - (0.03 + 0.02619)} \times 60{,}000 = 27{,}230 \textit{ lb.}$$

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

A Speedy Coal Dump

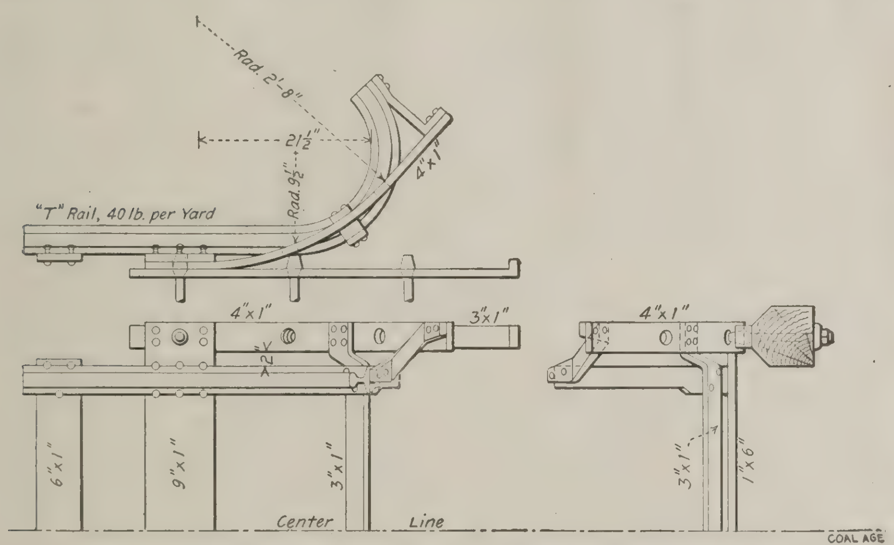
The readers of COAL AGE may be interested in the coal dumps much used in the Georges Creek field. The amount of coal dumped over them is remarkable. The dumping device, as shown in the illustration, consists of a movable platform which stops and supports the car as it tips over for dumping. There are two stationary guide plates on either side, outside the rails. These plates are of 3x1-in. iron, mounted on longitudinal timbers. Two lengths of 40-lb. T-rail are bent to form horns for engaging the car wheels on each side and just outside the rails, 1x4-in. roller bars are carried by the same plates, which act as spreaders for the rails.

In operation the carriage is held to its proper position by tapered studs which project from the guide plates and engage corresponding holes in the rollers. The force and the angle of the tip is so great that the car is pitched forward until the hind wheels leave the track, the car balancing on its front wheels. This complete tilt makes the car clean itself rapidly of all its coal.

The dumps are set close up to the switch of the track for empty cars, so that the car on being dumped immediately switches out of the way of the approaching loaded car. The distance of the heel of the rocker from the point of switch is 2 ft. 2 in. and the lead of the switch is 9 ft. 4 in. As much as 5403 long tons (6061 short tons) have been dumped in 10 hours over one tipple of this sort, and the dump has a capacity of at least 6000 long tons (6700 short tons) when the coal is kept ready on the sidetrack all day long. The following records have been made: Nine long tons per minute for 10 hours, 9¾ long tons per minute for two hours, 11 long tons per minute for one hour and 16.9 long tons per minute for short periods. The approaching grade is 3 per cent.

The mine cars, with normal topping, carry a net load of 2 tons 2 cwt. to 2 tons 6 cwt. (4704 to 5152 lb.) The dimensions of the cars are as follows: Length inside, 8 ft.; width inside at bottom, 25 in.; height inside, 2 ft. 10 in.; length over all, 9 ft. 6 in.; width outside at top, 36 in.; height over all, 4 ft. 4 in. Running to the dump at a good speed, they would jerk the tipple considerably were it high or long, but this is not the case at any of these tipples; they are all low and short. The tipple shown in the accompanying illustration (Elkhart mine) is in every way typical, though it happens to be one of the oldest in the district. I am indebted to R. A. Walter, chief engineer, Consolidation Coal Company, for this information and cut.

Chicago, Ill. R. O. BURT.



SPEEDY MINE-CAR DUMP USED IN THE GEORGES CREEK DISTRICT

TIPPLE IN GEORGES CREEK FIELD

Mine Workings Contiguous to Oil Wells

A gas or oil well may be considered one of the most dangerous features of its kind encountered in the operation of a coal mine. The ordinary dangers of the most gaseous mine do not compare with that which would result from workings tapping a producing gas well.

It is even possible that a serious accident could happen in working a mine some distance away from a well due to gas escaping through cracks, crevices or fissures in the coal seam. I have known oil to seep through pillars of solid coal when the nearest well was from 50 to 80 ft. away. It is also reasonable to assume that when drawing pillars, cavities or reservoirs of gas are formed which any disturbance of the overlying strata may force out with disastrous results.

In development work, when approaching a gas well, a pillar of solid coal equal to one-third of the thickness of the overlying strata should be felt for protection. In a mine, where pillars are being drawn, much more coal should be left and the same rule applies to a mine that is subject to a squeeze or creep. If the well is surrounded with old workings, I would suggest that a 12-in. hole be drilled into these workings at a distance not to exceed 15 ft. from the well; this will tend to relieve the rock pressure incident to the accumulation of any large reservoirs of gas. The pipes should be raised at least 10 ft. above the surface in order to allow any gas, which might be liberated from the workings, to readily escape.

No doubt we all can recall instances where havoc has been wrought in homes and business houses through a small leak in a gas line. So we can readily understand that it would not require the entire production of a gas well to cause a serious destruction of life in a mine. The gas pressure in houses varies from 2 or 4 oz. to 1 lb. per sq.in., while rock pressure, as recorded in wells in the McDonald and Oakdale oil and gas fields,

varies from 25 to 600 lb. per square inch.

The term rock pressure, as used in connection with oil or gas wells, signifies the force which the confined gas exerts in an effort to free itself. We have no guarantee that the casing itself will prevent the escape of gas, and even if it did, the life of the casing will not, in all probability, be equal to the life of the well.

To determine the size of pillars that may be depended upon, one must rely on his own personal observation and judgment. The following notes, however, should be carefully considered: (*A*) the thickness of the overlying strata; (*B*) the nature of this strata; (*C*) the character of the bottom; (*D*) the thickness and nature of the coal seam, whether hard and compact or soft and brittle, and (*E*) the inclination of the measures.

Narrow Work vs. Wide Entries—Relation to Operating Expense

I notice, in your issue of Dec. 23, page 354, a superintendent of mines, Marion, Ill., is interested in the opinion given relative to the driving of wide and narrow entries in mines; and the comparative expense of paying more yardage and getting less coal per yd. of narrow-work driven, or having to bear the lasting expense caused by roof falls and the timbering of wide entries, as long as the mine is a mine. Of course, much depends on the kind of roof you have to support. Some roofs will not allow you to drive anything but narrow entries.

I will state some facts that I have seen proven beyond a doubt, in regard to this matter. First, while top may be good at the start, it often gives way later, sometimes even years after the time of driving the entry. The cause may be due to a slight movement of the roof, owing to the removal of the coal in the rooms driven off the entry or the extraction of the coal in nearby workings. In some cases, there are peculiar roof conditions and the overlying slate or stone seems to give way suddenly from no apparent cause whatever.

Under such conditions as these, if the entries have been driven narrow, the expense of maintaining the entries is reduced to a minimum, as narrow-work always stands better than wide openings.

The Ohio-Valley coal seams are mostly all hard and the roof and coal, alike, are not badly affected by the action of air and moisture. Crossbars can be put overhead, in narrow entries, by hitching one end of the bar into the coal straight and making a sliding hitch for the other end. This method when it can be used saves much timber, as no legs, or only short ones at the most, are required for timber frames.

Narrow-work also does away with the heavy timbers that would be necessary on wide entries in order to avoid the setting of center posts in the entry, under the collars. Center posts not only increase the cost of timbering, but are dangerous to drivers and persons who must travel the entry. They are liable, also, to be knocked out and cause a heavy fall of roof in case a car jumps the track, which is by no means an uncommon occurrence in a mine.

My experience in overcoming a heaving bottom by driving narrow entries when opening a shaft mine, in a region new to me, at Cleaton, Ky., in 1905, was valuable. I found on investigation that quite a few of the mines in that region were troubled with heaving bottom, which necessitated the continual lifting of bottom on the roads and its removal from the mine. This work, in that region, was absolutely necessary.

It occurred to me that the difficulty could probably be overcome by driving only narrow entries with heavy entry pillars and making the room-necks about five times as deep as had been the custom there. The result of adopting this system was that I never had any heaving bottom. It saved the company many thousands of dollars. Another bad feature in regard to heaving bottom on entries is that it makes much mud in wet entries, and if the entry is dry it causes quantities of dust.

E. W. HOLT.

Central City, Ky.

Danger Periods in Mines

Regarding your recent editorial about "Danger Periods in Mines," will say that there are undoubtedly such periods both in a general and specific sense, but I cannot believe that seismic disturbances are responsible for the occurrence of mine explosions. It seems to me that the problem is perplexing enough without indulging in speculation as to whether the Courrières explosion caused the subsequent Formosa earthquake or whether the latter was responsible for the prior disaster in France.

I believe the reason why mine explosions, and especially dust explosions, are as yet so imperfectly understood is largely due to the fact that the laws governing them have not been established. A mine cannot be successfully ventilated unless the laws relating to mine ventilation are properly applied; neither can the danger from explosions be successfully averted unless the underlying principles regarding them are thoroughly known and understood. It may be said that dust explosions are erratic and subject to no law, but it can be readily proved that this is a mistake and that the occurrence and action of these explosions are controlled by well defined laws.

I do not know anything definite about conditions in the Briceville mine, but I am confident you will find when all the facts are known that the mine was not only well ventilated, but that draft facilities in it were exceptionally good, highly favoring what Mr. Hall terms "the advance (of air and dust) toward the center of the disturbance." According to the brief statement in the Dec. 16 issue of COAL AGE it appears that the air shaft was located in an ideal spot on the summit, nearly in the center of the mine; the main entries for at least 4000 ft. were exceptionally high (8 to 14 ft.); while at least one other opening to the surface besides the main entries and air shaft is mentioned and probably others exist leading either to the surface or into adjacent mines. Furthermore, I think it will be found that butt entries were more or less connected by rooms being driven through and that butt headings, not connected with others or with the surface or adjacent mines, will be found the least affected by the explosion.

The facts regarding conditions in the Briceville mine will also show that the conclusions presented in my article on "Iowa Mine Explosions," which you expect to publish in one of your January issues, are fairly sound.

JOHN VERNER.

Chariton, Iowa.

[If Mr. Verner will read carefully paragraphs 5 and 6 of the editorial he will see that we have merely drawn attention to the periodicity of both these phenomena, and their clearly evident synchronism in numerous instances.—EDITOR.]

Danger in Gassy Mines

For the benefit of some of the firebosses, I send you the following note showing the danger that may be caused by sudden fall of roof or open door in a gassy mine.

Suppose, for example, there is a current of 50,000 cu.ft. of air passing per minute, in a certain section of a mine, and the safety lamp shows ½ of one per cent. of gas on the return current, in this section. The quantity of gas given off is then $\frac{1}{2}$ $(0.01 \times 50{,}000) = 250$ cu.ft. per min. Suppose now a door is left open on the airway, so as to short-circuit the most of the air-current; or suppose a cave-in occurs on the main intake, so as to block the circulation and reduce the current to, say 3000 cu.ft. per min. This will render the return air-current highly explosive, and only the prompt and decisive action on the part of the fireboss will avert a serious catastrophe.

Red Ash, Va. A. T. WADE.

[The percentage of gas in the return air would be, in this case,

$$\frac{250}{3000} \times 100 = 8\tfrac{1}{3} \textit{ per cent.}$$

which is not far from the maximum explosive point.—EDITOR.]

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The new year has opened with the coal trade stronger than it has been at any time during the present season. More seasonable weather has appeared and brought with it heavier domestic consumption and a general improvement all along the line.

The market in the East has been rather quiet as a result of the holiday cessation of the industrial plants. While not active it has, however, been steady, with heavy movements on contract, and some demand for spot. The possibility of a shut down next April is being already anticipated in some instances by storing. Colder weather is reported from the South but as yet not of sufficient duration to effect conditions or prices.

The middle West has experienced it's first heavy blizzard of the season and there is a decided improvement in market conditions there. This trade has been on the verge of complete demoralization and the drop in temperature has appreciably strengthened the market, and checked any further shrinking in prices.

Trade in the Rocky Mountain states continues active and heavy tonnages are being moved. On the Pacific Coast the weather is mild and the market heavy.

New York

Business has not been as active this week as last. The market however, is steady as contract movement continues in excellent volume and although there is only a limited spot demand the tonnage moving on contract is sufficient to absorb the coal arriving at the piers without much delay. Railroad movement has been unusually prompt for this season of the year which has resulted in a good supply of coal at the piers so that shippers have been able to take care of their obligations with less difficulty than has often been experienced in the past, at this season of the year.

Strike talk is beginning to have considerable effect on consumers and shippers report that many of their customers are cognizant of the possibility of labor troubles in the spring and that those consumers who are in a position to stock up in anticipation of a suspension in the mining regions are making arrangements to store as much coal as is practicable. Marine transportation is still short and vessel freight rates are up.

Spot prices for steam coal f.o.b. New York are unchanged from those reported last week, West Virginias being quoted at about $2.40; ordinary Pennsylvanias $2.55@2.65; best grade Pennsylvanias $2.80@2.90. No accumulations at the piers of demurrage coal are reported.

Hampton Roads, Va.

The year closed at Hampton Roads unusually active in the coal business. Never in the history of the port has there been so great a tonnage put over the three coal piers. In round figures it may be reliably stated that ten million tons have been dumped at Hampton Roads during 1911. Official figures place it at 9,981,431 tons, divided among the three railroads as follows: Norfolk & Western, 4,393,353; Chesapeake & Ohio, 3,585,592; Virginian, 2,002,486. The optimism does not cease here, but it is predicted by those in close touch with large interests in the coal business that this figure will be boosted to 15,000,000 tons within the next three years. The exporting of coal from this port has risen from the experimental stage and is today a factor worthy of serious consideration. The prospects along this line for 1912 are unusually bright.

Owing to the customary let-up in mining in the New River Pocahontas fields between Christmas and New Years, the tonnage moving to tidewater is rather light. Nevertheless, the heavy shipments made in anticipation of the shut-down during the holidays is arriving and is being promptly dumped. There is practically no free coal at Hampton Roads this week, but that on hand is more evenly divided than it was last week. Prices are firm, possibly the best they have been throughout the year. Vessels appear to be more plentiful and rates are some easier.

Louisville, Ky.

This vicinity was visited by a belated cold snap within the past few days and, as a result, there is a better feeling among the dealers. Retail business improved, to an appreciable extent, although the increased trade was not sufficient to cause any change in the prices, which have prevailed locally for about three weeks. As it looks now, there will be little change before March, when a drop will come. In Louisville, and throughout Kentucky and southern Indiana the worst winter weather comes usually after Jan. 1. As a rule, however, most of the coal is ordered in advance of the new year, at the prices prevailing when the orders are given, and this accounts for the quotations fluctuating but little during January, February and early March.

One dealer is quoting Bannar lump at $3.25 per ton of 2000 lb. New River smokeless is quoted at $4.50 per ton and Pocahontas smokeless at $4.75. Reports from the mines are rather pessimistic, the producers insisting that the demand is not nearly what it should be at this time, and the prices hardly as good as last year.

Nashville, Tenn.

There is practically no change in the coal situation in this district. The usual dullness prevailed over the holidays, which together with the spring weather, made everything extremely quiet, although there is a good demand for screenings, which is always the case when orders are slack on domestic lump.

Prices are unchanged, as most of the shippers realize that cutting in order to get business, accomplishes little. It does not help moving the coal and has a tendency to place prices back to a low level.

The strike situation for the coming spring is being watched closely over the nonunion field, for it takes just such conditions as this every two years to keep a great many of our mine operators from going into bankruptcy.

Prices as quoted by the majority of the operators at present are as follows per short ton: 2½-in. lump, $1.50; nut, $1@1.10; pea and slack, 30@35c.; mine-run, 90c.@$1.

Chicago

An upward trend is noticeable in the Chicago market. A cold wave, accompanied by snow and a general cleaning up of surplus stock, have tended to strengthen the position of coal dealers and to check the recent fall in prices.

A closing down of the Illinois mines for several days also had its effect. Smokeless coal, which was at 80 to 90c. for mine-run, is now established on a basis of $1, and higher prices are looked for. Some observers predict that the same price for mine-run as is being obtained in the East—$1.20—will soon be secured. Lump and egg is firm at $1.75.

Prices direct from the mines in net tons to retail dealers and steam users on spot shipments are as follows:

Sullivan County	*Chicago*	*F.o.b. Mines*
Domestic lump....	$2.35@2.50	$1.50@1.65
Egg..............	2.30@2.40	1.45@1.55
Steam lump......	2.10	1.25
Screenings........	1.37@1.52	0.50@0.65
Springfield		
Domestic lump....	2.07@2.32	1.25@1.50
Steam lump......	1.92@1.97	1.10@1.15
Mine-run.........	1.82@1.87	1.00@1.05
Screenings........	1.32@1.42	0.50@0.60
Clinton		
Domestic lump....	2.12@2.27	1.35@1.50
Steam lump......	2.0[illegible]@2.20	1.25@1.45
Mine-run.........	1.82@2.02	1.05@1.25
Screenings........	1.42@1.52	0.65@0.75
Pocahontas and New River		
Mine-run.........	$2.95@3.05	$0.90@1.00
Lump and egg....	3.65@3.90	1.60@1.85

Coke—Coke is quoted at: Connellsville, $4.50@4.65; Wise County, $4.50@4.65; byproduct, egg and stove, $4.95; byproduct, nut, $4.55@4.65; gas house, $4.85.

Minneapolis—St. Paul

The coal business this past week has greatly improved over the previous weeks of this month. The weather turned cold, beginning on Christmas day, and has been hovering around the zero mark all week, ending with a good old-time blizzard. Abundant snow has fallen and has changed the Indian summer into real winter. Better sleighing could not be wished for. Wholesalers claim that the reason domestic trade from the country has been so slow this month is due to the fact that the dealer has been well stocked up, and, that the farmer has not been able to haul any coal home with him on his return from town, owing to the bad condition of the roads.

During the last week in December the average maintained was as much as any week during the record-breaking month of November. This indicates that the weather was largely responsible for the heavy movement into the country during that month. It is quite probable that the final figures will show that the tonnage for December, 1911, will be greater than for the same month in 1910, although the shipments will be less than for November. Dock men report that about 40,000 carloads of coal were removed from the head of the Lakes last month, and it is not probable that the December shipments will exceed 30,000 carloads. From now on till spring the market in this territory will be a weather proposition.

Prices on mostly all grades of coal have stiffened up and with continued favorable weather there is no reason why list prices should not prevail. Youghiogheny dock screenings are scarce, only two or three docks reporting any supply. Illinois prices are a great deal better than formerly. The dealer trade in the Twin Cities is reported as good and retailers are rushing out all orders while the sleighing is favorable, as teams are not any too plentiful.

The new briquetting plant of the Berwind Fuel Co., at the head of the Lakes, will soon be in operation and shipping briquets. They are also building an extension to their dock, which will give it a storage capacity equal to any of the other docks.

St. Louis, Mo.

With the first of the year came a change for the better in St. Louis prices. As a matter of fact, the demand has been considerably better than several anticipated, both for the city and country. A great many of the stocks that were run down are being replenished, and factory stocks that were slim, on account of the year-end inventory, are being laid in to the fullest capacity.

However, with this increased demand prices are not what they should be under present conditions. Two years ago this time, with the threatened strike, lump coal of Carterville grade sold for $2 per ton.

The chances are, however, that from this time on the coal market will continue to improve unless abnormal conditions set in. The winter thus far has been rather open and predictions are that from now on the weather will be more severe, and this, of course, will stimulate the demand. St. Louis prices are:

Franklin County	
Lump and egg................	$1.40@1.50
No. 1 nut....................	1.25@1.35
No. 2 nut....................	1.20@1.30
No. 3 nut....................	1.05@1.15
2-in. screenings..............	0.65@0.75
Carterville	
Lump and egg................	$1.25@1.35
No. 1 nut....................	1.15@1.20
No. 2 nut....................	1.05@1.10
No. 3 nut....................	0.90@0.95
Screenings..................	0.60@0.65
Mine-run....................	0.95@1.00
No. 1 washed................	1.60@1.75
No. 2 washed................	1.30@1.40
No. 3 washed................	1.20@1.30
No. 4 washed................	0.80@0.85
No. 5 washed................	0.40@0.45
Standard	
6-in. lump..................	$0.95@1.00
2-in. lump..................	0.90@0.95
3x6-in. egg..................	0.80@0.85
No. 1 nut....................	0.70@0.75
No. 2 nut....................	0.60@0.65
Screenings..................	0.40@0.45
Mt. Olive	
6-in. lump..................	$1.35
3-in. lump..................	1.25
3x6-in. egg..................	1.00
No. 1 nut....................	$0.85@0.90
No. 2 nut....................	0.75@0.80

There are no other coals coming into the market from the Illinois field, with the exception of Big Muddy, which is strong at $2.20 for 6-in. lump. High-grade coals from the inner district, such as Trenton, etc., are in good demand at about $2 per ton. Since the first of the year there has been a fair demand for anthracite of all sizes, principally chestnut, at the current circular.

There is also an increased demand for smokeless, which retails lump and egg at $6, f.o.b. bins, St. Louis. A fairly good volume of byproduct and gas-house coke is moving at $4.75 for the byproduct and $4.65 for gas house.

Spokane, Wash.

The prices for coal in Spokane and the surrounding territory have remained unchanged during the past week, and all indications are that there will not be any material changes until spring. The prices for the week ending Dec. 27 are as follows:

Kind	Wholesale	Retail
Rock Springs................	$7.20	$9.00
Owl Creek....................	7.20	9.00
Kirby........................	7.20	9.00
Carney.......................	6.70	8.50
Bearcreek....................	6.35	8.25
Roslyn steam................	5.25	6.25
Canadian steam..............	5.25	6.25

The cold snap, which has been prevalent for the last week, is drawing on the supply of coal in the local yards, but the supply is being continually replenished by shipments from the Canadian mines, and is equal to any demand that might come.

Portland, Ore.

Christmas trade was fine in all lines excepting fuel and the reason for the poor fuel trade was mild weather. Coal dealers look for no great volume of business until colder weather sets in. January, February and March are the coldest months in this territory. It is expected, however, that if cold waves sweep over the country for a couple of weeks during these months the rush for fuel will be so heavy that it will be difficult to fill orders promptly. The mild weather, while not making a heavy demand on the fuel stocks, has a tendency to make people forget that colder weather may follow and if it comes suddenly many will find their supplies short. A large number live here as in many of the larger cities, from a paper bag.

Foreign Markets

Great Britain

The labor outlook is regarded with much anxiety in view of the ballot of members of the Miners' Federation, of Great Britain, to be taken about Jan. 10. If further efforts to effect a settlement prove abortive and the result of the ballot is favorable to a strike, the men are to come out at the beginning of March, provided they observe their contracts and give one month's notice.

With the Xmas holidays at hand, the market is very quiet. Quotations are approximately as follows:

Best Welsh steam coal................	$4.20
Seconds............................	4.02
Thirds..............................	3.78
Best dry coals......................	4.02
Best Monmouthshire..................	3.78
Seconds............................	3.60
Best Cardiff small coal..............	2.16
Seconds............................	1.92

The above prices for Cardiff coal are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2¼ per cent. discount.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers, Affecting the Coal Industry

Washington, D. C.

An important joint meeting of the American Economic Association and the American Association for Labor Legislation was held here on Dec. 30, 1911, during sessions of the conventions of the two bodies. The U. S. Bureau of Mines had prepared an exhibit of mine rescue apparatus containing the familiar equipment usually on view at the Bureau of Mines itself and this was available for the inspection of the members and guests.

Secretary Fisher opened the meeting with a general discussion of the conditions under which the Bureau of Mines has been organized and the work it is attempting to do. He outlined the policy of the United States with respect to mining and the safety of miners in substantially the same way that he has on former occasions. Ex-President John Mitchell of the United Mine Workers who had been expected, was unfortunately detained away so that his address was not presented.

Diseases of the Mine

Dr. S. C. Hotchkiss discussed the general subject of occupational diseases, gave the results of work he has been doing for the Bureau of Mines on that topic, and reviewed such questions as diseases of the lungs due to damp and cold, and diseases like the hook-worm malady due to the presence in the soil of parasites which are probably propagated by faulty methods of disposing of excreta, etc. He then turned to the question of preventing such diseases and showed what had been done in Europe and what might be done here.

Dr. Holmes gave an interesting outline of the work of the Bureau of Mines and pointed out the particulars in which there should be an extension of activity. He said that the Bureau of Mines has been in existence one and one-half years. During that time its most important work has related to the causes and prevention of coal-mine disasters. This work concerns some 30,000 coal-mine officials, and more than 700,000 coal-mine workers, the majority of these latter being unfamiliar with the language, the laws, the institutions, or the policies of this country.

An Interstate Mining Commission

Dr. John H. Haynes, of Los Angeles, in his address, urged the establishment of an Interstate Mining Commission with power to enact and enforce regulations for the protection of the 700,000 coal miners now working in the privately owned coal mines of the United States, and to have direct charge of the coal lands owned by the nation, whether operated by the government or under private lease.

He showed that the national regulation in European coal mines had enormously reduced the percentages of fatalities in the last 18 years: in Prussia from 2.54 deaths annually per 1000 miners employed, to 1.94; in Great Britain from 1.49 to 1.29; in France, from 1.07 to 0.84; in Belgium, from 1.40 to 0.94; while under state regulation in the United States during the same period, the rate has steadily increased from 2.67 in 1895 to 4.86 in 1907.

The death rate in the several states, too, has varied all the way from 2.25, the average rate in Illinois for a term of years, to the frightful figures in the case of Colorado for the year 1907, when 21 out of every 1000 miners lost their lives in the single year, more than 20 times the rate of fatality for Belgium or France.

State vs. Federal Control

Continuing, Dr. Haynes said that the national government has saved the lives of thousands of railroad employees by enforcing the use of automatic couplers and other safety appliances; why should it not protect the lives of coal miners by enforcing in the case of mines producing coal for interstate markets such regulations as have been proven efficient in the saving of life? State regulation has failed wofully in the past; and it is altogether unlikely that it will improve in the future, for the following reasons: 1. Each state fears to impose regulations upon its own coal operators more burdensome than those to which their competitors in other states selling to common markets are subjected. 2. Each individual state cannot for itself make the scientific investigations, or maintain a body of experts, of the efficiency easily attainable by the national government. 3. State inspectors owing to political influences are notoriously less efficient than federal inspectors.

According to Dr. Haynes three European experts, invited by our national government to inspect our mines, agree that American mining, now so fatal, can be made as safe as any in the world, and at a small increase, if any, in the cost of production. Even if the last statement is called in question by coal producers, no broad minded and humane operator will object to efficient safety regulations, provided, of course, they shall apply equally to all of his competitors, including those of other states; so that the increased cost of production, if any, can be charged up to the general cost and added with other expenditures to the sales price.

Alabama

Birmingham.—The Pratt Consolidated Coal Co., with headquarters in Birmingham, will open an office in Mobile about Jan. 1. This company is one of the largest coal companies operating in the South, owning its mines and having a capacity of 10,000 to 12,000 tons a day. Offices have just been opened in Pensacola, Fla., also. The purpose of the establishment of these two branch offices is to develop the bunker and export coal business. The step is regarded as significant of the bearing that the opening of the Isthmian Canal is expected to have on the Alabama coal trade.

It is the general understanding that the underwriting of $2,600,000 of the proposed bond issue for the merged Alabama Coal & Iron Co. and Southern Iron & Steel Co., has been definitely arranged for, and that the way is now comparatively clear for the early announcement that the merger and reorganization plan is in effect. This will probably come when Cecil Greenfell returns from England.

Colorado

Denver.—A plan to unionize the 200,000 miners of Mexico was considered by the executive committee of the Western Federation of Miners which met here Jan. 4.

If the state land board incorporates a clause in its coal leases that was discussed recently and probably will be adopted, all danger of any combination of coal operators controlling the price of coal in the state will be forever done away with, for the clause will provide that the lessee shall sell all coal mined from state land at a certain price. With thousands of acres of coal still in possession of the land board, this clause will be sufficient to regulate the price of coal in every industrial center in Colorado.

Walsenburg.—The reports that a strike is imminent in the southern coal district are branded as being absolutely

false by B. P. Manley, of the Colorado Fuel & Iron Co. in a recent interview.

Central City—The coal dealers of Central City and Black Hawk are unable to get any coal from the Routt County fields, claiming that the Colorado & Southern R.R. will not bring up coal delivered to it by the Moffat road. Several cars have been turned over to the Colorado & Southern road, but that road has ordered them returned.

Illinois

Springfield.—Turning out 4,200 tons of coal a day, a force of 500 miners employed in mine No. 3 of the Superior Coal Co. at Bend, is straining every minute of the day to maintain that average and beat the record of a same amount for 13½ days held by miners of the Livingston mine at Livingston. The record established by the Livingston miners was made recently when for 13½ days the output of the mine averaged 4,200 tons a day. The Superior mine is one of the best equipped in the state and the miners are confident of being able to beat the record.

Returns from the recent state election of the Illinois' Mine Workers indicate that John Walker of Danville has been returned to the presidency of the organization by a large majority over Groce Lawrence of Herrin and Joseph Pope of Belville.

The new coal washer which the Chicago, Williamson & Vermilion Coal Co. has been building at Thayer is now completed and will soon be put in operation.

Peoria—The state mine inspector has strongly advocated a yearly service for the Fulton County mine inspector, because of the extent to which coal interests in this county have developed.

Belleville.—Work has been resumed by the Star Coal & Mining Co. and the St. Clair Coal & Mining Co., which operate mines south of Belleville. Both mines will employ a full force of men.

Edwardsville.—Parties whose identity has been concealed have been making large purchases of coal lands northeast of Edwardsville. Recently options on 2300 acres in Olive Township, Madison County, were closed. All the land lies at the junction of the Illinois Central and Chicago & Eastern Illinois tracks.

Indiana

Terre Haute.—Attorneys of the counties within the Indiana coal field have decided to appeal to the United States Supreme Court from a decision of the Indiana Supreme Court which held that the law imposing a tax on unmined coal is invalid.

The Indiana Coal & Land Co. recently filed options on about 500 acres of land in Otter Creek township. The price to be paid is $50 an acre if the options are followed by purchase of the coal rights.

Indianapolis.—In an effort to obtain a reduction in the price of anthracite coal, J. V. Zartman, secretary of the Indiana Manufacturers' and Shippers' Association, has authorized Alexander G. Cavins, attorney for the association, to file a petition with the interstate commerce commission attacking the freight rate on anthracite shipped from the Pennsylvania field to Indianapolis.

Brazil.—The American Coal Co. with headquarters in Brazil, has been buying land and taking options in the vicinity of Bicknell through its representative, Dr. Asbury of Clay City, until now it controls nearly everything between that city and the Baltimore & Ohio Southwestern R.R. at Wheatland. Most of this distance of about eight miles has been leased, but under some of the farms the coal has been purchased outright. As fast as the options expire they are renewed. The coal company will begin sinking a shaft on these lands early in the spring.

Kansas

Mineral.—It is rumored, from a reliable source, that the Mayer Coal Co. has purchased 120 surface acres and 200 acres of coal in what is known as the Wisewell tract a half mile northwest of town and near Mayer shaft No. 6. It is said the money consideration was $32,000.

Kentucky

Whitesburg.—It is given out in railroad circles that the Chesapeake & Ohio has completed arrangements for the early construction of a 25-mile branch line of road from Harold, on the main line of the C. & O., up Beaver Creek to the border of Letcher and Knott counties, to tap a rich coal and timber district owned by the Consolidation Coal Co., the Beaver Creek Coal Co. and the Northern Coal & Coke Co.

Sebree.—The sale of the mining property and coal rights of the Southern Coal & Transportation Co. at Robards was held by the Master Commissioner of Henderson County on Jan. 1. The coal and coal rights under 85.46 acres in Webster County and the surface coal and mineral rights under 64 acres in Henderson County and the coal and mining rights only under 7796 acres in Henderson County were sold.

The Kentucky River Consolidated Coal Co., composed of eastern capitalists, owning some 50,000 acres of choice coal and timber lands in southern Letcher and Perry Counties, along the line of the Lexington & Eastern R.R., makes the announcement that it will soon take steps looking to the development of the property. It will be necessary to build spurs out from the Lexington & Eastern R.R. to reach the property.

Barbourville.—The Harlan Town Coal Co., which is preparing to operate a mine on its property about a mile east of Harlan, in Harlan County, will soon have a town of its own in Kelly Bottoms. Many houses are already completed and others are going up or are contracted for.

Harriman.—The Harriman & Morgan R.R. Co., recently chartered, has elected officers as follows: C. E. Hendrick, president; J. N. Baker, vice-president; Robt. B. Cassel, secretary and treasurer.. Indications are that this road is to be built north from this city and will tap new and rich coal fields in the Lone Mountain and Brimstone Mountain sections of Morgan and Scott Counties. It is backed by the same interests that have constructed the Harriman, Knoxville & Eastern from here to Oliver Springs.

Missouri

St. Louis—The supreme court of Missouri has just handed down a decision which is of far more than local interest. When Gov. Hadley was attorney general of the state he instituted suit against the Missouri Pacific R.R. for violating that section of the state constitution which forbids a corporation from engaging in business other than that expressly authorized in its charter. Now Missouri's highest judicial tribunal decides that a railroad has a legal right to own coal mines or stock in coal mining companies, for the reason that "coal is necessary in the operation of trains." The court adds that "no one could contend for a moment that a railroad cannot buy a mine and dig its own fuel supply."

Moberly.—It is reported that Mine No. 11 of the Northern Central Coal Co. at Higbee, that some time ago sustained a great loss by fire will again be ready for operation in a month's time.

Ohio

Columbus.—Charges of discrimination in coal carrying rates were made Dec. 26 to the Ohio Public Service Commission by the Central Ohio Operators' Association against the Baltimore & Ohio and the Pennsylvania railroads. The association alleges that the tariffs of those roads for coal carrying from the Tuscarawas district are unjustly discriminatory and asks that the commission investigate at once and compel a readjustment.

Suit to foreclose a blanket mortgage for $834,500, given in July, 1901, was brought in the United States court Dec. 27 by the Bankers' Trust Company of

New York against the Pittsburg, Wheeling & Lake Erie Coal Co., the Wheeling and Lake Erie Coal Mining Co. and M. A. Hanna & Co., consisting of Dan R. Hanna, Robert L. Ireland and Matthew Andrews of Cleveland. The mortgage was given on 16,000 acres of Jefferson County coal lands and $200,000 was to have been paid by July, 1911. The Bankers' Trust Company asks that the Jefferson County property be disposed of to satisfy its claim.

Cincinnati.—The American Briquetting Co., which is a $1,250,000 Arizona corporation, was organized at Dayton, Ohio, recently, with C. L. McCrea, of that city, president and Thomas R. Morgan, of the Pocahontas Coal Co. here, as vice-president. The company will convert the lignite deposits of North Dakota into fuel briquettes at a plant to be built at New Salem, N. D. H. H. Hayes, the local representative, says that the company can produce the briquettes at $3.50 a ton at the mines, and will cut the retail price of coal in half in the Northwest.

Wellston.—An excellent grade of No. 2 coal, 3½ ft. thick, has been discovered on the Kessler farm, near Hawkes Bridge, east of here. A favorable report having been received from the chemist to whom the samples were sent for analysis a shaft will be sunk to the coal, with a view to placing it on the market.

Pennsylvania
(BITUMINOUS)

Bellefonte.—The coal mining operation of Atherton & Barnes, at One Mile Run, one of the most important in that section, has resumed work after a prolonged idleness. Upward of 150 men are again given employment.

Altoona.—Supreme Court Justice Bijur of New York has vacated an injunction obtained by the James Kerr Securities Co., holder of $500,000 bonds of the Pennsylvania Coal & Coke Co., to restrain the reorganization committee from executing a lease of the company's coal lands.

Indiana.—Development of the Brushvalley field which runs along the Blacklick near Josephine does not now seem as near at hand as it did a short time ago. Upward of $30,000 have been expended during the past year in drilling and prospecting and the tests have proved the coal to be some of the best in Indiana County. The sudden halting of proceedings is causing much comment, but several of the owners of the land, take the matter optimistically and fully expect final developments within a short time.

California.—Three men were burned to death in a poolroom and rooming house, at Daisytown, a mining hamlet, near here at midnight, Dec. 29. The men were employed by the Monongahela River Consolidated Coal and Coke Co., at Daisytown.

Latrobe.—Two miners are dead and four persons injured as the result of a dynamite explosion in a miners' boarding house near New Derry, Dec. 25. One miner, was blown to atoms. The explosion shook the town and was heard for several miles.

ANTHRACITE

Scranton.—Reduced freight rates on coal from the mines to points in New York state are scheduled to go into effect Jan. 20 on the Lehigh Valley, Philadelphia and Reading, and Delaware, Lackawanna & Western. Rates were reduced on the New York, Ontario and Western, Dec. 15, 1911.

Wilkesbarre.—For fear of damaging the county court house and the residences along the banks of the Susquehanna River, Mayor John V. Kosek has vetoed a bill introduced in Council to sell the coal underlying the river common.

Employees of the Hadleigh colliery of the Pittston Coal Co., at Sugar Notch, went on strike recently because they were paid by check instead of in money. Sugar Notch has no bank and the checks caused the men considerable inconvenience.

Pottsville.—The drainage tunnel which was begun nearly three years ago by the Lehigh Coal and Navigation Co., at a point a short distance above Nesquehoning Junction, and has been driven from there in a southwesterly direction, will soon reach No. 1 shaft above Nesquehoning, four miles from the beginning. Two sets of men are working toward each other, one from the entrance and the other from No. 1 shaft, and it is said that they are now only about 800 ft. apart.

Shamokin.—Preparations are now under way by the Philadelphia and Reading Coal Co. for driving a tunnel to cut the rich Buck Mountain vein, at the "Horseshoe" curve, near Glen Carbon. The Reading company has extensive coal operations all through that valley and the vein has been proven and followed for several miles east, along the Broad Mountain, showing a profitable thickness. The mammoth vein is to be worked from this locality as far as Frackville, a distance of eight miles.

Tennessee

Knoxville.—The regular monthly meeting of the Southern Appalachian Coal Operators Association was held Dec. 22. A feature of the meeting was a paper and discussion on workmen's compensation for accidents. The actions of certain law firms in connection with the recent Briceville disaster were vigorously denounced.

Texas

Strawn—After a suspension of work for nearly six months, the Mt. Marion Coal Mining Company has resumed work.

Utah

Salt Lake City—The Elk Coal Co., a Carbon County concern, which recently went into the hands of assignees, will probably be reorganized, according to an announcement made by the stockholders' committee, which has been investigating the company's affairs. The raising of $300,000 is contemplated to satisfy certain claims, and of this about $100,000 has been secured. The property is estimated to be worth several times the amount of the indebtedness. George Buckley, E. A. Lesser and L. Walker form the committee, which is looking after the interests of the stockholders.

Virginia

Bristol—The Virginia Iron, Coal & Coke Co., which has two large plants in Bristol, has made the largest coal contract ever made by a southern mining company. It has contracted to furnish the Boston & Maine R.R. with 66 cars of coal per day, for a period of five years. The amount involved is in excess of $9,000,000. Under the terms of the contract the coal is to be delivered to the tracks of the Boston & Maine R.R. in the city of Boston. The coal will be mined in what is known as the Toms Creek mines of southwest Virginia and will be shipped out over the Virginia & Southwestern and Norfolk & Western. This coal has heretofore been supplied from western Pennsylvania.

West Virginia

Morgantown.—The entire 200 ovens belonging to the Preston County Coke Company at Cascade are now in blast and the plant is working at full capacity. One hundred of the ovens have been fired during the past two months and between 300 and 500 men are now given employment.

There has been little change in the operations of the Elkins Coal & Coke Co. since No. 6 mine was opened.

Wheeling.—Ejectment proceedings involving more than 1000 acres of coal land in Webster and Randolph Counties recently came up before the United States circuit court of appeals. The Upper Elk Coal Co. and Christian Seybold both claim to own the property.

Weston.—Dr. D. P. Kessler is having a coal tipple built at his mines at Arcola and is making preparation to ship coal at an early date.

Canada

Montreal—The Dominion Coal Co. predicts a big increase in the output for 1912. Mr. Alexander Dick, the general sales agent says: "If everything turns out as we expect during the season of 1912, we will have a record-breaker, as the output will not be less than 4,000,000 tons, or a half million in excess of this year's figures." He also reports an improved situation at Springhill, where the output is between 30,000 to 35,000 tons a month, or around 400,000 tons a year.

Twenty-seven independent coal-mine operators of Alberta and eastern British Columbia voluntarily increased the wages of their workmen by 8 per cent., on Dec. 21, thus bringing the scale up to that of the mines employing union labor.

England

London.—The miners' federation has decided to take a vote on the question of national stoppage of the work in the mines, based on the question of a minimum wage. If a two-thirds majority of the members of the federation vote to stop work, the strike will be ordered for the end of February.

Another evidence of the labor unrest in the United Kingdom was manifested recently when 200 colliers, employed in the mines at Treorchy, Wales, went out on strike as a protest against the employment of non-union labor.

Personals

Frederick Gillmore, until recently with the Gulf Transit Co., has been given charge of the new branch office of the Pratt Consolidated Coal Co. at Pensacola, Fla.

C. M. Riker, formerly manager of the West Kentucky Coal Co. has been appointed assistant to W. B. Kennedy, president of the Nortonville Coal Co. at Nortonville, Ky.

Bart Murphy, for 20 years in the employ of the H. C. Frick Coke Co. and for a number of years foreman at the Standard shaft, has accepted the position of general inspector for all the mines of the Rainey Coal & Coke Co.

John Randolph Haynes of Los Angeles was recently appointed special commissioner, representing California, by Governor Johnson, for the purpose of investigating coal mines, and especially coal mine accidents throughout the United States. The commission issued by the Governor will furnish a sufficient entrée for Mr. Haynes in carrying on his investigations, and he will prepare a detailed report on the subject.

A committee of prominent mining and electrical engineers, which has been engaged in studying mining conditions in England, Germany and other countries, conferred recently with the officials of the Bureau of Mines, at Washington, D. C. Members of the committee are George S. Rice, chief mining engineer of the Bureau of Mines; Erskine Ramsay, of the Pratt Consolidated Coal Co., of Birmingham, Ala.; A. B. Jessup, of the Lehigh Valley Coal Co., of Wilkes-Barre, Penn.; H. M. Warren, of the Delaware, Lackawanna & Western R.R. Co., of Scranton, Penn.; G. B. Hadesty, of the Philadelphia & Reading Coal & Iron Co., of Pottsville, Penn., and John Bart, of the Berwind-White Coal Co., of Windber, Pennsylvania.

Obituary

George M. Davis, aged 67, one of the best known coal men in western Kentucky, died, recently, at his home, in Madisonville. Mr. Davis was manager of the St. Bernard mines, at Morton's Gap.

Capt. Levi Rinehart Doty, aged 64, for many years one of the best known men in Columbus, Ohio, died recently in Chicago, where he has been located for the past year. Capt. Doty was engaged in the coal business for nearly a third of a century. He served as president of the former New England Coal Co. and of the Northern Fuel Co., and also for a time as vice-president of the Pittsburg Coal Co. He was president of the National Tripoli Co. When he left the coal business, he became associated with the Ralston Steel Car Co. and for a year has been interested in the manufacture of cars at Chicago.

Industrial Notes

Announcement is made of the organization of the Bonnyman-Norman Coal & Iron Co., of Birmingham; James Bonnyman, president; James A. Norman, vice-president; A. H. Andrews, secretary. The new company will be the sales agent for the Brookside-Pratt Mining Co., and will handle coal and coke, and other industrial products in which the officers of the concern are interested.

The Ridgway Dynamo & Engine Co., Ridgway, Penn., announces the opening on Jan. 1, 1912, of a new district office in Room No. 1417, Oliver Building, Pittsburg. This move has been made in order that the company may better serve its many friends in the district and to facilitate the handling of its various well known lines of steam engines and electrical apparatus. J. F. Rodgers, who is a native of Pittsburg, and enjoys a wide acquaintance among the mine, mill and manufacturing interests of the city and vicinity, has been secured as local manager. Mr. Rodgers will be glad to welcome his friends and all friends of the Ridgway Dynamo & Engine Co. at its new office and to render any possible service on its behalf.

New Publications

FOURTEENTH ANNUAL REPORT OF LABOR STATISTICS FOR THE STATE OF VIRGINIA, 1911. 193 pp., 6x9¼ in. Public Printer, Richmond, Va.

Coal and coke production statistics are accorded three pages.

TECHNOLOGY AND INDUSTRIAL EFFICIENCY. Proceedings of the Congress of Technology, 1911. 486 pp., 6½x9½ in., illustrated. $3. McGraw-Hill Book Co., New York.

Some 70 pages are included in this volume and in all form a valuable and uptodate record of the present state of industrial science as well as a presentation of some of its problems and their probable solutions. The six sections into which the congress was divided are represented by papers on: "Scientific Investigation and Control of Industrial Processes," "Technological Education in its Relations to Industrial Development," "Administration and Management," "Recent Industrial Development," "Public Health and Sanitation," "Architecture."

ELECTRICAL ACCIDENTS IN MINES. THEIR CAUSES AND PREVENTION. Miners Circular 5. By H. H. Clark, W. D. Roberts, L. C. Ilsley and H. F. Randolph, 3 illustrations, 16 pp., octavo. Government Printing Office, Washington, 1911. Free on request.

It is a pleasure to commend this little booklet on the avoiding of electric shock and on the rescue work in connection therewith because we are sure that of all the people who have read and will read it, the authors will be the least appreciative. It is a book such as no technical men, immersed in advanced studies desire to write, but which they only undertake because they know that such books are needed by a public which cannot study and know the subject in a technical way. The authors are to be congratulated on the simplicity of their language, on their selection of essentials and on the fact that they have managed to write down a lot of practical information in a manner that will not fail to be of value to every miner or mine official who may read it. The booklet is for free distribution on request.

Trade Publications

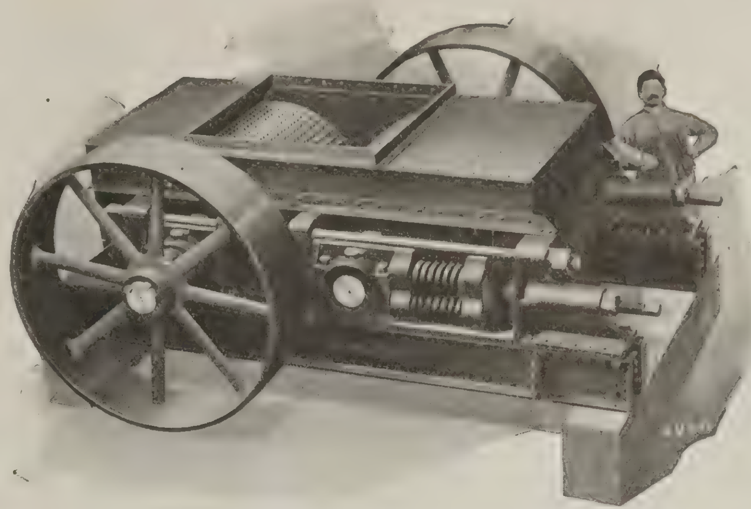
"LINK-BELT" CRUSHERS

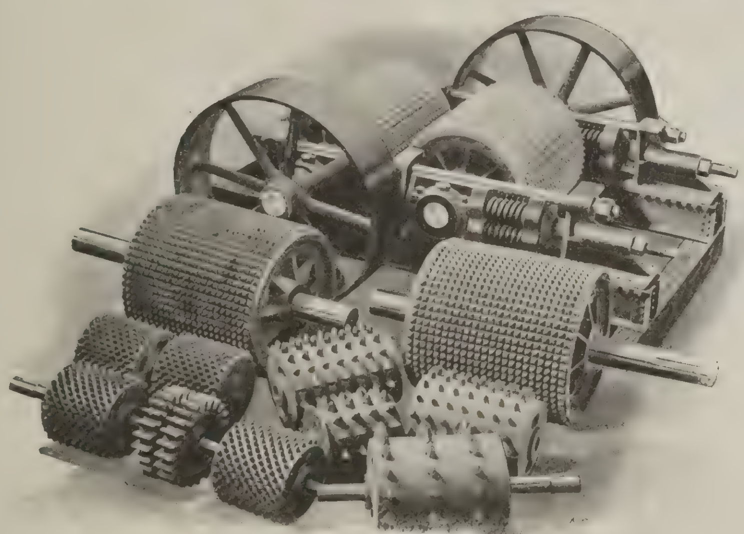
are made in various styles and sizes
to suit any conditions

The 54" x 54" "Link-Belt" Coal Crushers shown in the illustrations were built for the Vesta Coal Company. They are provided with our ≻FLINT-RIM≺ segmental rolls, which are driven by independent 84" x 20" pulleys.

Frame, 15½ ft. long
Capacity, 600 tons an hour



"Link-Belt" Coal Crusher — without receiving hopper



Group of "Link-Belt" Crusher Rolls
The crusher in rear is the one shown above, with hood removed. In the foreground is a pair of rolls for another. Both built for Vesta Coal Co.

The simplicity of Design, coupled with the substantial construction of "Link-Belt" Coal Crushers make them profitable investments for the Mine or Power House.

They guarantee——

Uniform Product
Maximum Capacity
Minimum Power to Operate

We Design and Build

Reliable machinery of every description for the efficient and economical handling of coal. Let our experienced engineers solve your coal-handling problem.

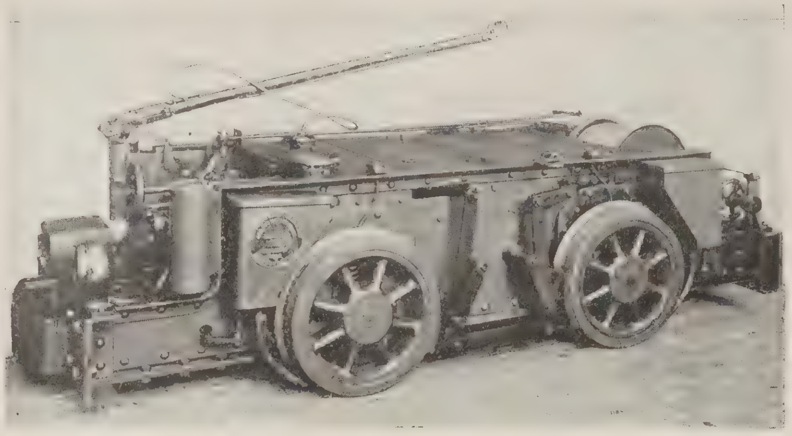
MINING MACHINE CUTTING KERF NEAR CENTER OF THICK COAL SEAM



More Power To You

whether you generate your own electric power or buy it from a central station, we can furnish the motor-generator set to do your electric locomotive work.

If you want lower mining costs

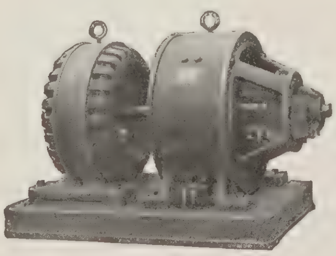
you can have them by using a Baldwin-Westinghouse Mine Locomotive in place of mules.

Let us help you reduce

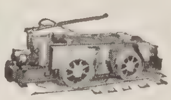
the time and trouble it now means to get out your coal. We have the figures to show that Baldwin-Westinghouse Mine Locomotives are the most efficient, reliable and strongest electric haulage engines on the market.

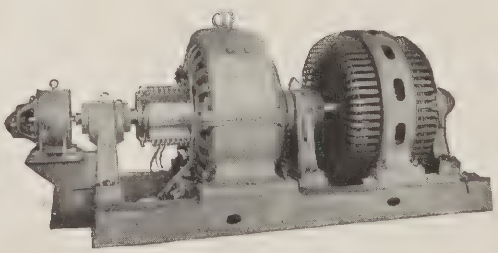
Expense

of installation can be more than made up in the first year or two's operation.



Motor-Generator Set
for Mines with one locomotive





Synchronous Motor-Generator Set
for Mines with several locomotives

Either company will give you full particulars

COAL AGE

Vol. 1 NEW YORK, JANUARY 20, 1912 No. 15

THERE are some questions pertaining to the operation of coal mines that are as old as the industry itself, and still have not been settled.

When emergency arises, and lives and property are endangered, it is immediate and definite action that's wanted, not discussion and conjecture.

Positive plans to combat every possible peril should be clearly in mind. Accidents that are foreseen are already half overcome. The man who completes a job in his head before he puts hand to it, is master in fact.

* * *

Mine fires furnish a problem on which we largely disagree. A case in hand that typifies the situation is indicated by a letter we received a few days ago from the manager of a large coal company.

He says: "At 8:15 on Wednesday morning, I was called to our No. 7 colliery because of a fire that had broken out in the last crosscut connecting the 10th West entry with its air course. On arriving at the shaft, I learned that all the men had gone to their places in the distant workings. The mine generates some gas, but is not considered dangerous. Open lights are used.

"At the shaft, hoisting of coal had already begun. I went underground immediately with the superintendent of No. 7 and was also accompanied by the superintendent of our nearby colliery, No. 4. The superintendent of this latter mine had been summoned because of his familiarity with the No. 7 workings, since it was he who had originally opened the mine and who had been in charge of its development up to within a year.

"On entering the 10th West entry, we encountered smoke and a high temperature, and were informed by our foreman and fireboss, who were directing hastily formed relay squads in fighting the fire, that the flames were likely to get beyond control.

"I called a hurried conference to determine the best plan of action in case we would have to isolate the fire. The superintendent and foreman of No. 7 advised placing the first stopping on the No. 10 main, or intake side of the trouble; the No. 4 superintendent and the fireboss at No. 7 were agreed that the first wall should be erected on the No. 10 air course or return side of the fire.

"A little later the flames were extinguished, but I have not forgotten the difference of opinion concerning the proper plan of attack. Therefore, disregarding local conditions that modify any specific rule, is it not possible to prescribe in general whether a fire at the face of a pair of entries should be sealed off, first on the intake, or first on the return side?"

* * *

Of all the serious problems that confront the coal industry, none is more deserving of immediate attention than this question of overcoming a mine fire. It is an interesting subject and one that cannot be dismissed with a wave of the hand or a sentence of speech.

We believe, therefore, that great good will result from a discussion of the problem, and we want every reader of COAL AGE who has an idea on the subject to write us his views.

Conditions differ today from what they were years ago. Rescue helmets enable us to work in smoke and gases—a feat heretofore impossible. Theories, like machines and men, wear out. To succeed we must fall in with time's changes. Those who swim against the current will go down in the eddy.

Were the superintendent and foreman at No. 7 right in their judgment, or do you agree with the opinion of the No. 4 superintendent and the No. 7 fireboss?

Coal Mine Ventilating Equipment

By W. M. Weigel *

Of the three classes of mechanical ventilators, the positive blower is least adapted and the centrifugal fan best adapted for use in ventilating mines. The second article of a series on mechanical ventilators.

*Associate professor of mining, Pennsylvania State College, State College, Penn.

Mechanical ventilators may be classified according to the principle on which they operate, as follows: 1. Positive blowers, which admit, confine and then displace a fixed volume of air at each revolution. 2. Centrifugal fans or blowers, which by rotating at a high velocity, impart a centrifugal motion to the air between the blades and thus tend to create a partial vacuum at the center of the fan. 3. Disk or propeller fans, which by means of revolving vanes or blades, set at an angle to the plane of rotation push or propel the air away from one side of the blades, thus creating a partial vacuum on the opposite side.

Positive Blowers

Positive blowers of either the rotating or reciprocating type are now seldom employed as mine ventilators. Their excessive weight for a given capacity, and the large amount of machine work required in their construction make the cost of machines having a large volumetric capacity prohibitive when compared with that of fans. Furthermore, they require skilled attention and careful adjustment, which increases their cost of operation.

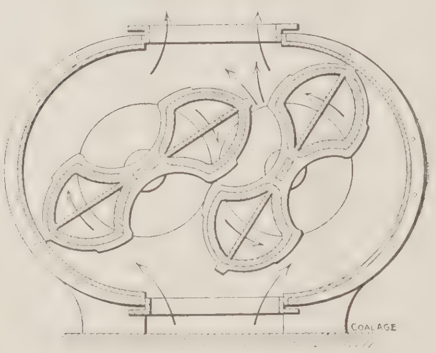

Fig. 1. Sectional View of Green Blower

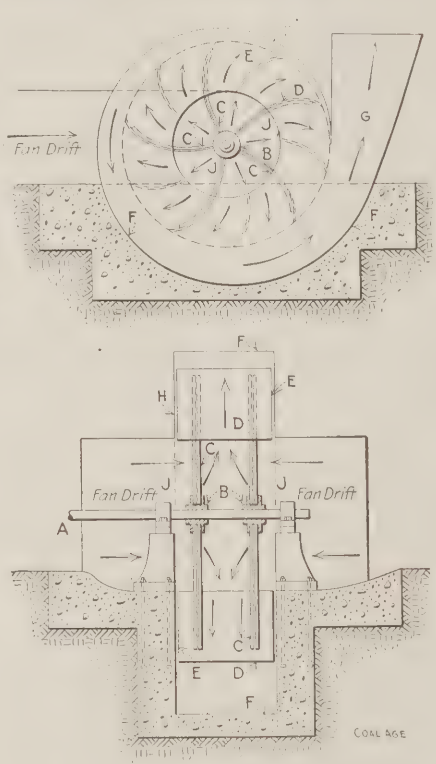

Fig. 2. Sectional Views of Centrifugal Fan

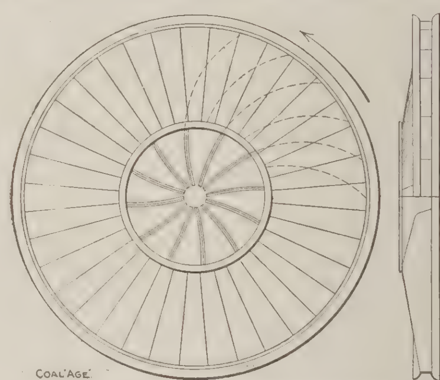

Fig. 3. Waddle Centrifugal-fan Wheel

Among the rotary blowers of this description are the Root, Connorsville, Green and Baker. The first three of these are quite similar in construction, and consist of two interlocking impellers, which revolve side by side, or one above the other, in an inclosing case without, however, coming into sliding contact with the sides of the case. Both the casing and impellers are made of cast iron accurately machined, and the fact that these surfaces must be mathematically true, adds greatly to their cost of manufacture. Perfectly made and designed impellers should roll together without friction, the points of each which may be in contact at any time always traveling at the same speed. Fig. 1 is a sectional view of a Green blower taken at right angles to the axis of the impellers; the arrows show the direction of rotation and movement of the air. At every half revolution, each impeller incloses the air between itself and its side of the case and discharges it through the outlet at the top. The impellers are geared together outside the case, preferably at both ends. These gears are accurately cut to reduce friction, insure quiet running and perfect uniformity of rotation of the two impellers. Fig. 4 shows a Connorsville blower direct-connected to a horizontal engine on the same bedplate.

The Baker positive blower differs from the Root type in having one main impeller which receives its power from the engine or motor and two auxiliary impellers or rotating valves, which admit the air during the intake part of the revolution and prevent its escape during the discharge period.

Reciprocating blowers are similar in construction and operation to blowing engines or air compressors, that is, the air is alternately drawn into and discharged from a cylinder by means of a piston, which may be driven by any form of motor, but is usually directly connected to a steam cylinder. However, their application is so limited as not to warrant further discussion.

All positive blowers are primarily intended to operate against pressures of 1 lb. or more per square inch. They do not however, discharge the air at a greater pressure than that necessary to overcome the resistance. But because they are designed to withstand and maintain such high pressures, their mechanical efficiencies are poor when handling the low pressure required for mine ventilation, which seldom exceeds 20 to 25 lb. per square foot. This fact is due to the excessive weight of their moving parts and their frictional losses.

Centrifugal Fans.

A centrifugal fan is shown in Fig. 2. There is a horizontal shaft supported by suitable bearings and between bearings the shaft is fitted with hubs rigidly keyed to it. From these hubs radiate arms or spokes to which vanes or blades are attached. The wheel is usually inclosed in a spiral casing with an opening in one or both sides at the center and one in the circumference. As the fan revolves, air is drawn in through the center opening. It then passes between the blades into the spiral casing and out through the opening in the circumference. If the fan draws air through its central opening from an inclosed space, such as a mine, it is said to be an exhauster, and if it delivers to an inclosed space through the opening in its circumference, it is then said to be a blower. The action of the fan is the same in both cases. The only difference being that

when exhausting the pressure within the inclosed space is less than, and when blowing greater than the atmospheric pressure.

Fig. 2 illustrates the general construction of a centrifugal fan and also shows the direction of the air currents, through one having an inlet on each side. *A* is the fan shaft; *B*, the hubs carrying the arms, and *C*, the arms which carry the vanes or blades *D*. The cheeks or side plates *E* are fastened to the ends of the blades and rotate with them. Their purpose is to stiffen the wheel and prevent the air from slipping around the ends of the blades as the fan revolves. The spiral casing *F* starts close to the circumference of the wheel and gradually enlarges until, having passed completely around, it widens out into the chimney or discharge opening, *G*. The fan shown in Fig. 2 is designed for exhausting. For blowing the discharge would generally pass off in a horizontal or downward direction. The sides plates of the spiral casing are shown at *H*, and the central air inlets at *J J*. Usually in an installation of this kind, the fan foundation forms the lower part of the spiral.

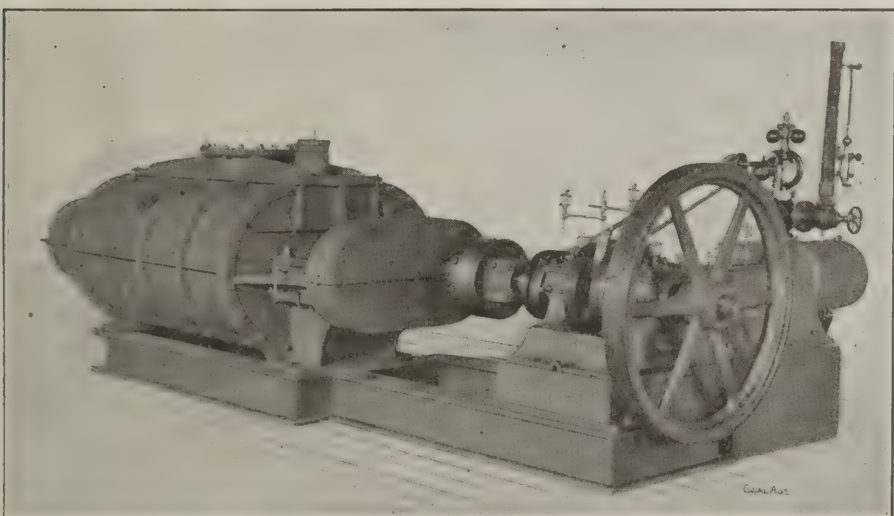

FIG. 4. CONNORSVILLE CYCLOIDAL BLOWER

The blades extend from the circumference of the inlet to the circumference of the wheel. There is no standard practice as to their shape and position. In some fans they are radial planes, in others they are convex toward the direction of rotation and slope backward. Some blades slope backward but have their tips bent forward into a radial direction. Others are planes but instead of being in a radial position, slope backward. In some extreme cases the blades are concave toward the direction of rotation.

The Waddle Type of Fan

A type of centrifugal fan used to some extent in England and Europe has no spiral casing, the air upon being discharged from between the vanes passing directly into the surrounding atmosphere. One form, the Waddle, is shown in Fig. 3, and consists of alternating long and short curved vanes fixed between and attached to two disks, one of which has a circular opening at the center for admitting the air from the mine. The fan drift must fit closely around this opening, and yet allow sufficient play for the free rotation of the fan. The solid disk is a plane, and the other disk is slightly coned, gradually approaching the flat disk toward the circumference. This reduction of sectional area is so regulated that the product obtained by multiplying the angular velocity at any point by the sectional area between any two vanes and the sides is a constant; which fact is supposed to keep the fan full of air. Beyond the tips of the vanes the disks diverge to such an extent that the area of the periphery at the edges of the disks is a little more than double the area at the tips of the vanes. This is done to reduce the velocity of the air as it is discharged into the atmosphere and increase the efficiency of the fan.

Waddle fans are made with large diameters compared to their axial length. The dimensions of a typical fan are:

Extreme diameter	36 ft. 4 in.
Diameter of tips of vanes.....	35 ft. 0 in.
Diameter of inlet............	13 ft. 6 in.
Width of vanes at tip........	1 ft. 1½ in.
Width at extreme periphery...	2 ft. 2¾ in.

In the latest forms the difference between the extreme diameter and the diameter at tips of blades is greater than in the above case. It will be noted that the long blades extend to the center of the fan; and that the portion of the blade between the fan center and the edge of the inlet is nearly radial in position, while the balance of the blade, like all the short blades, is curved backward from the direction of rotation. A few of the blades are shown by the dotted lines in the figure.

As the discharge from these open type fans takes place around their whole periphery, strong winds may interfere with their action at times. Further, the pressure is only one-half that developed by an inclosed fan of the same diameter running at the same speed as will be shown later. This, however, should have no effect on the mechanical efficiency of the fan. Tests of Waddle fans showing a mechanical efficiency of 65 per cent. have been published, but it is extremely doubtful if such results are possible. The error is, however, undoubtedly due to inaccuracy of measurements, especially of the volume and pressure of the air, and not intentional. It should also be noted that this type of fan is suitable only for installation as an exhauster, because it discharges around its entire periphery.

Machinery for Cutting Coal

An interesting paper on coal-cutting machinery, describing various types of rotary and percussive machines and comparing their advantages, was read by W. B. Shaw at a recent meeting of the Manchester Association of Engineers.

Mr. Shaw explained that the power employed for driving the coal cutter is compressed air or electricity, and though machines have been designed for driving by means of a haulage rope, no practical machine of such a type is at present working. The chief recommendation of compressed air is the absence of any danger of firing gas, or risk of possible shock to the machinemen; it is also a simpler apparatus and there is little danger of its being damaged by overloading. Its efficiency in power consumption is much lower than that of electricity.

The suspicion thrown upon electricity in connection with certain recent colliery explosions—a suspicion which was scarcely justified by the facts—has led to much serious thought on the risk in the use of electricity for coal cutting, and is likely to result in legislation imposing considerable restrictions along this line. Though this is leading to a considerable increase in the use of compressed air and has the appearance of being a setback to electrical cutting, it will no doubt be to its benefit in the end. It will result in still greater care and thought being given to the design of electrical cutters, with consequent improvements in those points which make for safety and at the same time reliability With a clearer definition of where electricity might be used, the colliery manager. when he decides to install electrical cutters, will do so with a feeling of greater confidence.

Any method of mining or handling coal that will materially reduce the percentage of slack without increasing the cost of operation is worth taking up.

Railroad Tracks for Soft Coal Mines

By M. L. Hyde*

The railroad-track plan is one of the first problems of a new mining plant. The various considerations that usually determine a layout of this kind are discussed together with several typical examples.

*Contracting engineer with the Roberts & Schaefer Co., Chicago, Ill.

While a great many articles are published from time to time regarding the surface arrangement of modern bituminous mines, only incidental mention is ever made in them of the railroad yards, and no definite information is usually given as to why the particular layouts are adopted. As the track plan is one of the first problems which confront the operator who contemplates building a new plant, the subject deserves more extended consideration.

Under present conditions nearly all bituminous mines are compelled to load from two to six grades of prepared coal in order to realize the maximum returns on the investment involved; and since every grade has a value in direct ratio to its size, it is desirable that each be loaded from the tipple or washer directly into its respective car, with as little handling as possible.

The Cost of Breakage

Particular attention is called to the fact that breakage is expensive to the operator in more ways than one, because not only is the average market value per ton mined reduced as the percentage of small sizes is increased, but also the first cost and the operating cost of the tipple itself are greater for the type which produces much breakage than for that in which the coal is handled in a thin uniform ribbon over shaker-picking tables and screens, from the time it leaves the mine car until it is lowered into the railroad car for shipment. A comparison of the cost of tipples having gravity or revolving screens, storage bins, etc., with that of the clean-cut, low structures, housing an equipment of shakers, will confirm this statement.

The practice of carrying bituminous coal to storage pockets in the tipple and subsequently drawing it out into railroad cars for shipment, should be avoided as far as possible. Coal loaded directly from a bin carries with it 5 to 15 per cent. of material, which has been crushed in the storage process to sizes below the standard, and, in order to hold the trade, this degraded material must be removed by rescreening the coal as it leaves the pockets.

If the full value is to be realized from these lip screenings, as they are called, they should be sent back to the main screens. For example, take a mine shipping the following grades: Three-inch lump, at $1.75 per ton; 1¼- to 3-in. egg, at $1.50 per ton; ¾- to 1¼-in. nut, at $1.10 per ton; and ¾-in. slack, at 75c. per ton. It would not be advisable to take all the 1¼-in. lip screenings from the stored egg coal and throw them into the slack, nor should they be put in with the nut coal. The proper method is to carry them all back to the screens and get as much nut as possible from the mixture. Attempts have been made to mix a small amount of the fines with the larger sizes, or to take egg coal from the run-of-mine and ship it separately while still holding up the value of both coals. With egg at $1.50 and run-of-mine at $1.20, it will readily be seen that this is a profitable subterfuge, but nevertheless one that will eventually bring the perpetrator to grief.

Loading Direct from Screens to Car

All this leads to the conclusion that each grade of coal should be laid directly from the screen preparing it into the car, thus requiring a separate railroad track for each size of coal. Now, while this is a desirable solution, yet, owing to surface conditions, it is not always practicable; in fact, seldom more than three to five tracks can be arranged for, in which case the three to five largest grades of coal should be loaded directly, and the remaining smaller sizes sent to storage bins.

Wherever bins are used it is advisable to build them as low as possible, in order to avoid bringing any greater weight than absolutely necessary on the coal which rests on the bottom. A satisfactory hoppered-bottom bin, having a capacity of 60 tons, or one car, can be built approximately 10x18 ft. in plan and 32 ft. high overall, with 14 ft. clearance from top of rail to discharge gate.

Yard Layout

The layout of tracks for railroad cars at a mine should provide in general for an empty storage yard above the tipple, leading to an independent system of loading tracks under the tipple, and thence in turn to a loaded storage yard below. Both the empty and loaded storage yards should accommodate enough cars for a day's run, requiring 1000 ft. of track in each yard per 1000 tons capacity of the mine. If the operation is large enough to own a switching locomotive, or to be served several times a day by the railroad, the size of the yard may, of course, be decreased, although it is usually not advisable to do so.

The empty yard should be laid off with a grade of 1¾ per cent. in favor of the empties, and should preferably have as many tracks as there are loading tracks under the tipple. In Fig. 1 is shown an empty yard with a scissors cross-over, allowing cars on any track in the yard to go to any track under the tipple. This affords a desirable layout, since in most cases all cars will be handled in a straight line. Moreover, it gives a maximum amount of storage room at a minimum distance above the tipple. One disadvantage of this yard, however, is that scales are required on every track, in case the cars must be weighed at the mine.

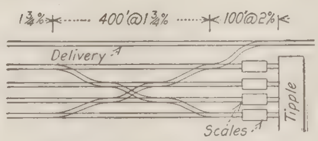

Fig. 1. Empty Yard

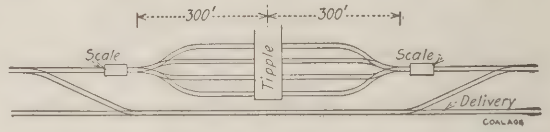

Fig. 2. Tipple Tracks and Scales

Layout for Track Scales

Where weighing is required, the layout shown in Fig. 2 is to be preferred. While this layout requires more room for a given number of cars and forces all but those on one track to round the curve and take the turnout, with a consequent risk of derailment and an increased amount of labor to start them off the scales, and also results in a more congested condition under the tipple, yet, on the other hand, it allows of bringing all the cars to one scale, and thus materially decreases the total cost of the yard.

The yard tracks should be on at least 12-ft. centers, and if the layout shown in Fig. 2 is adopted, may consist of from one to as many tracks as desired. The number will be governed by the ground conditions. Ordinarily, it is cheaper to grade for four tracks one-quarter of the total required length than for one track the full length, and time is saved on the part of the yard men in going after cars.

From a distance of 100 ft. above the tipple to a point 100 ft. below it, the track should be on a tangent, with a favorable grade of 2 per cent., this being required to insure that the cars will move forward readily a few feet at a time during the loading process. From this latter point the ladder should be run in on a 1¾ per cent. grade, and the loaded yard entered on a 1½ per cent. grade. After

a couple of hundred feet the grade in the loaded yard should be reduced to 1¼ per cent. It will be noted that in the arrangement shown in Fig. 2 only one empty and one loaded track scale are required.

Objections to Scales under Tipple

While at some mines the scales are placed directly under the tipple, this is not an economical method of weighing. In the first place, a separate scale is required on each track and in order that the empty car may be weighed with its front end under the loading chute and the loaded car weighed with its rear end under the same chute, the scales must be at least 75 ft. long. This is not only an expensive arrangement but it interferes with the continuous operation of the tipple since a fresh empty cannot be spotted until the loaded car has been weighed and pushed off the scale, thus involving an unnecessary loss of about a minute between each car, and also requiring an extra man.

In laying out the yards 80- or 90-lb. rails on 6x8-in. sawed oak ties with No. 7 turnouts and 12½-deg. curves should be used. This equipment will insure the grades remaining uniform and the curves will be sufficiently easy not to bind the cars. The ties should be spaced on 18-in. centers throughout the yard and their size should be increased to 6x10 in. wherever turnouts are located.

The track centers under the tipple should be 16 ft. between the lump-coal track and the next one inside, and 14 ft. between all others. The 16-ft. centers are required for the proper placing of the lump-coal loading chutes (especially where box cars are to be loaded) and for the tipple platforms, which are built on a level with the brakemen's step on the car to enable trimmers to pass from one track to another without loss of time and without danger.

The centers between the lump and the run-around tracks should be 14 ft. if a box-car loader is not used, and 30 ft. if it is. The run-around track should be so placed that the locomotive will never have to pass over the track scales and can deliver the empties and remove the loads with a minimum loss of time and without obstructing the ladder track.

Care should also be exercised in laying out the tracks, that cars carrying supplies may be switched onto a siding until unloaded and then fed over the empty scales to the tipple and used for coal if desired, all without interference with the flow of cars to and from the tipple.

Method of Handling Cars

One of the best methods of handling cars will be found to be as follows: The locomotive engineer in getting his trip of empties together places any supply cars there may be at the rear end, next to the locomotive, and then pushes the trip onto the run-around track and thence into the empty yard, after which he leaves the supply cars on their siding. He then travels over the run-around track to the far end of the loaded yard and pulls the loads away, or in some cases he pulls the loads from the rear end of the yard back onto the run-around.

After the cars have been placed by the locomotive in the empty yard, either one or two yardmen run them over the scales in trips of three to six and distribute them on the loading tracks, two or three cars to each track, riding each lot until the front of the first car is under the tipple loading chute, at which point the cars should be connected to a rope leading to a car retarder. This latter is an ingenious device, costing about $150, by means of which trips of from one to three cars are handled during the process of loading. It can be operated by the trimmer or dumper without requiring a man on the car.

The general idea of the retarder is that of leading a rope to the front car of the trip, and thence back to a small winding drum controlled by a band brake. With a grade of 2 per cent. under the tipple and all the brakes off, the cars will tend to run and thus maintain a tension in the rope. By easing up on the brake, the trip is allowed to move forward under the control of the operator until all three cars have been loaded, when the rope is detached and automatically rewound on the drum until the hook end comes back to the tipple and is attached to a second trip of empties. With a retarder for each track one man can control three car trips on two tracks at the same time or two men can control three car trips on four tracks. The yardmen jump the trip after it is unhooked and take it over the scales to the loaded yard. This system will allow of handling cars under a four-track tipple with only two spotters and two yardmen for a 3000-ton plant.

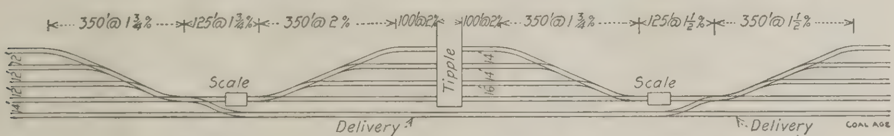

Fig. 3. Complete Track Layout, Empty and Loaded Scales

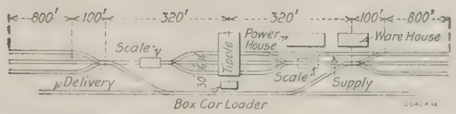

Fig. 4. Yard Plan

General Considerations

All railroad ties should be of sound, live white oak 6x8 in. by 8 ft. long, set on 18-in. centers. Six hundred and sixty-seven ties will be required per 1000 ft. of track. Switch ties are furnished by the lumber mills, already cut to suit the given switch, and should be of 6x10-in. material. For a No. 7 turn-out 2600 bd.ft. are required and for a No. 10 turnout 3200 ft. board measure.

Rails should be of either 80- or 90-lb. sections and 24 tons of 80-lb., or 27 of 90-lb. rails are required per 1000 ft. of track. Assuming average lengths of 30 ft. for the rails, 67 pairs of splices and 268 track bolts will be required per 1000 ft. The angle-type splice plate, such as the Bonzano, is to be preferred. Track bolts should be 4¾x⅞ in. with oval heads. They are furnished in 200-lb. kegs carrying 149 bolts each.

With 667 ties required per 1000 ft. of track, 2668 5½x9/16-in. railroad spikes will be needed, amounting to 7 7/10 kegs of 200 lb. each. The plain uniform spike with a clean-cutting wedge-shaped end will give the best results. No. 7 turnouts, complete with rigid frogs, point switches and stands, will cost about $100 laid. No. 10 turnouts, complete with spring-rail frogs, point switches and stands, will cost about $150 laid. The former can be used throughout the entire yard except at the cross-over to the main line, where the No. 10 should always be furnished. Stub switches should never be used.

A 44-ft. long 60-ton track scale for empty cars, set in a concrete pit, will cost approximately $1500. A 50-ft. 125-ton track scale for loaded cars, set as above, will cost $1750. These prices cover excavation, concrete, lumber, the scale and setting.

The surfacing of the yard will ordinarily be done with refuse ballast from the mine. All ballast should be crushed to pass through a 2½-in. ring and should be laid 6 in. deep under the ties. On this basis 250 cu.yd. of ballast will be required per 1000 ft. of track.

The advisability of having a yard laid out by competent engineers cannot be too strongly emphasized. Once a yard has been poorly laid out and graded, it means a great deal of money and lost working time to put it in shape.

A remarkable record was recently made by a puncher coal cutter made by the Hardy Patent Pick Co., of Sheffield, Eng. The work was done on a longwall face in a Durham colliery on a seam 3 ft. thick. The machine, which was handled by two men, started at 8:15 a.m. and finished at 3.20 p.m. The air pressure was from 45 lb. to 50 lb. per sq.in., and the length of the face cut was 47 yd., the depth 5 ft., and the maximum cutting speed was 180 sq.ft. per hour.

A Test for Coal Washing Economy

Special Correspondence

An apparatus is described by means of which a characteristic curve may be obtained for any coal. This curve shows at a glance what results may be expected from washing the coal in an effort to bring its percentage of ash within a certain figure.

Devices for mechanically washing coal make two products which are commonly termed coal and rock, although neither is entirely one or the other; and the object of the process is to leave in the coal exactly the amount of ash specified by the purchaser, while at the same time discarding a minimum amount of coal with the refuse.

Of the numerous fuels which we have had occasion to study, none has contained particles of either absolutely pure coal or of rock entirely free from carbonaceous material; the particles of fuel are all more or less mixed with schists, and their ash content increases progressively, from those which are most nearly pure coal to those which are practically all rock.

If Y is the yield in coal from the washing operation and X the ash content of the washed coal, we have:

$$Y = f(X)$$

This function varies considerably with different fuels and by determining its values we are able to tell exactly the greater or less amount of waste which is entailed by reducing the percentage of

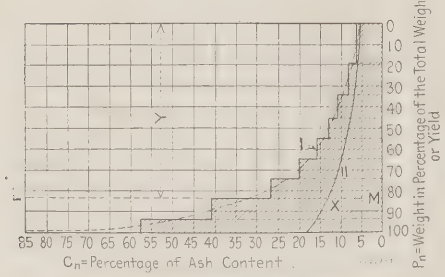

Fig. 1. Diagram for Deriving Characteristic Curve

ash and consequently enriching the coal.

These values can be obtained only experimentally; and in order to find them the apparatus which is here described was designed. It was constructed in the Van de Wyer shops, rue Haute, 17, Anvers, Belgium.

Description of the Apparatus and Method of Use

A bronze cylinder B of exactly 100 mm. (3.93 in.) inside diameter is plunged into a reservoir D filled with water, as shown in Fig. 2.

At the bottom of the cylinder a grate E, covered with a wire gauze, is held in place by two screws S S.

Having placed in the tube about 1 liter (61 cu.in.) of the coal to be tested, the cylinder is raised in the reservoir, by making use of the handles H, and then let fall quite rapidly; in this way the water flows in the direction of the arrows and the various particles of coal become stratified in accordance with their specific

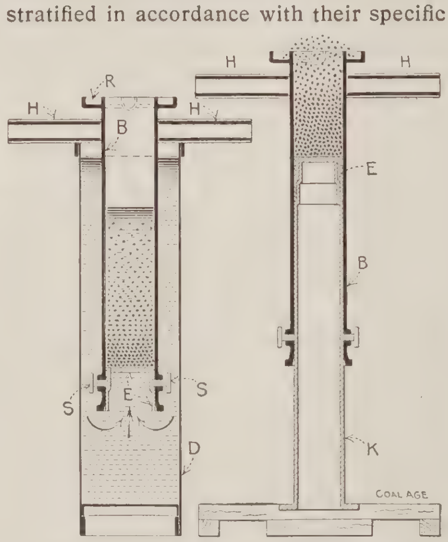

Fig. 2. Apparatus for Preparing Sample

gravities. For samples of very finely divided coal 30 to 40 strokes are necessary.

The deposit thus secured is made up of a series of elementary layers of weight P_n, Fig. 1., and ash content C_n. The apparatus, as we shall soon see, permits an exact division into perfectly horizontal layers practically as thin as may be desired.

Having separated the layers P_1, P_2 . . . . P_n, we dry and weigh them, and then determine their ash contents C_1, C_2 . . . . C_n.

The weights P_n of the separate layers are laid out as ordinates, and arranged in the order of their superposition, the total weight being made equal to 100. At the middle of the height representing the weight of each stratum we lay out, as an abscissa, a distance C_n proportional to its ash content, and we join the points obtained by a curve I, Fig. 1.

This curve gives the law of distribution of the ash in the sample of coal tested, and its area $\Sigma_0^{100}\ C_n P_n$ (represented by the shaded section of Fig. 1) gives the total weight of ash contained in the sample, of which the weight is 100.

The mean ordinate

$$X = \frac{\Sigma_0^{100}\ C_n \times P_n}{100}$$

is the ash content of the raw coal.

Separating the Bed of Coal

Now the industrial operation of washing coal consists in separating the bed of coal into two layers. The upper part is the washed coal and the lower part the waste.

Let $L\ M$, Fig. 1, be the plane of separation; then the upper part will have a mean ash content:

$$X_n = \frac{\Sigma_0^n\ C_n P_n}{Y_n};$$

the yield in the coal will be Y_n, and the loss due to the waste will be $(1 - Y_n)$

By varying the hight of the plane $L\ M$,

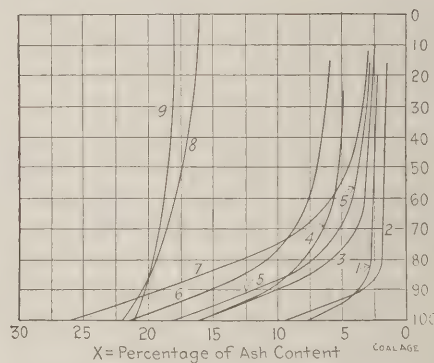

Fig. 3. Characteristic Curves of Various Fuels

a simple substitution gives the corresponding values of the general equation:

$$X = \frac{\Sigma_0^{100}\ C_n P_n}{Y}.$$

The locus of the point X is the required characteristic; and this curve $I\ I$ measures the inevitable loss which has to be sustained in treating a coal containing X per cent. of ash.

The apparatus has been so designed as to permit an easy separation of the layers. In order to do this the tube B is placed on the column K, the grate loosened by unscrewing $S\ S$ and, when B descends, it obliges the coal to fall into the gutter R. The screws $S\ S$ permit this operation to be stopped when deemed proper; in other words, to limit the height of each layer.

By using a cutter which is rested on the top edge of the tube, all the coal which projects is horizontally cut off and

Note—From "Revue universelle des Mines, de la Métallurgie," etc., Liège, Belgium, Article by R. A. Henry, director of the Hasard collieries.

transferred to a receptacle. The successive samples thus obtained are then dried, weighed and incinerated, each of them giving a point of the desired curve.

PRACTICAL APPLICATION

There are collected in the diagram, Fig. 3, a number of curves obtained for fine coals of ⅙-mm. size, coming from different places. It is noticeable that, for example, the samples Nos. 6 and 7, whose ash contents in the raw state (that is, for $Y = 100$ per cent.) are $X_6 = 21.3$ per cent. and $X_7 = 26$ per cent., respectively, will give the same yield in washed coal ($Y = 73$ per cent.) if we bring them to a common ash content of 8.75 per cent.

If it is required to enrich these products to a content of 7 per cent. ash, sample No. 6 will produce 47 per cent. yield and sample No. 7 will give 67 per cent. Thus we arrive at a result which at first thought would have been deemed paradoxical: No. 7, the more ashy in the raw state, leads to a loss almost twice as little as No. 6, to which incineration alone would have led us to attribute a superior value.

We note also that samples Nos. 8 and 9, which seem to be economical fuels, are not successfully cleaned by the process of washing. These curves vary with the different seams of coal, the size of the grains, the contents in pyrites, the presence of washing stones, etc Their interpretation, which is quite easily acquired, permits the engineer to draw conclusions unknown before the use of this method of investigation.

Longwall and Conservation

By Sim Reynolds*

Some interesting facts are brought out and seem to point conclusively to the eventual universal adoption of the longwall system. Comparisons are drawn between it and the room-and-pillar methods, showing enormous losses incidental to the use of the latter.

*Mine superintendent, Marianna, Penn.

With the gradual depletion of our surface coal, the necessity of working to greater depths, and conserving our supplies, the longwall system of mining is continually gaining more prominence. That more coal men are being converted to this system is not to be questioned, and if we may omit the faults, the arguments in its favor are overwhelming. It is not, however, the purpose of this article to cover up the bad features, nor to eulogize the good ones, but to set forth as clearly as possible a comparison of the present methods of working, and changes which might be advantageously made.

In fairness to the reader it should be stated that in Great Britain, which is the home of longwall mining, there were 1600 lives lost in the mines in 1910. A method of mining having such a fearful mortality in one year, is far from being what we would desire, and yet it may be the best attainable. Another detrimental feature which should not be overlooked is that of surface caving, although it may be here stated that the longwall system is no worse in this respect than others.

The success of any method is, of course, contingent on adhering strictly to the approved lines of procedure. The tendency is to leave undone those things we should do, and do those things we should not, and this human perversity is about the only vital feature connected with mining which does not change.

EVENTUAL ADOPTION OF LONGWALL ASSURED

It is becoming apparent that the next decade or two will see certain decided changes in mining methods. The newer generation will look back on the uneconomical systems of the old, and seek to remove the antiquated methods having such wasteful results. While longwall mining may not be the perfect system, it appears to embody the best methods attainable at the present time. The advantages of this system can be best shown by a comparison of the two methods on the same basis.

To the ultra-conservative who are not in sympathy with the impending change, we wish to call attention to the statement of an eminent consulting engineer, located in the Fairmont region in West Virginia, who is in direct touch with numerous mining operations throughout the United States. This authority says that many of the larger corporations, who can afford to make experiments, if thereby they have an even chance of making money in the end, are conducting certain portions of their work under all kinds and conditions appertaining to the longwall system. To prove these experiments takes time, and some day it is to be hoped an article will be published which will cover the more important of these essays into new methods.

NECESSITY FOR ITS ADOPTION

That there are some seams that it will be possible to work only by the longwall method is generally conceded and in the interest of the utmost possible conservation, there will probably some day be passed a sweeping edict covering all coal beds not yet mined. In the meantime, the companies which are trying out the different systems, will, upon the arrival of legislation on this subject, be in a position to say definitely just what they want.

The various conditions of its application would, of course, be determined by the local conditions, ellipse, circle or straight line being used, according to the usual circumstances governing the application of such rules. Whether it will produce the results extreme reformists would have us believe it will, is doubtful, particularly if the strata above it lay more than a good breaking distance in thickness. The opinion of the other side, who see in it nothing but expense and disastrous surface caves, is also equally doubtful.

For the sake of comparison of the results attainable by the different systems, a 1000-acre tract of land, with coal lying at a depth of 400 ft., will be assumed. By taking this depth as a basis, we give a conservative estimate of the possibilities of the longwall system on surface caving, which is about the only real fault that can be charged against it.

LOSSES BY ROOM-AND-PILLAR METHODS

According to all available statistics, a conservative estimate of the average amount of coal recovered under our present systems of working would be about 60 per cent., and less in many instances. The total tonnage on a tract of this size would be 9,680,000 short tons and 60 per cent. of this would give an approximate tonnage of about 5,800,000, which means the loss of nearly 4,000,000 tons of coal. At an average price of $1 per ton, it is readily seen that the nation is $4,000,000 poorer as a result. The glaring fact that our national wealth is $4,000,000 less than it might have been because of development of a comparatively small industrial operation according to established rules, cannot be ignored, especially when it is remembered that this is a loss which no mortal ingenuity can ever repair.

The miner who can look back on boyhood days spent sweating over a "Blow-George," furnishing insufficient air to a brawny South Staffordshireman as he delved in search of a possible thick coal pillar, may be of the opinion that this coal is not entirely lost. But by far the greater part is lost once the strata has broken, while on the other hand, such losses on longwall work are evident and more or less susceptible to remedy.

Surface Caving

In removing the entire seam some damage has perhaps resulted to the farmer, but not much, certainly, at a depth of 400 ft., and nothing beyond easy repairs. Where a total extraction has been effected on a 5-ft. seam having 100 ft. cover in certain of the Pennsylvania fields, the break has extended to the grass roots. Where this extraction has been several acres in extent and the break has been general over the entire area at once, it cannot be said that any appreciable damage has resulted. In this instance there was no packing whatever, as would ordinarily be the case in longwall workings. The conditions were simply 100 ft. of easily breaking roof with a clean fall of 5 feet.

Taking our previous example again, of 6 ft. of coal at a depth of 400 ft. worked by the longwall system and packed carefully, the result would by no means be so serious. Furthermore, it should not be forgotten that there are approximately 1000 square miles of coal in which the seams are 600 ft. or more below the surface.* At this latter depth it is doubtful if the strata would break to the surface, for it has been shown in the British mines that at a depth of 700 or 800 ft. work can be carried on successfully under the sea.

This proves conclusively that in average strata the highest fall reaches an apex far below that distance, and the miner who has had extensive experience in pillar drawing and is familiar with the quick oblique line that the ragged rock edges traverse toward a common juncture, will place the safety point much lower.

Comparison of Results

Turning again to our example of a 1000-acre tract, and assuming this to have been worked by the longwall system which has resulted in certain damage to the surface, a comparison of this surface damage, with the additional extraction obtained, may be made. Taking the mine on a royalty basis of 5c. a ton, the farmer has received $193,600 above what he would have received by the 60 per cent. pillar-and-room method of working. This amounts to $193 per acre, or about twice as much as the farm value of the land. It should also be remembered that the expense of tipple erection, compressors and power plants and the general surface arrangement of a mine opened to develop a track of 1000 acres, is the same for 60 per cent. extraction as for 100.

It is said that in longwall working continuous operation is necessary, in order to properly control the roof, but a little consideration will show that this applies nearly, if not quite as well, to room-and-pillar work, particularly when the mine contains water. The statement of a certain large Western operator, a man who is both practical and theoretical, may be taken, *apropos* of this. He has recently changed a number of his mines to the longwall system, and during a strike lasting over a period of about five months and a half, all of his mines were shut down. On the resumption of operations he had careful records kept of the relative cost of opening the longwall and the room-and-pillar mines. These records showed the cost of opening the room-and-pillar mines to be nine times that of the longwall.

Summary

Longwall mining provides an easier method of ventilation, a more thorough diffusion of explosive gases, a less quantity of timber, a ready disposal of refuse, and a certainty of no creeps or squeezes occurring to ruin the mine. In addition to this it has certain safety features, which should not be ignored, such as the impossibility of a general coal-dust explosion over an extensive area, since abandoned portions are practically closed and sealed off from the live workings, and the lessening of danger from a blownout shot, for, if rightly conducted, longwall requires little or no powder. The concentration of workings and the ease of superintendence should also be considered, for it is well known that in large mines there are portions in which the foreman seldom or never gets, while in longwall work this would not be true. Another item of considerable value is the large increase in the proportion of lump coal obtained, since longwall produces from 10 to 20 per cent. more lump than other methods.

When all the advantages of the longwall system are summed up, it seems remarkable that it has not been more generally adopted in the United States. That longwall will prove the ultimate and complete solution of all our troubles is not, of course, possible, but that it is the only method by which proper conservation of our coal resources can be obtained, seems to be beyond question. It is also thought that it will effect a material decrease in our death rate, but even if it only conserve our coal, it will prove its worth to the nation and the coal industry, and make the change a good one. The inverse ratio of price per acre with the number of acres left, will bring this idea more and more to the fore both in the minds of those who have to buy the coal lands and those who sell them.

New Type of Coal Cutter

Special Correspondence

The advantages of machine mining over pick mining are well known and appreciated. In general it may be said that coal operators have long since recognized the superiority of mining-machine practice to bunglesome pick methods. New problems are, however, constantly arising in regard to the selection of the machine best adapted to certain kinds of work and in connection with the designing of machines for meeting new and untried conditions. The Jeffrey-O'Toole Coal Cutter was originally developed for the mines of The United States Coal & Coke Co. at Gary, W. Va. It is the result of a suggestion of Mr. E. O'Toole, general superintendent of that company, and the co-operation of Mr. O'Toole and the engineers of the Jeffrey Manufacturing Company.

Fig. 1. Coal Cutter Ready to be Run to Another Place

Cuts Seam at Various Heights

The machine is built to cut a kerf at various heights, depending upon the

thickness of the seam, and is particularly useful in cutting thick seams where the presence of dust or gas limits the amount of explosive which can be used for each shot. In such cases the seam is cut at about its center and a small charge is sufficient to bring down one-half at a time. When small bands of impurities occur in the coal, the cut may often be so directed as to remove them, permitting the coal to be taken out without becoming mixed with the dirt.

This coal cutter can readily be removed to another room after finishing a cut. When the coal face is narrow, much time and labor is often consumed in moving machines of other types to and from their cutting positions, loading them onto trucks, etc. With this machine it is only necessary to connect up the driving chain, release the jacks, and move it from the room under its own power. In the illustration, Fig. 1, the machine is seen in position ready for removal to another place.

The room track should, if possible, be placed in the center of room, but if this is not practical on account of the space required for refuse, the end of the track may be curved so as to bring the machine to the center of the room when up at the face. The machine is mounted on a self-propelling truck, and as soon as the truck chain drive is disconnected it is ready for work. The runner immediately starts the motor, and while the cutter arm is swinging over from its position parallel with the track to the point where it starts to cut, the helper sets the jacks.

The room face is cut in a semi-circle 18 ft. in diameter, and the machine advances 5 ft. for each cut. The cutter arm is provided with a rachet feed which may be varied by an arrangement that causes the engagement of one or more teeth per stroke of the operating eccentric. The total time required to feed the arm in a complete semi-circle is from 7 to 28 min., depending upon the rate of feed used. The fast feed is always used to bring the cutter arm up to the coal and from the coal back to the center position. At the beginning of a cut a higher feed can be used than at its central part, when the arm is fully under the coal. The machine operator can readily stop and start the feed by means of a disc friction clutch, which also acts as a safety slip in case the machine encounters material that it cannot cut.

Construction and Operation

The construction and operation of the machine may be briefly described as follows:—The bed frame consists of a circular steel casting upon which is mounted the motor, all gearing and the cutter arm. This bed frame rests upon and revolves inside of a large steel ring, which forms the stationary frame. Riveted to this ring at three points, 120° apart, are cast-steel screw brackets, through which pass large adjusting screws. These screws are bolted to the steel top plate of the truck as shown in Fig. 2 and are fitted with adjusting nuts which are used to vary the height of the ring above the truck, and also serve to tilt the cutter-head to any desired angle.

The feed mechanism consists of a ratchet and lever operated by an eccentric on the main drive shaft. On the same shaft with the ratchet wheel is a worm which meshes with a worm wheel on the drum shaft. A disc friction clutch mounted on the drum shaft engages a rope drum, on which is wound a steel rope. One end of this rope is fastened to the hub of the drum and the other end hooked to the stationary steel ring.

Around the periphery of the circular bed plate are sheave wheels, over which the steel rope passes, and as the ratchet turns the worm, the drum revolves, winding up the cable and pulling the cutter-arm around in a circle. The disc friction clutch on the drum not only acts as a safety slip but allows a variation in the feed. As previously noted the ratchet is also arranged to engage one or more teeth at each stroke of the eccentric, thus permitting the feed to be varied at any time while the cutting is in progress.

The complete coal cutter is mounted permanently upon a steel truck which is provided with a self-propelling mechanism and an automatic reel for winding up and paying out the electric cable, as shown in Fig. 3. The machine can cut entries as well as rooms. When cutting entries, it is placed close to one rib and the cutter arm, starting in on the other rib, is sent under the coal until it cuts up to the rib by which the machine stands.

The Peat Industry of Russia

In a recent report of the Baku naphtha industry there are given some interesting data concerning the exploitation, development and consumption of peat in the central industrial district of Russia. As the price of liquid fuel has risen beyond the limit at which its use is satisfactory to industrial concerns, the question of replacing naphtha with other combustibles has come prominently forward, and it appears that for a number of purposes peat is just the fuel required.

The peat industry has by now secured an unquestionably firm position. In 1908 there were 73 firms engaged in the production of this fuel and they put out that year a total of nearly 52,000,000 cu.ft. These operations are chiefly in the departments of Moscow, Waldimir, Nizhni-Novgorod, Rjasan, Kistroma and Tambow. In 1907, according to the superintendent of the Moscow mining district, the central industrial region of Russia produced 181,500 tons of peat. In 1908 the quantity delivered was equivalent to 544,500 tons of hard coal, and the number of men employed in the industry was 17,000.

It should be mentioned that the processes of peat cutting and preparation used in central Russia, include practically none of the improved methods which have recently been brought into use elsewhere, and there is a wide field for future improvement and development.

In regard to the extent of the deposits, it may be said that the present workings are estimated as being sufficient to supply all demands for at least 40 or 50 years. There are, moreover, in this district many bogs which have not as yet been touched.

Ignition of Gas by Electric Lamps

Special Correspondence

Tests of portable electric lamps made at the Frameries experimental station, Belgium, show that under certain conditions all electric-lamp filaments ignite firedamp. Composition of the gas, size, shape and nature of the filament, and voltage of the lamp are governing factors.

NOTE—From *Annales des Mines de Belgique.* Article by Emanuel Lemaire, professor at University of Louvain and engineer, Frameries experimental station.

Portable electric lamps offer important advantages over ordinary safety lamps for lighting in gaseous mines. Their degree of safety is higher, since their luminous element has no communication with the mine air and therefore the danger of ignition does not increase with the proportion of methane and the speed of the air current. They have no delicate parts, such as metallic gauzes, which easily deteriorate and require careful daily inspection. They do not go out, and so the necessity of relighting inside the mine is avoided, a quality that is valuable in assisting the retreat of the miners after an explosion or mine fire.

They have, on the other hand, the disadvantage of being considerably heavier than ordinary safety lamps, and they do not indicate the presence of gas. However, this last inconvenience may be remedied by using at the same time a few ordinary safety lamps to serve as gas detectors.

An electric mine lamp well constructed, that is to say, strong without possible short circuits and one in which the sparks caused by opening and closing the circuit can only occur in an inclosed place, presents but one danger; that is, the breakage of the bulb. The existence of this danger, which may usually be remedied by surrounding the bulb with a protective envelop of thick glass isolating it from the surrounding atmosphere, has even been disputed, and contradictory opinions are offered on this subject.

We give in the present article the details of tests that have been made at the Government experiment station at Frameries, to clear up this point, to which the accident of July 7, 1905, at the colliery of Bois de La Haye, at Anderlues, had drawn particular attention.

The Ignition of Combustible Gases by Incandescent Metal Wires

It has long been known that incandescent metal wires may ignite combustible gases and that the temperature to which they must be carried to produce this effect depends on their diameter and the nature of the gas.

Davy showed, in fact, that an iron wire, 1/40 of an inch in diameter, if brought to a cherry-red heat, ignited a jet of hydrogen escaping into the air but did not set fire to a jet of ethylene. The latter ignites on contact with wire of 1/8 in. diameter brought to the same temperature. An iron wire 1/500 in. thick does not ignite hydrogen at less than a white heat; at a dark red it ignites a jet of phosphureted hydrogen. At white heat a wire of 1/40 in. diameter does not ignite firedamp; at a red heat it ignites carbon monoxide.

On the other hand, experiments of M. Hauser, professor of the School of Mines at Madrid, on the ignition of gas by incandescent electric wires, have given the following results:

1. Ferronickel wires, 0.3 mm. (0.0118 in.) diameter, did not ignite the most sensitive mixtures of artificial firedamp whether the metal was fused or not.

2. With a platinum wire, 0.5 mm. (0.0197 in.) diameter, gradually heated to a red heat, the ignition of a mixture of 7 or 7.5 per cent. of natural firedamp was produced six times without a miss and without fusion of the wire, which burned brightly at the moment the explosion occurred. With platinum wires of 0.2 mm. (0.078 in.) diameter and natural firedamp, there were two ignitions in three tests.

3. With soft-iron wires of 0.9 mm. (0.035 in.) diameter, the results are particularly interesting. When using a straight wire placed horizontally or inclined, or a curved wire turned sometimes upward, sometimes downward, natural firedamp of 7.2 to 7.5 per cent. was ignited six times out of 17 trials, that is, in one-third of the cases. The wire did not melt when there was no ignition, but melted in the cases where this occurred.

Influence of Shape of Filament

On the other hand, when using an inclined wire with a spiral in the middle, there were five ignitions in as many tests, and without fusion of the wire. In three of these tests the same wire was used three times successively and in a fourth test the twisted spiral wire ignited a mixture which had resisted a straight wire up to fusion.

4. As verification of the foregoing experiments, others were made with a steel wire of 0.6 mm. (0.0236 in.) diameter in pure artificial firedamp without obtaining an ignition in four tests where a straight horizontal wire 15 mm. (0.59 in.) long was employed, while ignition was produced by a wire 25 mm. (0.985 in.) long, incurved upward.

With an oblique wire coiled in three spirals, two trials were followed by explosions and in one of these cases the same gaseous mixture had already served three times successively for tests up to fusion of a straight horizontal wire 15 mm. long. This last experiment was repeated with the same result in natural firedamp.

It follows from these experiments by Professor Hauser that incurved wires or coiled wires ignite the firedamp more readily than straight ones, and that the susceptibility to ignition of gaseous mixtures is not the same with all metals.

Using iron wires of 0.05 to 0.35 mm. (0.00197 to 0.0138 in.) diameter, Messrs. Couriot and Meunier did not succeed in exploding firedamp mixed with air, even under conditions most favorable to explosion. Taken in connection with the foregoing experiments, these latter confirm the opinion that the finer the wires are the more difficult is it to produce ignition of explosive mixtures.

It is known that a combustible gas does not ignite in the presence of air unless brought to a certain temperature. In order that the ignition, when started at a point in the combustible gas and air mixture, shall be propagated throughout the bulk of the gas it is necessary that the heat liberated by the combustion of the first particles, which ignite in contact with the initial source of heat, shall be sufficient to raise to the temperature of ignition at least an equal mass of neighboring particles.

Proportion of Combustible and Size of Wire

If the proportion of combustible gases in the mixture is small and less than 6 per cent. for mixtures of air and firedamp, the mixture simply burns in the immediate neighborhood of the source of heat, forming around this an aureole more or less well developed, but the heat liberated by this combustion is too small to bring the neighboring masses of gas to the required temperature, and the ignition is not propagated.

Certain facts, and notably the fact that fine incandescent wires less readily ig-

nite firedamp than those of larger diameter, tend to prove that even in an explosive mixture, it is necessary that a certain mass of combustible ignite at one time in order to propagate the ignition. If this mass of gas is too small, the heat freed by its combustion is dispersed too rapidly in the surrounding medium to bring the neighboring gases to the temperature of ignition.

The larger the wire and the higher its temperature, the larger the quantity which takes fire on contact with it. It may be inferred from this that wires of large diameter ignite explosive mixtures more readily than finer ones.

During safety-lamp tests in gaseous currents, a sharp, needle-like flame is sometimes seen coming out of a crack of the chimney without igniting the surrounding explosive mixture. It is necessary to assume that this flame communicates the fire to too small a quantity of the explosive mixture to propagate the explosion.

The fact that spirally coiled wires more readily ignite the firedamp than straight wires seems due to the circumstance that the mass of combustible gas which traverses the coil formed by the wire is heated on all sides by the filament and by the heat set free in the combustion produced on contact with the wire, and thus the gas may more easily be brought to the temperature of ignition.

The influence of the mass of the combustible materials fired at one time by the initial cause of ignition has already been placed in evidence by the study of dust explosions. Resting on what has been said, we may foresee the possibility of firing combustible gases by the finest wires if only their temperature be sufficiently high. However, certain substances are liable to melt before the necessary temperature has been reached.

The experiments made at the Frameries station on incandescent lamps have shown that this is true. In fact, it has been possible to ignite explosive mixtures of air and firedamp by means of the filaments of all the lamps tried, by sufficiently raising the temperature, although these filaments were only a few hundredths of a millimeter in diameter.

Experiments with Carbon-filament Lamps

The experiments with carbon filaments were conducted with lamps of two and four volts. The bulbs, mounted on Sussmann lamps or connected to a battery of storage cells, with or without interposed resistance, and arranged to permit one or more elements to be put in circuit, were opened before their introduction into the test apparatus or else broken in the gaseous current itself by compression between the jaws of a vise. The experiments were made in gaseous currents of 0.5 to 10 m. per sec. velocity, containing 8 to 10 per cent. of methane.

The voltage and amperage were regulated on the lamp intact before the test; the voltage was measured at the contacts of the lamp, or, to speak more exactly, at the binding posts where were connected the large-diameter wires that brought the current to the lamp.

The electric current was cut off after each ignition of gas, to avoid the combustion or destruction of the filament during the time required for extinguishing the flames in the test apparatus; immediately afterward it was turned on again.

In a certain number of tests the temperature of the filament before rupture of the bulb was measured with a Féry absorption pyrometer. It is best to make some reservation on the subject of these temperature measurements, which were rendered difficult by the small size of the filaments with which experiments were made.

The experiments made by K. G. Falk in the laboratory of the Physico-Chemical Institute at Berlin and those at Columbia University, New York, have shown that the temperature of ignition of combustible mixtures varies with the composition of these mixtures. So it is that a mixture containing 50 per cent. of hydrogen and 50 per cent. of oxygen takes fire at 788 deg., while a mixture of 80 per cent. hydrogen and 20 per cent. oxygen ignites only on reaching 878 deg. A mixture of 66 per cent. carbon monoxide and 34 per cent. oxygen ignites at 875 deg., but a mixture of 50 per cent. carbon monoxide and 50 per cent. oxygen ignites only at 915 degrees.

For mixtures of air and gas, the experiments carried on at Frameries as a preliminary to the tests on the explosives, have shown that the compositions of greatest inflammability contained between 7.5 and 8 per cent. of methane. It is this composition which was used in the majority of the tests to which the carbon-filament lamps were submitted.

These tests have shown that it is possible to ignite explosive mixtures of air and firedamp by the incandescence of a carbon filament; numerous gas ignitions were obtained without rupture of the filament.

It is therefore learned that an incandescent carbon filament may ignite firedamp, and that this ignition is not necessarily produced by a spark resulting from rupture of the wire.

Conditions Affecting the Experimental Results

Contrary to what might be supposed, the combustion of a carbon filament in air sometimes takes several minutes; the time necessary depends on the temperature to which it is brought, but this time is always appreciable.

The temperature to which the filament is normally submitted varies with the type of lamp; at least such was the case with the low-voltage lamps used for the experiments. Further, some lamps of the same type have a greater electric resistance than others and the temperatures of their filament may therefore differ for the same voltage applied to their binding posts. This is a primary cause of failure to obtain absolute agreement in the results.

There is also another cause of discrepancy. At the moment when the air enters the bulb, a cooling by convection is added to the cooling by radiation, and the temperature of the filament instantly falls. When we close the jaws of the vise slowly and carefully, the bulb is sometimes broken into only two or three pieces. In one test it was seen that these fragments, held by the jaws, remained so well in contact that the flame could not pass out. It may be inferred from this that in certain cases the exterior air may enter the bulb and lower the temperature of the filament before the cracks between the fragments are of sufficient size for the explosion to pass out. The manner in which the bulb breaks may, therefore, have an influence on the results.

The temperature of normal operation of the carbon-filament lamps for a consumption of 3.5 watts per candlepower is valued at about 1400 deg. by certain authors and about 1600 deg. by others. The U. S. Bureau of Standards fixes this temperature at 1800 or 1820 deg. C. These differences arise seemingly from the difficulties presented by high-temperature measurements in general, and especially in measuring the temperatures of incandescent filaments.

Temperature of Filament and Rapidity of Gas Ignition

When a bulb is broken in a gaseous medium, or when the current is passed through the filament of a lamp broken in advance, we obtain:

1. Combustion of the filament without ignition of the gas.
2. A retarded ignition, which sometimes takes place after several seconds without the wire necessarily having been ruptured.
3. An immediate ignition.

After a series of immediate ignitions, there are sometimes produced one or more retarded ignitions; sometimes also the filament burns up without lighting the gas. On the other hand, the retarded ignitions are sometimes followed by immediate, or less retarded ones.

The tests on bulbs opened before introduction into the testing apparatus show that by greatly overvolting the lamps we get immediate ignitions; by overvolting them less, we get retarded ignitions, and by not overvolting them at all, or by letting them fall below the normal voltage, the filament more often than otherwise breaks without lighting the gas.

The immediate ignitions require high temperatures of the filament for their production. For lower temperatures the filament burns without lighting the gas, or produces retarded ignitions.

When breaking the bulbs in the testing apparatus itself, we obtain immediate ignitions with lamps working at their normal voltage. The same temperature of the filament may evidently be produced by a weaker current when the filament is in vacuum than when it is in the air.

The minimum temperature necessary to obtain these ignitions is about 2050 deg. C. The majority of the four-volt lamps tested work normally at temperatures above this latter; those whose filaments have a lower temperature, have a weak lighting power, and their consumption of energy per unit of luminous effect is excessive.

It has often happened that when the bulbs were broken in the testing apparatus itself, retarded ignitions were obtained for temperatures very much above 2050 deg., but there is room for believing that the manner in which the bulb was broken influenced these results. As has been explained above, it seems reasonable that the temperature of the wire decreased before the ignition was able to pass to the outside through the cracks between the fragments of the broken bulb. To avoid too frequent breakages of the filament by fall of the pieces of glass when the bulb broke, we coated the jaws of the vise with a cement, so as to hold the fragments. This explains the ease with which they could be held in contact.

Influence of Resistance in the Circuit

The retarded ignitions seem due, in part at least, to the influence of the electrical resistance of the circuit on which the bulbs were connected.

This resistance is composed of:

1. The interior resistance of the battery of storage cells.
2. The resistance of the conductors.
3. The resistance interposed, in the majority of tests, to regulate the difference of potential at the contacts of the lamp.

The electromotive force absorbed in these resistances decreases when the intensity of the current lessens, and this falling off of intensity occurs in the course of the tests when the combustion of the filament reduces its diameter and increases its resistance. During the tests, the difference of potential at the binding posts of the filament therefore increases proportionally as the electromotive force absorbed in the external resistance diminishes, and from this may result an elevation of the temperature of the reduced wire. By observing with a pyrometer the combustion of a filament put in circuit with a resistance, we note that its temperature consistently increases, which is not observed when the tension at the binding posts of the lamp is constant.

It seems, therefore, that the resistance of the exterior circuit of the lamp must be, at least in part, the cause of the retarded ignitions. The temperature of the filament, which is too low at the beginning of the test to ignite the explosive mixture, gradually increases up to the point of ignition and may then cause immediate or less retarded ignitions.

When the filament has been much reduced by a series of successive incandescences, the difference of potential at the binding posts of the lamp differs little from the electromotive force of the battery. The filament then behaves as if the difference of potential at the binding posts of the lamp were constant; its temperature decreases at each incandescence and finally it burns up without lighting the gas.

The experiments made on lamps opened before introduction into the testing apparatus, show that in order to light the firedamp when the speed of the gaseous current is increased it is necessary to increase the superpressure on the lamps. This result, due to the greater cooling undergone by the filament in high-speed currents, could have been predicted in advance.

Experiments with Metallic-filament Lamps

We know that the illuminating power and the efficiency of incandescent lamps rapidly increase with the temperature to which the filament is carried. Taking as a unit the brilliancy of platinum at its fusing temperature, M. Violle found the following relations between the luminous intensities at the various temperatures:

Temperatures	Relative Intensities
775 deg.	0.00007
956 deg.	0.00120
1035 deg.	0.00450
1500 deg.	0.27100
1775 deg.	1.00000

For temperatures above that which corresponds to a consumption of 3.5 watts per candlepower, the carbon-filament lamps are quickly burned out. To improve the efficiency of the lamps, it is necessary to resort to certain refractory metals, such as tungsten, tantalum, iridium, osmium, zirconium, etc., filaments of which can stand higher temperatures without too rapid injury.

Osmium melts only at about 2500 deg., tantalum between 2250 and 2300, iridium at 1900, according to Violle, and between 2200 and 2300 according to Weyle. The temperature of fusion of tungsten is about 3080 deg., according to Burgess and Waidner, and of tantalum, 2910 degrees.

The metallic-filament lamps normally run at very high temperatures. According to the U. S. Bureau of Standards, the working temperature for tantalum lamps is 2000 deg., and that of tungsten lamps 2300 degrees.

By reason of the high temperature of their filaments, it might have been predicted from the start that these lamps would be more dangerous as regards ignition of gas than carbon-filament lamps. All the metallic-filament lamps experimented with have lighted the gas at their normal working temperature, and even at lower temperatures.

In a certain number of cases, several consecutive ignitions were obtained with the same filament, which shows that it is indeed the incandescence, and not only the spark of rupture, which causes the explosion. One filament, notably, gave 14 consecutive ignitions before breaking. In the cases where only one ignition was obtained, it was often noted that a current continued to circulate in the filament after the explosion of the gas, which shows that it was not interrupted. Certain metallic filaments have lighted firedamp at temperatures which with carbon-filament lamps present no danger.

Conclusions

It follows from these tests taken all together that the rupture of the bulb of an electric mine lamp with carbon or metallic filament must be regarded as dangerous in a gaseous atmosphere.

It is possible to manufacture lamps whose filaments will not reach a dangerous temperature, but the lighting power of these lamps will probably be very feeble, and the consumption of power per unit of light excessive.

By reason of the importance of this question of good underground lighting, it is preferable not to follow this method, but rather to seek to obtain electric mine lamps of high lighting power by raising the temperature of the filament up to the limit consistent with the required degree of durability. Under these conditions magnificent lighting powers may be obtained, but in order to get them it is necessary that the storage battery shall deliver during a working shift a current of 1.5 amp. at two volts, or better a current of 1 amp. at four volts.

And it is then absolutely necessary to guard against the danger resulting from a breakage of the bulb, by surrounding this with a thick and strong glass envelop with hermetically sealed joints.

Permanent Roof Sustention

By R. Dawson Hall

The blasting of rock causes it to occupy increased space. This property is utilized to provide support for the roof, chamber filling for miners to work on, and dams for culm flushing.

William Griffith, one of the distinguished engineers appointed by the Scranton Mine Cave Commission to investigate on its behalf the inadequate support of the city by the pillars of the coal mines thereunder, has filed two patents, Nos. 1,004,418 and 1,004,419. The first of these covers, among other matters, one of the recommendations embodied in his report to the city. That report advocated the method of filling up the workings by the blasting of the roof and floor. The greater volume occupied by the blasted rock is relied on to fill the place vacated by both rock and coal, and to support the roof.

Mine Cave Commission

To quote the words of Messrs. Griffith and Conner in their report: "It is a well known fact that loose rock occupies from 1⅔ to twice the volume of the same weight of rock in place. In other words, if a cubic yard of bed rock be broken to pieces, it will occupy a space of 1⅔ to 2 cu.yd. Your engineers have conceived the idea of taking advantage of this fact, well known to engineers, for the purpose of cheaply producing an adequate support of the rock and surface above certain classes of coal beds under the city of Scranton. So far as we know, this method, in its entirety, has never been used before in any coal-mining district, and the suggestion is here made for the first time.

"The process is applicable to beds less than 6 ft. in thickness, and so located that the shock in heavy blasting will not produce ruptures of the measures supporting adjacent coalbeds. It consists simply in blowing up the floor and shooting down the roof of the mine, each to a depth equal to the thickness of the coal bed. This produces a total thickness of loose rock equal to three times the thickness of the coal. The rock would be well packed together and have great supporting power, and moreover the desired ends would be attained in a comparatively inexpensive manner.

"This method might be adopted throughout the Dunmore seams, by blasting down the roof and lifting the floor in the abandoned rooms or in the roadways between the gob piles in the chambers. Wherever it is applied efforts should be made to fill completely the whole width of the chamber or roadway from wall to wall, so that the loose rock may be confined between the pillars, thus greatly increasing the resistance to compression."

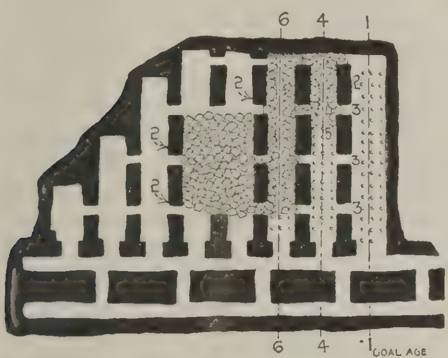

Fig. 1. Room-and-pillar Filling

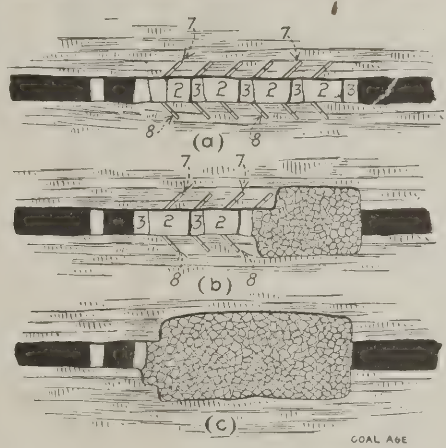

Fig. 2. Vertical Sections of Fig. 1.

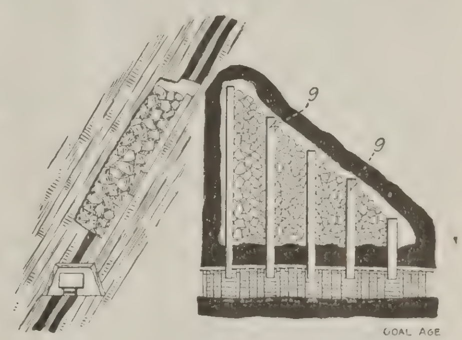

Fig. 3. Filled Longwall Working

Strength of Broken Rock

The following table taken from the same report gives a marked illustration of the value of rock fills for roof support. The measure of strength on which it is based is the number of feet of coal-measure rock necessary to compress the roof supports described, to the percentage of their height given at the head of the columns.

Thus a loose pile of broken sandstone of such size that all the material of which it is composed will pass through a 1¾-in. ring, and containing voids aggregating 40 per cent. of the whole mass and moreover without aid from lateral confinement, will shrink 5 per cent. when loaded with 20 ft. of rock, and 30 per cent. when loaded with 298 ft. of the same.

Rock Blasting in Level Measures

The method of operating under this plan is illustrated in five cuts. Fig. 1 shows a plan of a regular room-and-pillar working where the pitch of the measures is gentle. The room on the right is typical of the average anthracite workings. Fig. 2 (*a*) shows a vertical section along 1-1. In both plan and section, 2 represents the pillars between the crosscuts 3. Fig. 2 (*b*) shows a vertical section along 4-4. From 5 to the end of the room, the proposed method of roof support has been adopted and the whole space has been filled with the débris. In Fig. 2 (*c*) is seen a vertical section 6-6 of the third chamber, the shooting of the top and bottom having reached a further stage. The holes marked 7 in the roof and 8 in the floor are bore holes prepared for the blowing of the roof and of

the floor. The proposals of the inventor are to use this method for different purposes, either on "first" mining to permit complete extraction at one operation or after first mining to provide for the robbing of pillars left in. It is also claimed that the roof will be upheld by the broken rock at all times, so that the surface will have a minimum subsidence. The intention is to use the rock where it is blasted. Mr. Griffith prefers to blow the holes in roof and floor alternately, apparently with the idea of breaking the rock more completely and in order that the rock in falling may fall on an uneven surface and roll over in a manner conducive to the creation of large interstitial spaces. The bore holes being inclined at 45 degrees to the strata, the roof rock will be shattered so that the same purpose of volumetric increase will be assured by that means also.

Mr. Griffith proposes either to fill the workings with broken rock while advancing in long wall or to fill alternate rooms in room-and-pillar workings and to extract from the unfilled rooms the pillars on either side of the same. These unsupported rooms and extracted pillar spaces can be subjected on the retreat to like treatment, the floor and top being blasted as the pillars are removed.

The inventor points out that the method is adapted to old workings as an assistance to pillars left in first mining or as a means of withdrawing those pillars.

Rock Blasting for Support of Miners at Face

Fig. 3 also illustrates the first patent, but contemplates a somewhat different method of mining. The right half of the figure shows the plan of a longwall advancing method in steep measures intended to be pursued only for one panel at a time. From a gangway, a number of openings are driven up the pitch till a sufficient pillar is left to protect the heading. Then the openings are widened out, as is shown, so that no pillars remain between the various openings. To keep the passageway open for the miners and the coal, a chute is built of timber, metal or other desirable material. The miners can enter by any of these chutes. The coal is shown as having a slate split between upper and lower benches. This layer can be taken out and thrown back. If it proves unequal to filling the space behind, the roof is to be blown down, filling the whole area in such manner that complete sustention is assured. On this platform of rock the miner can work without difficulty.

Blasting with Flushing

The second patent No. 1,004,419 contemplates a change in the old-time culm or sand-flushing methods. In Fig. 4 (*a*) are shown three rooms from which the pillars and heading stump pillars are removed. Within the space thus left unsupported, the roof and floor are shot in a roughly circular ring, the shooting being regulated so that the blasted rock will make a complete circular wall, filling not only the place where the coal was excavated, but the space from which the rock itself was blasted. This blasted rock is expected to fall in such manner that it will key itself firmly and resist extrusion. A section 2-2 taken through the chamber is shown in Fig. 4 (*b*). It will be seen how the rock 1 fills the blasted

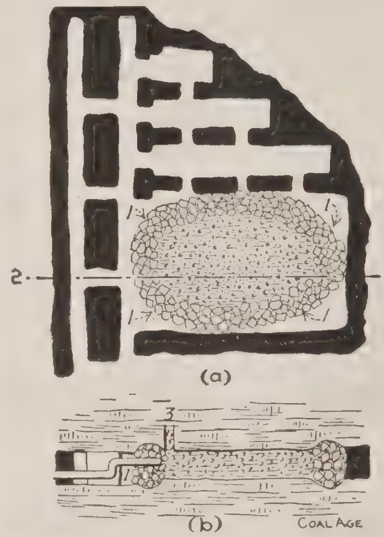

Fig. 4. Continuous Rock Dam for Flushing

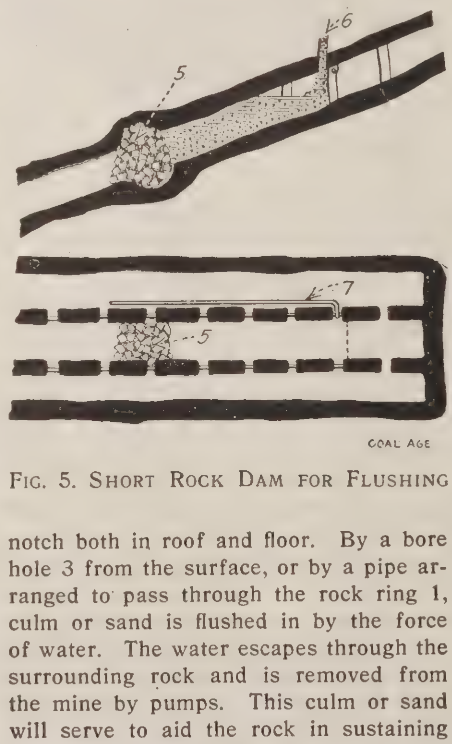

Fig. 5. Short Rock Dam for Flushing

notch both in roof and floor. By a bore hole 3 from the surface, or by a pipe arranged to pass through the rock ring 1, culm or sand is flushed in by the force of water. The water escapes through the surrounding rock and is removed from the mine by pumps. This culm or sand will serve to aid the rock in sustaining the roof. It will then be possible to rely on this artificial pillar and to remove adjacent pillars. The coal pillars thus removed can be replaced by the erection of another artificial pillar like that just described. Fig. 5 is a plan of a heavily pitching chamber with the usual crosscuts on either side. Mr. Griffith proposes to blast a dam 5 by shots in the roof and floor and then by means of a bore hole 6 leading to the surface, or by a pipe 7 passing through a brattice, to flush culm or sand or other material till the chamber is filled, the lateral movement of the filling being resisted by the brattices, as in the case of the foregoing patent. The artificial pillars thus created can be used for maintaining the roof in abandoned workings or during second mining, where merely the sustention of the surface is sought or it may be used in first mining to aid in a final recovery of the coal.

The systems by Mr. Griffith appear a notable addition to the present practice of mining. The need for an increase in the practice of "flushing" or "slushing" or for a system replacing it is keenly felt. The time is passing when it can be confidently asserted that the value of the pillars is less than the cost of their recovery by approved methods.

Italy's Coal Trade

Italy mines annually about 500,000 metric tons of lignite and imports each year 10,000,000 metric tons of various kinds of coal, according to Vice-Consul Alden March, who writes from Leghorn in the province of Tuscany. The United Kingdom practically controls these imports. Cheap freight rates and the opportunity to take home return cargoes count heavily in favor of the British mine operators.

The industrial development of Italy will demand annually greater quantities of coal. In many localities the wood supply for domestic purposes is growing smaller, and the more general introduction of coal stoves makes for a larger consumption of anthracite. These conditions would seem to warrant the serious consideration of American coal men.

In the Leghorn district there is an increasing demand for all kinds of coal. It is used for railways, manufactories, smelters, and to supply household demands. The province of Tuscany, of which Leghorn is the port of entry, consumes annually about 100,000 tons of domestic lignite, 300,000 tons of Cardiff steam coal, 100,000 tons of North Country and Scotch coal, 120,000 tons of Newcastle gas coal, and 50,000 tons of Westphalian coal, to which may be added about 10,000 tons of so called patent fuel. No coal is at present imported from the United States.

Sometimes a good way to promote the market for a given kind of coal is to conduct a campaign of education on the proper way to use it.

Coal Situation in Germany, 1911

By O. H. Hahn*

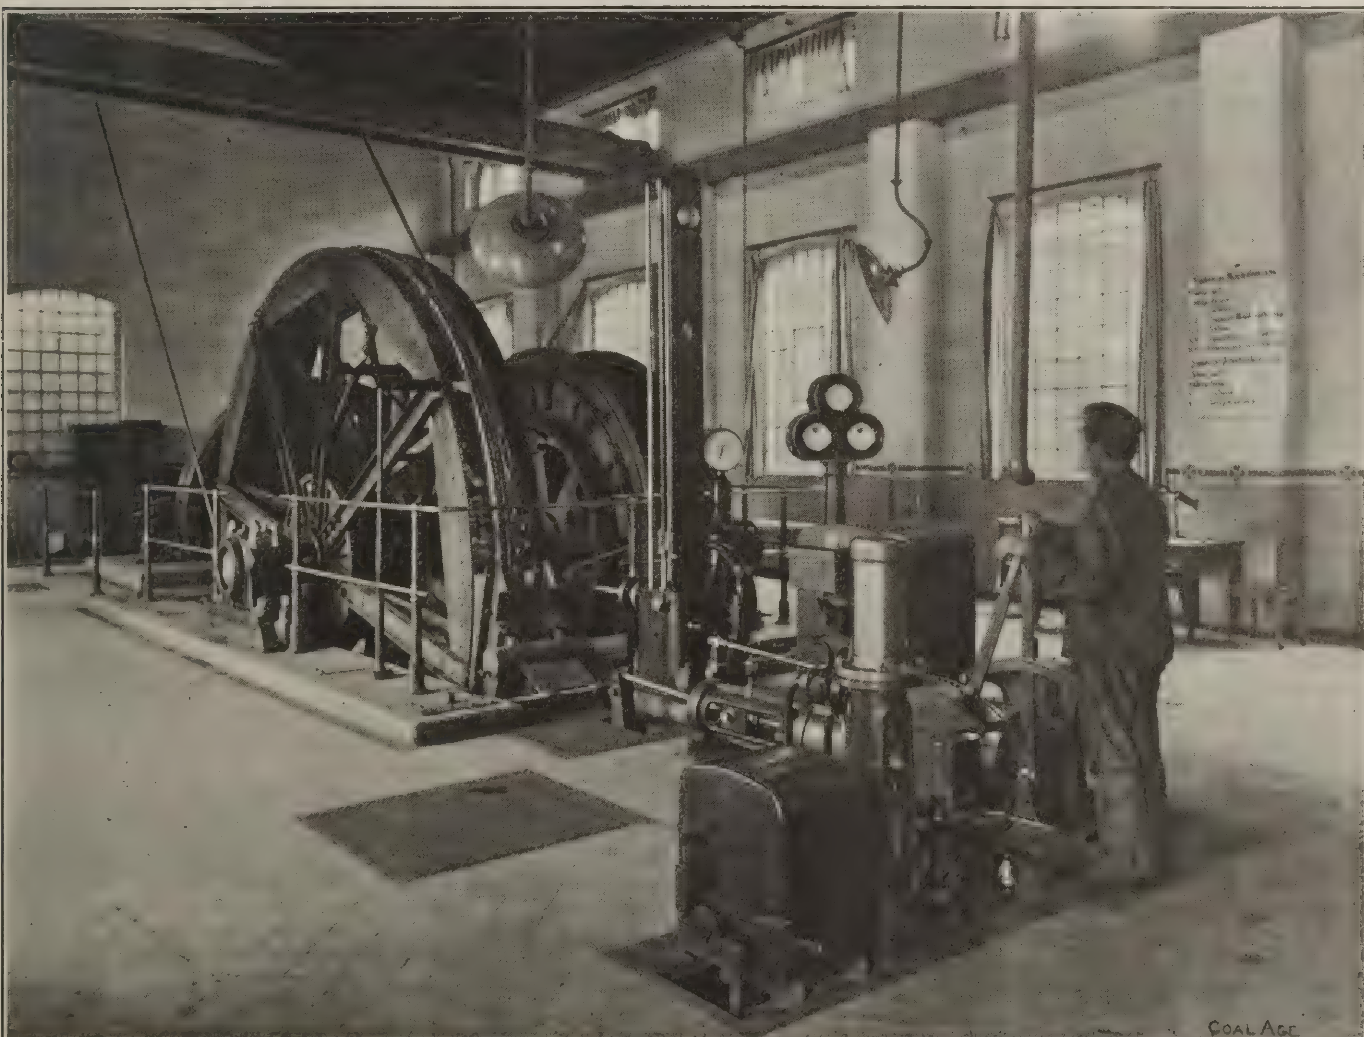
The state railroads furnished an inadequate car supply while drouth in rivers made demand for rail transportation heavy. Silesian coal is being replaced in foreign markets by British. Government admits its error in purchase of Stockheim colliery. Sixty-five million tons of lignite mined.

*Schillerstrasse 6, Jena, Germany.

During the year just past, the regular production and disposal of coal has been greatly hampered, owing to the inadequate supply of rolling stock furnished by the state railways for the transportation of the product of the collieries and iron works. The situation was aggravated still more by the uncommon drouth which put a stop to navigation on rivers and canals for a period of two and, in some cases, three months, whereby additional freight was thrown on the hands of the railroads. The newspapers of the industrial districts published daily lists of cars ordered and furnished, which must have been unpleasant reading to the government officials. Thus, for instance, in Upper Silesia during 14 days in October, out of 43,108 cars demanded per working day, there was a shortage of 3079 cars. At Essen, Rhenish Prussia, of 29,201 cars ordered there was a shortage of 6145, and so forth. The effects of such a state of affairs are manifold and distressing. The surplus output of mines, briquet factories, etc., has to be stored in the yard or outside, which causes extra expense and injury to the quality of the material by weathering. When the limit of space is reached, the output has to be curtailed, and this only can be done by putting the workmen on half time or by laying them off altogether. This means diminished earnings for them, and this is especially hard at the present time, when all commodities of life have gone up in price. Discontent of the workmen will lead to strikes, and signs of unrest have been apparent for some time in the Ruhr district, one of the busiest in the country. As general expense, maintenance of plant, etc., will remain the same, the cost of the products will, of course, become higher. Consumers will also suffer by not being able to rely on their orders being filled. Nevertheless, in the face of these adverse circumstances, the production of coal in 1911 has kept up to the figure of 1910, viz., 150 million tons.

Independent Coke Producers Suffer

Coke is rather a drug in the market at all so called "reine Zechen," which are collieries not connected with iron works. The "Hüttenzechen," or furnace-owned collieries, are competing with the "reine Zechen" in the disposal of their surplus coke. Through lack of shipping facilities the "reine Zechen" have not been able to ship much of their coke abroad. It is true there is a pool, the Rhenish-Westphalian coal syndicate, composed of



Interior of Hoist House, Showing Main-pit Winding Machine at a German Colliery

"Hüttenzechen" to regulate and maintain prices, but the "reine Zechen" would fare badly in joining that organization, as their quota of production would be set as low as possible by the pool.

So it is fortunate that some of the byproducts made by the coke-producing collieries find a ready market. Thus, there is an ever-growing demand for sulphate of ammonia, while tar, benzol, naphthalene, solvent naphtha, toluol, etc., also sell briskly at times. Moreover, gas is often sold for power. The byproducts of the Rhenish-Westphalian district are disposed of by a joint selling agency at Bochum, which is called the "Deutsche Ammoniak-Verkaufsvereinigung." The prices are made up on the basis of the London quotations.

Silesian industry, especially the Upper Silesian collieries, are clamoring more than ever, and with good reason, for a reduction of railroad rates to reconquer the Berlin market for coal, which they have lost to Great Britain.

Misplaced Investments

The kingdom of Bavaria, which is not rich in mineral treasures, especially not in coal, has suffered a serious financial loss in the collapse of its Stockheim colliery. It was purchased by the state from private parties only 2 or 3 years ago for 2½ million marks ($595,000) on the representation that it had a reserve of 5 million tons of good coking coal. After putting up a costly coal-cleaning works and on opening up the mine on a large scale, it was found that the coal was almost worthless. To cut off the recurrent losses the mine was finally shut down, and the government had to make a clean breast of its mistake to the Diet; not a pleasant duty by any means. Besides it had to find employment for the people depending on the mine work for their living.

In Westphalia, the "Stolberger Aktien Gesellschaft" was obliged to close its Lukas colliery, after having spent several years of labor and several million marks in money on opening it. The reasons for so doing have not been made public.

Lignite Tonnage is Large

Germany has an abundant supply of lignite in its tertiary formation. There are 18 distinct districts, foremost of which in production is the Thuringian-Saxonian, with an output of 25 million tons. Then follow the Lower Rhenish and the Lower Lusatian with an equal output of 15 million tons. All told, 481 mines yield about 65 million tons. A large portion of the lignite is briquetted, for in this shape it is better suited to household use. In industrial establishments, where the mine-run coal is used, step-grates are required for burning it. The lignite mines are frequently owned by or connected with beet-sugar factories, cement factories, brick-yards, etc. One of the largest lignite mines is the "Marga," owned by the Ilse Brown Coal M. Co., in Upper Lusatia. It is equipped with 36 briquet presses and the largest steam shovel in Europe, if not anywhere. The sale of briquets is also controlled by selling agencies, in order to prevent demoralization of the markets. The lignite producers have to compete with their Bohemian colleagues to a certain extent, as the latter have cheaper labor and river navigation in their favor. The new law passed by the Reichstag, which authorizes the levying of river toll by the government, may destroy this competition.

Electric Transmission in Coal Mines

By Henry D. Jackson *

The transmission system is frequently a neglected part of the electrical equipment in coal mines. Its proper installation and maintenance are, however, most important factors in reducing the cost of power and securing the operation of electrical apparatus against undue expense for repairs.

Within the past few years the use of electricity in coal mining has increased rapidly, particularly the introduction of alternating-current generating and distributing systems. These usually deliver high-voltage alternating current to substations where it is transformed to direct current for use in and about the mines.

Direct-current generation and distribution have been in use for some time, and have proved in many respects far more satisfactory than compressed air and other forms of power. In many cases they have operated to displace both mules and compressed air as means for hauling coal cars over long distances, although mules are still in general use for bringing the cars from the rooms to the entries or to the electric-haulage system. In gaseous mines, mules and compressed air are still largely employed, but even in this field the gradual displacement of both seems probable as a result of the development of the storage-battery locomotive, which has all its parts carefully inclosed, the controllers operating under oil.

It is a curious fact that in many mines operating by means of direct current, the distribution system is frequently neglected to a far greater extent than is warranted by the conditions. As a rule the stations are fairly well kept up and operated with average economy. The locomotives are kept in fair condition considering the work they have to do and the labor that is employed to operate them; but the transmission system, by which is meant the wires or cables carrying current to the motors and the track or return circuit carrying current back to the station, is often kept in bad shape. So far as I have been able to ascertain, the reason for this is the illogical assumption that, owing to the fact that coal costs the mining operator but little, the power cost is proportionately low. The coal should be charged up to the power plant at a price equivalent to that for which it might be sold, unless it happens, as it does in some cases, that the coal used is the culm pile, under which conditions it would naturally be considered as having no value beyond the cost of taking it from the mine and delivering it to the bunkers.

True Cost of Electric Power

Under most conditions, coal operators seem to consider that the cost of electricity as delivered to the machines or to the line, is the plant operating cost only, that is to say, the cost of the labor, oil, water, coal, and possibly the maintenance charges. This, however, is not true. The cost of power should take into account the interest, depreciation, etc., on the power plant, and in many cases an allowance for pretty heavy taxes. The cost of power plants in the coal regions is not low, owing, among other reasons, to the fact that in many cases the plants are so located as to involve a considerable charge for the delivery and erection of machinery, so that the interest charges are heavy, the repair charges equally heavy, and the total cost of power is greatly in excess of the operating charges alone.

Economical use of the power generated is therefore necessary to reduce to a minimum the size of the units which may be required for such power generation, or, in other words, to secure the operation of the largest possible number of locomotives and other apparatus with the minimum power output. This can be done only by keeping the transmission system always working at an efficient point; by doing away with excessive transmission losses

*Associated with T. W. Sprague and F. H. Keyes, as consulting engineers, 88 Broad St., Boston, Mass.

due to the use of small feeders, leakage losses due to poor installation and losses in the return circuit through poor bonding and restricted area of the return feeders.

Besides the waste of power, another feature of excessive losses on the transmission line, which is equally bad from the operating standpoint, is the consequent increased heating of the motors and the reduction in the speed or power of the locomotives which results in a marked decrease in their hauling capacity or in the amount of coal that can be handled by a stated number of locomotives. It is a fact that for the best results as regards economy of distribution, the interest and maintenance cost of the copper and the return circuit should be equal to the cost of power lost over them during the year. If the lost-power cost is greater than the interest and maintenance, the circuit is too small; if it is less, the copper is too large. This is true, however, solely from the financial and theoretical standpoints. There are other considerations than these. In a small plant, it is impossible to put in a small enough amount of copper to fulfill the above condition, because such an amount would not allow the operation of the locomotives at all; and in a large plant, the amount of copper called for would be far too small. So, this condition is a point to be taken into account but should be supplemented by considerations which are necessary to insure that the motors will get sufficient power for their operation and will be enabled to work at their full capacity without excessive heating and repairs.

Calculation of Copper Required

In installing the copper for a transmission system, it is advisable to make some calculation as to the probable load that will be brought upon the system, and locate the approximate center of the load. Then, on the principle that the voltage at this center of distribution should not drop below a point at which the motors will operate satisfactorily with the maximum current on the line, the total resistance of the line should be determined from the formula

$$R = \frac{E}{C}$$

where

R represents the resistance;

C represents the current;

E represents the electromotive force.

Then E will represent the electromotive force lost over the wires or the total drop in the circuit. Knowing the dimensions of the rails, the resistance of these can readily be calculated by figuring that each pound of rail per yard is equal to 9000 circular mills of copper. Then, knowing the length of the rails, their total resistance can be figured, and the difference between this amount and the value of R as calculated by the above formula, will represent the resistance which may be allowed for the overhead conductor. If it turns out that it is more expensive to install copper overhead than it is to add it to the return circuit, additional copper may be used for the return, and a smaller amount used overhead. After this copper has been figured, and laid out, it can, of course, be distributed so that it covers the entire line to be electrified, using a heavy section up to a point at about the center of the load and from there on, reducing its size at intervals, in accordance with the length of the line, until finally the trolley wire alone is carried to the extreme end.

Having laid out the copper in this way, a load curve should be approximated, showing as nearly as can be the actual amount of power used from time to time throughout the day, and, if possible, the average for the year. As a matter of fact, the average is not the best figure to use, because the power lost over the wires is equal to the current squared, times the resistance, and the discrepancy will be considerable between the calculated and actual drop in voltage during a period of overload, but for all practical purposes, if the average is multiplied by $1\frac{1}{10}$, this figure will give near enough to the figure required for determining the loss. By multiplying the total resistance of the circuit by the square of $1\frac{1}{10}$ times the average current and by the total number of hours in which it is used during the year, the power lost for the year may be calculated. If by adding additional copper this loss can be reduced to such a figure that the cost of the wasted power will more than pay for the interest on the additional copper required, this copper should be installed as an evident economy.

Rail Bonding

On the return circuit, rail bonds are necessarily used in order to secure a good electrical circuit. These bonds are a continual source of trouble, frequently giving out and resulting in a high resistance on the return circuit. They should always be kept in good condition. It costs but little to keep them so, and the loss due to a single bond when in bad shape is equal in a year to many times the cost of the bond itself; moreover, the operation of the haulage road is otherwise materially affected. A good transmission system, properly designed and worked out so that its losses are kept low, will result in:

1. A decided reduction in the amount of power required to be generated.
2. A low cost of power distribution.
3. A considerable increase in the amount of coal that can be handled.
4. A marked reduction in the motor repairs, both for the locomotives and the cutting machinery, because of the smaller current required for their operation, owing to the higher voltage.

These are points well worth considering, and the transmission system is an item worthy of far greater attention than it now receives.

Electrically Operated West Virginia Mines

By F. C. Perkins*

Electric locomotives as well as electrically driven pumps and ventilators are used extensively at the mines of the Davis Coal and Coke Company in West Virginia. This company owns 160,000 acres of coal land and operates mines, along the lines of the Western Maryland Railroad, at West Virginia Central junction, Elk Garden, Harrison Henry, Coketon, Weaver and Thomas.

At Thomas, W. Va., the Upper Freeport coal is mined by drifts at tipple height above the railroad. Mine No. 23 has been operated for a number of years and has extensive workings but is still a good mine, producing 1200 tons of coal per day from a seam 8½ ft. thick and free from noxious gases. Mine No. 25 is directly opposite with a drift opening slightly to the dip in the same seam of coal, and mine No. 24 is worked by a shaft 20 ft. deep penetrating to the Davis seam of the Lower Kittanning. This group of mines is operated entirely by electric haulage and other electrically driven equipment.

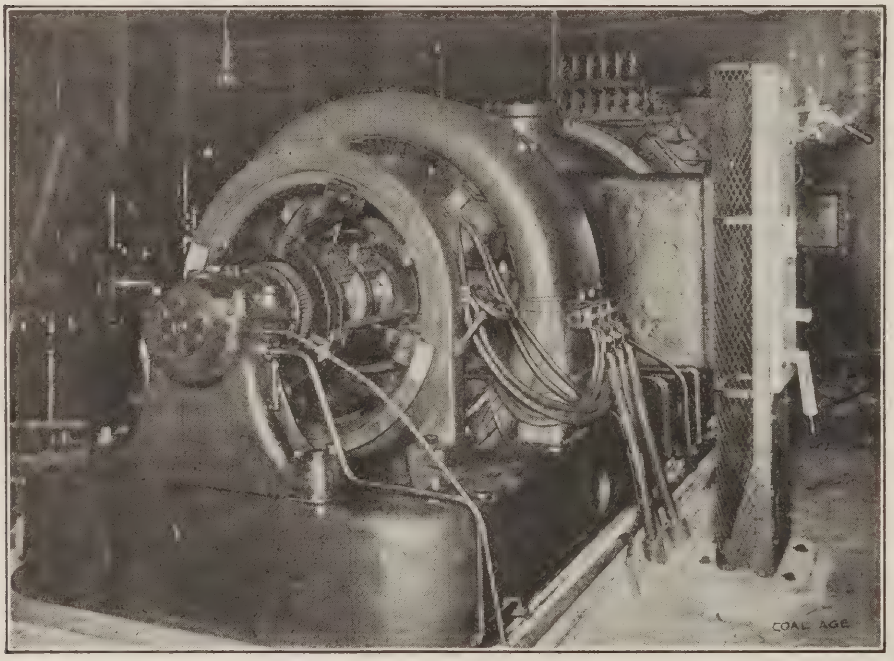
There are also 114 coke ovens at this plant served by electrically operated coke larries of the General Electric type. The results obtained with these larries, which run along the top of the ovens where the heat is at times excessive, and where the fumes would be injurious to horses or mules, have been excellent. It has been found also that they are much quicker in operation than the animal-propelled variety because the control is so perfect that when about to discharge into the oven they can be moved backward or forward an inch at a time. They are used either independently or with trailers, and offer a flexibility not otherwise obtainable.

While the operation of the electrically equipped larries has always been all that could be desired, more or less trouble was experienced from time to time with the haulage locomotives, as the workings in these mines became more and more extensive, the length of hauls greater, and some steep grades necessary. To remedy this condition the capacity of the trolley lines and feeders was increased by the addition of copper in order to reduce the drop in voltage which took place when heavy loads were started up at the working face, the track bonding was thoroughly overhauled, and the rails put in condition.

*Buffalo, New York.

The Turbo-generator

However, it was only upon the installation of the 500-kw., 600-volt, direct-current steam turbo-generator shown in the illustration, that these troubles entirely disappeared. The turbine is of the Curtis horizontal, high pressure type, operates at a speed of 1800 r.p.m. and is directly coupled to a four-pole General Electric dynamo. It is considered to have demonstrated the particular suitability of this type of prime mover for handling the enormous fluctuations in load which occur in mining work. The normal current of this machine at full load is 833 amp. but the unit is continually called upon to handle loads varying from practically 0 to 1450 amp. and these variations recur, sometimes at intervals of a minute or less; for example when a train is picking up cars at the far end of the mine. This installation possesses the steadiness required to stand up under these severe conditions and there has resulted the entire disappearance of the formally frequent burn-outs of motor armatures, etc.



Direct-current Turbo-generator Set, Thomas Mines

The 500 kw. turbine generator provides current for one 20-ton and eight 13-ton electric locomotives and for the coke-oven larries.

Direct-current series motors were adopted at this mine for haulage and hoisting purposes because of their characteristically high torque at starting, and it was decided to generate power at a potential of 600 volts owing to the long distances to which it had to be transmitted. It is maintained that the objection of increased danger to men and animals, where the latter are still used for gathering purposes, which might be raised against this high potential is more imaginary than real because of the fact that the current is turned off while the shifts are changing and, as a matter of fact, there has been no loss of human life from electric shocks in the company's entire history.

While 600-volt direct current is used for haulage in all of the various workings, three-phase alternating current is employed for practically all other purposes around the mine. For street lighting, single-phase alternating current, derived from constant-current tub transformers, is used. The power plant is equipped with two 100-kw. three-phase 60-cycle alternators, for operating the tipple machinery and the pumps. There are three of the latter in use, one having a 3-in. suction and 2½-in. discharge, one a 6-in. suction and 5-in. discharge and one a 10-in. suction and 8-in. discharge.

Automatic Water Purifying System

The purification of water for boiler feed and other industrial purposes is quite essential in many plants. Numerous machines and devices for this purpose are on the market and the selection of one for any particular case depends largely on the cost of installing and operating the same.

An apparatus for water purifying, which is entirely automatic in its operation and one which may be installed for a comparatively moderate price has recently been put on the market by the Geo. W. Lord Co., of Philadelphia, Penn. The apparatus consists principally of one large settling and filtering tank, two mixing tanks, one chemical storage tank, and two measuring chambers.

The incoming water first passes over a waterwheel which furnishes the power to operate paddles in the mixing tanks and chemical storage tank. From the wheel, the water flows to either one or the other of the two mixing tanks directly below, where it comes in contact with the chemicals flowing in by gravity from the chemical storage tank. The solution of chemicals is measured out by an automatic measuring valve, and the speed of operation of this valve varies with the flow of the water. Hence, the correct amount of chemicals is mixed with the water, no matter what the rate of flow may be.

From the mixing tanks, the water flows through a large cylindrical tube, to the bottom of the settling and filter tank where it drops the bulk of the precipitates which are formed, into the cone-shaped hopper bottom of the tank, whence they are removed through a sludge valve designed for this purpose. The water then rises, and after passing through an excelsior filter flows off through the outlet pipe at the top of the tank.

The inlet and outlet pipes of the two mixing tanks are controlled by lever valves, which are automatically operated so as to cause the water to flow first into one and then into the other of the tanks. These valves, as well as the chemical measuring valve, are operated by sets of levers which are shifted by a dumping bucket, the latter being actuated by the weight of water run in from overflow pipes.

A valve in the inlet pipe, which is governed by a float in the filtering tank, controls the entire operation of the apparatus.

Rules for Firing Shots

The following drilling and shot-firing regulations make for efficiency and safety as well as economy of time, labor and powder:

(1) Holes drilled in solid faces should be 6 ft. apart horizontally.

(2) Extract all coal dust from the drill holes before charging.

(3) Undercutting should extend at least 6 in. beyond the drill hole.

(4) Drill holes should be at the least 2 ft. 6 in. deep.

(5) The bottom of holes drilled in a solid corner should come within 1 ft. of the rib line.

(6) Giant powder should never be issued to miners while it is frozen, and should always be carried in canvas bags.

Boyles law states that, "the volume of a gas is inversely proportional to the pressure upon it, providing the temperature remains the same," hence variations in atmospheric pressure have a marked effect upon the quantity of gas given off by a coal seam. When a reduction in pressure takes place the amount of gas given off increases and gob gas overflows.

COAL AGE

Investigation of Explosives

Recent discussions by English engineers show that there is the same diversity of opinion on coal-mining problems in Europe as exists in America.

At a December meeting of British mining men, J. J. Prest in speaking of methods for laying coal dust said: "The one fact that stands out to my mind in all these experiments, is that a sufficiently large sum of money has not been placed at the disposal of the experimental committee of the government, to ascertain whether it is not possible to obtain an explosive that will not ignite coal dust.

"We seem to have gone on the other tack of spending thousands of dollars in demonstrating the inflammability and danger of coal dust. Experiments have been repeated, *ad nauseum*, to demonstrate only that coal dust is dangerous, whereas, if a tithe of the money had been spent in the direction of endeavoring to produce an explosive that will not inflame, or cause an explosion where coal dust is present in large quantities, then some of the money would have been usefully spent. I do not think it humanly possible to remove coal dust from the workings of a mine, and all the experiments and suggestions which have been made are simply playing with the subject."

While we do not agree entirely with the views of Mr. Prest, because the money recently expended in this country by the Bureau of Mines on investigations of explosives, has resulted in much good; it is a fact that the greatest basic danger to coal mines would be remedied if explosives could be made absolutely safe.

There has been a considerable advance in the manufacture of mine explosives during the past two years, but the best powders we have today still flame, and when conditions are right, an ignition of gas or dust is liable to occur.

We believe with Mr. Prest that a greater proportion of the money now being spent on investigations leading to safety in coal mining, should be diverted to a serious solution of the explosives problem. The present terms, "permitted," "safety," "flameless," etc., only mean that one powder is a little less dangerous than another brand.

Some More Electrical Don'ts

The following "don'ts" are submitted for addition to the electrical warning list, recently issued by the Bureau of Mines.

(1) Don't permit the use of timber near your underground electrical pumps and other stationary motors. A fire took place, July 17, 1910, at the Devon colliery of the Alloa Coal Company, Clackmannan, Scotland, in a pump room containing a 70-hp. motor driving a triplex pump. This fire could not have been started by lamps for none were present. It evidently originated at the motor controller because that was the only part seriously burned. The controller was filled with oil which is believed to have ignited, setting fire to the timber and thus filling the mine with a dense cloud of smoke.

How this fire occurred is open to doubt. Either a fuse, in blowing out, ignited the fumes from the 10 or 12 gal. of oil which the resistance and switchbox contained, or else the oil was ignited by a short circuit between the terminals just inside the box. Two men were killed by passing through the smoke. Two other fires occurred: one on Aug. 17, 1910, at Pleasley colliery, Derbyshire, and the other on Oct. 1 at the Manvers Main colliery, Yorkshire. Both these fires were caused by the fusing of a cable at or near the entrance of a pump room, the resulting arc setting fire to the adjacent timber. In 1909 at the Blaenant colliery in South Wales a similar accident occurred with fatal results, and a number of fires have been caused by the same agency.

(2) Don't put a trolley wire or other bare conductor where it may, on falling, cross another bare wire which is not usually charged or is generally charged at a lower potential.

An insulator on an overhead electric line broke and permitted the wire to come in contact with a steel stay. Some cars left the track and made a contact with the

latter. A yard foreman who assisted the driver of the trip received a fatal shock. It is needless to point out how essential it is to protect electric wires from non-electric or from other electric wires of a different potential. Signal wires and shot-firing wires should be kept away from trolley wires.

(3) Don't put a bare wire such as a stack or other stay wire, where on failing it will cross-circuit a trolley wire or bare conductor. This is dangerous because, if the wire breaks as it probably will, between the ground and the trolley wire, there will be no direct grounding, and the return may cause a fire, and electrify a conducting body which normally is harmless.

(4) Don't leave unsafe trees near trolley lines. A motorman in the southern part of West Virginia received a severe shock from a fallen trolley line, the line being brought down by the fall of a rotten tree in a heavy gale.

(5) Don't install your fuses near an oil controller box, for if a fuse burns out ignition of the fumes from the oil may result.

(6) Don't install oil controller boxes when using a low-potential current in mines where naked lights are permitted. In such a case they are a menace without compensating advantages.

(7) Don't hang wires insulated or uninsulated on weak roof unless the roof is protected by adequate timbers.

(8) Don't hang wires, if it can be avoided, on collars supported by posts which are not set back in the rib. This applies especially to curves, where derailments are more frequent than elsewhere. Crossbars set in the coal are to be preferred. If this arrangement is not practicable, put heavy 3-in. plank at the level where the frames of the motor or the flaring of the cars would be likely to strike the timbers on derailment. Then block the timbers securely in place. The electrician would do well to note the condition of the track and timbers in such places.

On May 12, 1910, at the Blantyre Ferme colliery, belonging to Messrs. A. & G. Moore & Co., Scotland, a runaway car displaced some props, which brought down a girder. This cut a cable carrying a three-phase current of 400 volts, but as the neutral point of the system was connected to earth, the displaced girder was charged with only 230 volts. As the girder fell one end was caught on the cable; the other fell on a tie without making a sufficient ground. A workman tried to lift the girder and received a fatal shock. One recent explosion in England was alleged to have been the indirect result of the derailment of a motor. The motor tore down some posts and thus ripped down several feet of trolley wire. A dust explosion was said to have resulted.

(9) Don't omit to keep rubber gloves on hand on all motors and at all electrical pumps and substations for use in emergencies. On March 4, 1910, a motorman at Blackrigg No. 3 colliery of the United Collieries, Ltd., Scotland, got off his motor to work on an electric cable. The cable had a defective joint, which, being insulated by waterproof tape only, permitted the motorman to come in contact with the bare cable. A man offered to pull the motorman off, but this he would not permit. He instructed this man to shut off the current. This the latter failed to do, not knowing which switch to operate. Another man got some india rubber gloves and pulled the motorman off the wire. But by the time this was accomplished he was dead.

(10) Don't omit to ground properly all motor and generator bed plates, transformer coverings, mining-machine frames, boxes for inclosed switches and for junctions and such other exposed parts as are suitable for grounding.

On May 12, 1910, at the Auchengleich colliery, of Messrs. James Nimmo & Co., Scotland, a workman placed his hand on a transformer case in a longwall working. He was standing on an iron plate. The transformer took current at 400 volts and transformed it to 100 volts for use in lighting, the higher pressure being used for a conveyor operating along the face. It appeared that the cable had become worn at the brass bushing where it entered the case. The transformer case was thus electrified. The armoring of the cable might have served for grounding purposes, but apparently was so attached that it was not effective. The cable should be arranged so that there may be no stress on it where it enters the bushing or else a lug on the transformer should be connected to the armoring in such manner as not to be subject to any mechanical stress. A separate ground for the transformer would serve the purpose as well as any other method.

(11) Don't fail to ground the armor of your armored cables frequently, about every 300 to 500 feet.

(12) Don't omit to notice the condition of cables where two wires of different potential enter the cable.

(13) Don't omit to examine the openings or bushings of controllers, transformers, and switch boxes to see that the insulation of the entering cable has not been destroyed by rubbing.

(14) See that all switch boxes and all transformer cases completely inclose the conductors and wiring so that no inquisitive person is liable to be injured.

A boy at Bardykes colliery, belonging to the Summerlee Iron Co., Ltd., in Scotland, May 5, 1910, pushed a wire into a switchbox carrying 500-volt, 3-phase current with fatal results.

(15) Don't place naked live wires where, in oiling, the engineer or machine-runner may come in contact with them. The oiler may be able to turn off the current, but he may neglect to do so.

Employer's Liability Act

After almost a year's consideration, the U. S. Supreme Court, on Jan. 15, sustained the Employer's Liability Act of 1908. This act replaced one which had been declared unconstitutional, because it attempted to protect intrastate as well as interstate labor.

The act, thus sustained, abolishes the common law concept, which held that the employer was not responsible for the injuries inflicted by a coemployee. Interstate employees must now be defended in their work against the acts of their fellow servants.

Another interesting feature of the law is that it frees the employee or his dependents in some cases from facing the defense of "contributory negligence." In other cases it limits the effect of that doctrine.

The old common law regarded a contract of service as an agreement on the part of the employee to shoulder all the risks incident to that service if the dangers were known to him. The Supreme Court sweeps aside that common-law ruling and permits Congress to make laws which remove such consideration in the settlement of liability cases. No recent act is of more importance to the coal industry, than this latest ruling of our Supreme Court.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Questions for Beginners

Composition and Properties of Black Powder

Ques.—(a) What is the composition of black blasting powder? (b) What are the chief properties of this powder?

Ans.—(a) The theoretical composition of black powder is potassium nitrate (niter or saltpeter), KNO_3, 75%; carbon (charcoal), C, 12½%; sulphur, S, 12½%. Manufacturers, however, vary these proportions slightly and, in many instances, substitute for potassium nitrate the cheaper nitrate of soda ($NaNO_3$). The proportion of the several ingredients varies in different makes of black powder, as follows: Niter, from 74 to 77%; carbon, from 12 to 20%; sulphur, from 10 to 20%.

(b) The specific gravity of black powder varies from 0.89 to 0.94, so that a cu.ft. of the powder would weigh an average of $62.5 \times 0.92 = 57.5$ lb.; and 1 lb. of powder well rammed occupies $\frac{1728}{57.5} = 30$ cu.in. Exposed to dampness the nitrate salt dissolves, and the powder loses much of its strength. The soda powders are more susceptible to dampness than the niter powders. When powder is heated to 212° F. some sulphur is driven off and the powder loses some of its strength. At 668° F. the sulphur is ignited and the powder explodes. A good gunpowder ignited on a sheet of white paper should burn without blackening the paper.

Composition and Properties of Dynamite

Ques.—(a) What is the composition of dynamite? (b) What are the properties of dynamite?

Ans.—(a) Dynamite is nitroglycerin absorbed in some inert porous substance such as sawdust, wood pulp, or infusorial earth, which makes it less liable to accidental explosion when being handled. Nitroglycerin is a chemical compound formed by the action of nitric acid on organic matter. Its symbol is $C_3H_5(NO_3)_3$.

(b) Nitroglycerin is readily exploded by percussion or when heated to 250° F. The dynamite is wrapped in tough oiled paper, forming cartridges about 8 in. long and varying from ⅞ to 3 in. in diameter. The weight, in ounces, of an 8-in. dynamite cartridge is practically five times the square of its diameter in inches. Nitroglycerin freezes at —42° F., and when frozen is difficult to explode; exposed to a heat above 100° F., it evaporates freely, and the dynamite thereby loses its strength.

Tape Fuse in Blasting

Ques.—What is tape fuse?

Ans.—There are different kinds and grades of tape fuses adapted to the uses for which they are intended. These all consist of a continuous train of finely powdered gunpowder twisted or enfolded in paper, cotton, hemp, gutta-percha, or other similar covering. In coal mining, single- or double-tape fuse is commonly used, the latter being preferred because of its heavier coverings and better protection against injury in handling and tamping.

Gases Formed by Explosion of Powder

Ques.—What gases are formed by the explosion of black powder, and what is their relative volume?

Ans.—The principal gases formed are carbon dioxide, carbon monoxide and nitrogen, with varying smaller amounts of hydrogen sulphide, free hydrogen and marsh gas. These gaseous products vary with the conditions under which the powder is exploded.

The volume of the gases formed by the explosion of black blasting powder, measured at atmospheric pressure and a temperature of 32° F., is practically 360 times the volume of the original powder.

Pressure Due to Explosion of Powder

Ques.—What is the pressure that may be expected to be produced by the explosion of black powder in blasting coal? Show briefly how this pressure may be estimated.

Ans.—A pound of black blasting powder occupies about 30 cu.in. If this powder could be exploded instantly, in a confined space, the gases of the explosion would fill two-thirds of the space and have an estimated temperature, at the instant of explosion, of 3600° F. (the computed or theoretical temperature is 4400° F.). The remaining one-third of the space occupied by the powder is filled by the solid products remaining after the explosion. But the large grains of blasting powder burn slowly, in comparison; and, as a consequence, partial rupture of the coal occurs and expansion of the gases takes place with a reduction of temperature to about, say 2000° F., instead of 3600° F.

Since the volume of gases (at 32° F. and 14.7 lb. per sq.in. pressure) is 360 times the volume of the powder (30 cu.in.), there would be in this case $360 \times 30 = 10{,}800$ cu.in. of gas compressed into 20 cu.in. of space, which would increase the pressure in the ratio $\frac{10{,}800}{20} =$ 540 times. But the pressure is also increased by the rise of temperature in the ratio $\frac{460 + 2000}{460 + 32} = \frac{2460}{492} = 5$ times.

The total increase of pressure therefore may be estimated at $540 \times 5 = 2700$ times the original pressure, which, in this case, is $\frac{14.7 \times 2700}{2000} = 19.845$, say 20 tons per sq.in. The actual pressure may be more or less than this, according to conditions, but this may be assumed to represent a fair average, in mining coal.

Weight of Charge in Blasting

Ques.—What weight of black blasting powder should be used in blasting coal?

Ans.—The weight of a charge of powder to be used in breaking coal depends on the strength of the powder and the hardness of the coal, the thickness of the seam, character of the coal strata, size and depth of hole and its position in the seam. In general, these data vary so much that no hard and fast rule can be given, but experience alone must determine the weight of charge that will be safe to employ. The grade of powder used should be in accordance with the hardness of the coal. A shot is well placed when the depth of the center of the charge from the free face of the coal is about equal to the thickness of the stratum of coal to be removed by the shot, provided the coal is not undercut. The axis of the hole should always be inclined to the face of the coal, unless the coal is mined or sheared (sidecut); but always a line drawn from the center of the charge perpendicular to the axis of the hole should strike a face of coal in a distance less than the height of the coal.

If these rules are followed the weight of charge required will never exceed two pounds of black powder, or less, when one of the so called permissible powders is employed that is specially adapted to the coal in question. Approximately, 4 in. of a 3-in. hole, 6 in. of a 2½-in. hole, or 9 in. of a 2-in. hole will contain 1 lb. of powder well rammed.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

American vs. English Mine Fatalities

I want to say that I appreciate the article by James T. Beard on the death rate in the mines of the United States, per thousand men employed, in comparison with the same statistics in Great Britain. He states that the comparison should be on the basis of tonnage rather than on the basis of the number of men employed; and, using the figures in his table, I find for the same three years, 1908-1910, inclusive, the average tons mined per life lost in the anthracite district of the state of Pennsylvania was 134,047 tons, while in the bituminous district 247,318 tons were produced for every life lost. In Great Britain for the same period, I find the number of tons mined per life lost was 174,373 tons.

In comparing the production of coal in Pennsylvania with that in Great Britain, it would be manifestly unfair to consider the production in the anthracite field and attempt to compare this with the production for the same period of time in the bituminous mines of England, any more than we would attempt to draw a comparison between the anthracite and bituminous mines of Pennsylvania or any other state.

For example, the production of coal per life lost, 1908-1910, in the anthracite mines of Pennsylvania, is, as I have just stated, only 134,047 tons, as compared with 247,318 tons, during the same time in the bituminous mines of the state. The reason for this increased death rate in the mining of anthracite coal is to be found in the fact that every pound of anthracite coal must be mined by the force of powder. In Great Britain and in the bituminous mines of this country it is quite different, as the coal is undercut and less powder is required or used.

I have worked in the mines of Great Britain for twenty years and know what I am talking about in this regard. While there is considerable powder used in mining coal in Great Britain the amount per ton of coal mined is as nothing compared with the item in the anthracite district of Pennsylvania. The strength of these statistics is easily proved by comparing the tons of coal mined per life lost, in the anthracite district of Pennsylvania, with the same data in the bituminous district of the State, as I have shown above.

In the bituminous district of Pennsylvania 50 per cent. of the coal is mined with pick, while in the anthracite district every pound of coal mined is blasted with powder. Taking the average of the bituminous and anthracite mines, as Prof. Beard's figures clearly show, we have in the state of Pennsylvania 186,937 tons mined, for every life lost; while in Great Britain there were but 174,373 tons mined per life lost or, in other words, the production, including both anthracite and bituminous coal, in the state of Pennsylvania, per life lost, is still higher than the bituminous production alone, in the British Isles.

Pittston, Penn. W. D. Owens.

Timber Framing for Side Pressures

In reply to "Timber Foreman," in Coal Age No. 6, p. 188, I have found in framing for side pressures, that the ordinary notch invariably splits the cap, as shown in Fig. 1. This often happens before the post has taken the full weight of the side pressure.

Fig. 1 Fig. 2

Method of Framing

To avoid this, I have added 2 in. to the thickness of the leg and cut my cap at 45 deg. and the leg the same plus the batter. Then by nailing the piece cut from the leg in the corner, and driving two small track spikes in the cap and two in the leg, as shown at *N N*, Fig. 2, a strong durable joint is obtained.

This is a quick and simple way, and I have never known it to fail.

Joseph Virgin.

Plymouth, W. Va.

Textbooks at Examinations

In your issue of December 23 you advocate that aspirants be granted the privilege of using their textbooks at fireboss' and mine foreman's examinations. I cannot grasp your argument. Do you think that failure to pass is merely a sign of weakness of memory? To my mind, the defect is rather that the applicants for certificates don't try to memorize the rules, and they don't study enough to know the whys, the whens and the wheres from which those rules originate. I am of the opinion that the examinations should become more technical, so that those who desire to pass will read and study more. I think also, that a person seeking a certificate as fireboss should have at least ten years' practical experience in coal mines and he should serve two years as fireboss before being granted the further distinction of mine foremanship.

We are becoming more enlightened and progressive year by year. Yet we believe that a man can get a sufficient experience in a few years. We used to go to work with our fathers and learn by long experience what were the difficulties to be met with in mining and we would profit by what we were told. But now so short a period of time is spent in learning the problems at the face that there are many who are seeking certificates who have not materially benefited by others' experience or theories.

Moreover, even if the examinations are too trying mathematically for the practical man it must be admitted that all the examining boards deal leniently with him, believing that figures are less important than the facts of actual practice. They don't expect him, or themselves, to know all the latest developments of science or its more profound depths.

I should like to hear someone else express his opinions, someone who has worked such long shifts in the mines that his dinner bucket dragged the ground as he struck the trail for home after working for 10 or 12 hours, and who has nevertheless memorized the rules and formulas and needs no book in hand to solve the problems presented.

Iago.

Marion, Ill.

An Efficient Arrangement

In one of our gaseous mines where all hauling on the intake entries is done in the day time, we have found that a combination of steam jets and water sprays is the best method of laying the dust. When hauling is being done the water sprays are used. During the night, when haulage has ceased, the steam spray is turned on and the main entries and intake are thoroughly moistened.

Birmingham, Ala. Foreman.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Size of Rope, Deep Shafts

Please give me a formula for calculating the size of a wire rope that will be capable of hoisting a given load, say 5½ tons, including the weight of the cage, car and coal, making due allowance for the weight of the rope and friction, assuming a certain depth of shaft, say 150 yards. What is meant by factor of safety?

MINE FOREMAN.

Dunfermline, Ill.

Add one-tenth of the load to be hoisted, to allow for the friction of the hoist, which makes the total load at the end of the rope, in this case, $5.5 \times 1.1 = 6.05$ tons. The load on the rope at top of shaft is greater than this by the weight of the rope, which depends on its diameter (d), in inches, and the depth of the shaft (D), in feet.

Since the weight of a 1-in. wire rope is 1.58 lb. per foot, and the weight varies with the square of the diameter of the rope, the weight of any wire rope whose diameter is d is $1.58\,d^2$ lb. per lineal foot. The weight of the rope hanging in the shaft is then $(1.58\,d^2)D$ lb.; or for a shaft 150 yd. (450 ft.) deep the weight of rope is $1.58 \times 450 \times d^2 = 711\,d^2$ lb.; or dividing by 2000 to reduce to tons, $\frac{711}{2000}\,d^2 = 0.3555\,d^2$ tons. The total load on rope, including its own weight and the friction of the hoist, is then,

$$(6.05 + 0.3555\,d^2) \text{ tons.}$$

The breaking load of wire ropes depends, of course, on the material, as being iron, crucible or cast steel, extra-strong crucible steel, or plow steel. The strength of ropes, like their weight, varies with the square of the diameter. Here also, the strength must be calculated from the strength of the 1-in. rope, which is given below for different kinds of haulage and hoisting ropes.

BREAKING STRAINS OF DIFFERENT WIRE ROPES, 1 INCH IN DIAMETER

Kind of Wire	Breaking Strain, In Tons: Haulage Ropes, 6-strand, 7-wire	Breaking Strain, In Tons: Hoisting Ropes, 6-strand, 19-wire
Iron	16	17
Cast-steel	32	34
Extra-strong cast-steel	37	39
Plow-steel	42	44

Since the breaking strain of a 1-in. extra-strong, cast-steel hoisting rope, in the table, is 39 tons, the breaking strength of the same kind of rope whose diameter is d is $39\,d^2$.

The given working load, in this case, is $(6.05 + 0.3555\,d^2)$ tons. If we allow here a factor of safety of, say 6, which means the allowable working load is only one-sixth of the breaking strength of the rope, the breaking load would be $6(6.05 + 0.3555\,d^2)$ tons.

Then equating the breaking strength of the rope ($39\,d^2$ tons) with this breaking load and finding the value of d, we have for the required diameter of the rope

$$39\,d^2 = 6(6.05 + 0.3555\,d^2)$$

$$d^2(39 - 2.133) = 36.3$$

$$d = \sqrt{\frac{36.3}{36.867}} = \sqrt{0.9846} = 0.99, \text{ say } 1''$$

A 1-in., 6-strand, 19-wire, extra-strong, cast-steel rope will, therefore, be capable of hoisting a gross load of 5½ tons in a shaft 450 ft. deep, making due allowance for the weight of the rope and friction.

Mine Timber for Airways and Rooms

In our coal tract there is a considerable acreage of good oak timber, with a large proportion of hickory. We are anxious to use this timber to the best advantage in the mine. Will you kindly give us a little advice in regard to the cutting, storing and use of this timber in the mine?

MINE OPERATOR.

Oskaloosa, Iowa.

Mine timber should be cut in the winter months, from, say December to February, inclusive. The reason for this is that during this period of practically three months, growing timber contains less sap than at any other time of the year. Commonly, the sap ceases to run late in November and does not start again till late in February or early in March, depending upon location, exposure and progress of seasons. Timber cut during the period named is more readily seasoned and endures longer in the mine than timber cut while sap is running.

The cut timber is sawed or cut into lengths suited to the requirements of the mine, either at the time or shortly after cutting. Prop timber is best stored in a dry yard or shed, standing the posts on end, which allows better drainage and more complete seasoning than when piled in horizontal layers.

In cutting, as far as practicable, the large logs should be reserved for timbering shaft or slope bottoms, or landings and partings. The 6- and 8-in. timber make the most serviceable posts; the 4- and 5-in. sticks make good ties and the lighter 3-in. stuff can be used for lagging. Cap pieces should be 16 or 18 in. long, about 8 or 10 in. wide and 1½ or 2 in. thick. These should be cut from the waste ends of the large logs. All posts should be properly squared on each end.

The hickory timber should be used, as far as practicable, in rooms and other places, on cross-entries and temporary roads where the long life of the timber is not as necessary as on the main airways and haulage roads. A hickory stick makes a good room post. The oak timber should be reserved for all main roads and air-courses. Cap pieces should generally be made of the softer wood, and wedges of oak.

Mine rails for use in rooms must be sawed from large oak logs, selected carefully for their straight grain and freedom from knots. The size in common use is 2x4 in., in 12 and 16-ft. lengths.

Hospitals at Anthracite Mines

Will you kindly tell me if the Pennsylvania laws, with reference to hospitals, are observed in letter by the anthracite coal companies.

Philadelphia, Penn. W. R. C.

The hospitals of the anthracite mines of Pennsylvania fulfill not only the letter of the law, which compelled their establishment, but its spirit as well. The maintenance of good hospitals has become a matter of pride with the anthracite companies. The equipment is simple and easily kept clean. It usually consists of one or two tables, a reclining Morris chair, stretchers and a box of supplies, which is usually very much more complete than is required by the law. Wherever possible the underground hospitals are steam-heated, lighted by electricity, and provided with hot and cold water. The floors are cement and the walls whitewashed. In order that the injured may be carried to the hospital or to the surface with the minimum of discomfort, the Lehigh Valley Coal Company uses an ambulance car. The frame is similar to that of an ordinary mine car but the car body is supported by springs to reduce the jar of movement. Each car has two stretchers attached, also a seat at each end of the car for attendants.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Opinions have already been expressed here rather freely in criticism of the plan announced by the Lehigh Valley R.R. Co. for dealing with the stock of the Lehigh Valley Coal Co. in order to bring the present organization into conformity with the commodities clause of the interstate commerce law. A study of the details of the plan as announced in New York has led government officials to the view that whether the plan is legal or not, it will require a somewhat lengthy litigation to demonstrate its legality or the reverse.

In fact, there are a good many persons here who believe that it would be advisable for Congress to undertake further legislation on the commodities clause in order to make the meaning plainer and to give effect to the intent of those who originally framed the proposition. Such action has been suggested for some time past and in this connection it has been urged that the Department of Justice should draw up a provision embodying the commodities clause in a revised form and intended to cover the whole requirements of the situation as understood by the government today. It is decidedly doubtful, however, whether anything could be done on the subject at this session of Congress, and meanwhile attention will be given by the law officers of the government to the Lehigh plan as now stated, in order to determine whether or not it is incumbent upon them to seek a further test in the courts.

Scheme of Organization

There is a decided opinion among these officials that although the scheme is undoubtedly ingenious, it is, nevertheless, obviously a method of evading the plain intent of the law as understood here. The understanding of the scheme among those who have been devoting their attention to it is that under the new plan the coal company continues to hold and operate the coal mines as a corporation of the State of Pennsylvania and a new concern called the "Lehigh Valley Coal Sales Co." is organized. This coal sales company has no organic connection with the Lehigh Valley Coal Co., but is to make a contract with the latter, and by the terms of this contract, the sales company will purchase and sell such coal as may be owned or acquired by the coal company, whether already on hand, purchased or mined.

Meanwhile a dividend has been declared which is sufficient in amount to pay for the stock that the coal sales company will issue, and this stock will be apportioned among the railroad's stockholders. While, of course, the railroad stockholders will not be obliged to purchase the stock of the coal sales company, and provision will be made for issuing these shares through the intermediation of an underwriting syndicate, there will, nevertheless, thus be established a mining company with shares that are the direct property of the railroad, and this mining company will contract to sell its coal to a sales company whose stockholders, probably, will be almost identical with those of the railroad company.

A Parallel Case

An analogy has been drawn between this scheme and the situation created by the connection between the National City Bank and the National City Co. which was last summer held to be illegal by Attorney General Wickersham. This illegality was not charged on the ground of any direct prohibition contained in the national-bank act, but was based on the fact that the plain intent of the bank act was being defeated by means of the plan in question. It is alleged that the same objection would hold good in regard to this scheme in connection with the mining and selling of coal, it being said to be in direct contravention of the obvious intent of the commodities clause, whether or not against the letter of the law.

Oklahoma Coal Leases

Mr. Carter has offered a bill (H. R. 17,479) that grants to the coal-mining companies of the State of Oklahoma the right to acquire additional acreage adjoining their mine bases. The bill in part provides:

"That the Secretary of the Interior, under rules and regulations to be prescribed by him, may grant to any coal-mining corporation, individual, or individuals, operating a coal mine or mines in the State of Oklahoma, the right to acquire additional acreage from the unleased segregated coal land of the Choctaw and Chickasaw Nations, in the State of Oklahoma: *Provided*, That the land sought to be acquired adjoins and is contiguous to the coal-mining property in operation:

"Provided further, That the right to acquire such additional lands shall extend only to coal-mining corporations, individual, or individuals, actually operating coal mines in said state in good faith: *And provided further*, That the lease or leases on such additional coal lands shall not be made for a longer period of time than existing leases, and shall not be made at a less rate of royalty than the rate of royalty paid on existing leases now in operation in said State of Oklahoma."

Alabama

Birmingham — Consolidation of the Woodward Iron Co. and the Birmingham Coal & Iron Co. will not become effective until Feb. 1. The assumption of control by the Woodward company of the recently acquired properties of the Birmingham company is delayed to complete inventories and arrange a number of minor details.

Three hundred and fifty state convicts were removed, Jan. 1, from the Pratt mines of the Tennessee Coal, Iron & R.R. Co. to the Banner mines of the Pratt Consolidated Coal Co., and 250 county convicts were at the same time transferred by the latter company from Banner to Flat Creek mines.

The Sayreton mine of the Republic Iron & Steel Co. holds the state record for the largest production of coal in 1911. The record for output was previously held by the Flat Top mine of the Sloss-Sheffield company, which now ranks second.

Arkansas

Fort Smith—A statute making coal and railroad companies responsible for damages to employees from personal injuries due to the negligence of fellow servants has been upheld as constitutional by the Supreme Court of Arkansas.

Colorado

Cañon City—One hundred miners went on strike, Jan. 4, at the Ocean Wave mine of the Rocky Mountain Fuel Co., at Williamsburg, over differences arising in regard to the rate for removing "brushings." It is said the men have recently become organized by representatives of the union. After a general conference on Jan. 8, all but 40 of the strikers returned to work.

Denver—The state land board has granted a lease of coal lands to R. W. Dymond, of Denver, reserving to the state the right to dictate the price at which coal shall be sold from the land. This is

the first time in the history of Colorado that the state has undertaken thus to fix prices. Dymond will be permitted to sell the coal at 50c. profit per ton. The board will fix the absolute price after finding out how much it costs to mine the coal. The lease applies to 640 acres of coal land near Como.

Erie—So far as can be learned there is no change in strike conditions here, but it is said there is evidence that matters are shaping themselves for a big strike in the southern part of the state. If this is so, there will be no settlement of the Erie strike, and the mine owners are working on this theory.

Illinois

Bloomington—A serious coal famine exists in most of the smaller towns of central Illinois and mines here are besieged with orders.

Staunton—One man was killed instantly, another injured and a half-dozen others, all miners, had a narrow escape in a cave-in, Jan. 6, at the De Camp mine, near here.

Du Quoin—Six prospect holes have been drilled on a 17,000-acre tract of coal land near Waltonville, about 15 miles east of Sunfield and north of Christopher. These show a seam of coal ranging from 6 ft. to 7 ft. 6 in. in thickness, and the property owners have appointed a committee to arrange for the sale of the land.

Carlyle—Tests for oil have revealed the existence of large beds of coal to the west and north of here. The coal has been found at depths ranging from 400 to 425 ft. The veins range from 5 to 12 ft. thick, and in some places two seams 6 ft. thick have been found. The tests indicate that the townships of Carlyle, Santa Fe, Wade, Wheatfield and Irishtown are underlaid by unusually large deposits.

Chicago—It is understood that the Illinois coal operators have joined the American Mining Congress in a body. This means the addition of about 100 members and involves an educational fund of $2000.

Indiana

Indianapolis—The official call for a joint wage conference of coal miners and operators from throughout the coal-producing regions of the United States was issued here, Jan. 11. The conference will convene here on Jan. 25. Miners and operators from Indiana, Illinois, Ohio, Pennsylvania and West Virginia will be represented. Wage contracts in practically all bituminous and anthracite regions expire on Apr. 1. More than 400,000 miners, a large number of whom are members of the United Mine Workers, will be affected. The wage conference will be held in connection with the annual convention of the United Mine Workers.

Brazil—Brazil coal operators are receiving appeals for coal from many cities that are experiencing famines. Rushville and several cities in eastern Indiana that have been depending on natural gas are out of coal. All the mines of this section, which have been running but half time all winter, are now working full time and giving employment to every miner who can be engaged. Much trouble is being experienced by the coal companies in moving the coal on account of the snow and the intense cold.

Iowa

Chariton—J. F. Spiker is negotiating with the Albia Coal Co., of Albia and Oskaloosa, in regard to leasing about 3000 acres of coal land in Lucas County to that company. It is reported that development in this region may be expected in advance of the completion of the new line of the Rock Island R.R.

Kentucky

Henderson—The property of the Southern Coal & Transportation Co., consisting of about 8000 acres of coal rights, together with developments and equipment, was bought by M. V. Denton at a public sale at Robards, Jan. 1, for $93,-335, the appraised value being $140,000. It is reported that the Panama Coal Co., composed of M. V. Denton, O. W. Rash and others, will operate the mines.

Madisonville—The Reinecke Coal Mining Co. has sold its coal mine and property near Madisonville to the Clear Creek Coal Co. The property transferred is one of the largest producing coal mines in the state. It employs about 200 men and has an admirable uptodate equipment. The grantee is a corporation recently organized by Eastern capitalists to take over this and other properties in western Kentucky. There will be no change in the management or operation of the Reinecke mine for the present.

Minnesota

Wells—While digging a trench on the farm of Henry Menerich, of Mansfield township, workmen found a vein of lignite coal of excellent quality. The depth at which the coal was found was about 12 ft., and investigations will be made to ascertain if there is coal in sufficient quantities to warrant mining for commercial purposes.

Missouri

St. Louis.—Contemplating an extension of the Southern Traction Co. being constructed from St. Louis to Belleville, from the latter city to the rich coal fields of southern Illinois, and the completion of the St. Louis and St. Libory road through the southern portion of St. Clair County, the Donk Brothers Coal & Coke Co. of St. Louis, is buying up extensive coal rights in St. Clair, Randolph and Washington Counties, principally north of the Illinois Central Railroad. The company is said to have made exhaustive borings in southern Illinois, where it is operating, and, while the officers have made no statement as to how they expect to reach the St. Louis markets, it is said they are depending on the extension of the Southern Traction Co. lines, which will probably interlace the rich mining and farming lands near Marissa, Tilden and other St. Clair, Randolph and Washington County towns. There is also a report that the Mobile and Ohio Railway is considering the construction of a branch line from Sparta to Marissa.

Montana

Three Forks—That coal in large quantities may underlie the Gallatin valley is indicated by the discovery here of a 7-ft. vein of what appears to be an excellent grade of coal. The discovery was made recently by well diggers on the property of the Milwaukee & St. Paul R.R.

Helena—Argument was concluded Jan. 6 in the case of the Montana, Wyoming & Southern Ry. Co. against the Montana Railroad Commission. The railroad seeks to restrain the commission from reducing the rate on coal between Bear Creek and Bridger from 45c. a ton to 35c., on the ground that the lower rate is confiscatory. The Bear Creek operators contend that they cannot compete with operators of other districts if the higher rate remains in effect.

Ohio

Wellston— Foreign capital, interested by B. F. Howland and C. F. Butterfield, of New York, and E. B. Bingham, of Toledo, will subscribe to most of the stock of a company to be organized at Wellston, for the purpose of developing southern Ohio timber and coal lands and completing a railroad to Lake Erie. For a number of years the men behind the deal have held options on coal and timber lands in Jackson and Scioto Counties. They report having raised $8,000,000 for a railroad from Portsmouth through Wellston to Lake Erie at a point near Sandusky.

Bridgeport—It is understood here that the proposed $25,000,000 merger of eastern Ohio coal properties will be consummated in February, although it is claimed that the merger has been deferred until a decision is reached in the case of the Pittsburg vein coal operators of district No. 8 against the Pennsylvania and Wheeling & Lake Erie railroads. It is said that in the event of a decision unfavorable to the operators, the merger will fall through.

The Lorain Coal & Dock Co. plans to make extensive improvements to its mines

at Crescent, including the erection of a large steel tipple. The work will be started in the early spring.

Columbus—The legal battle of the State of Ohio for exclusive power over freight and passenger rates within its borders opened at Washington, D. C., Jan. 10, when Attorney General Hogan, of Ohio, filed a brief in the U. S. Supreme Court supporting the right of the state to fix rates on coal from certain mines in Ohio to Lake Erie ports within the state. The railroads contend that the coal is not destined for lake ports, but is a part of interstate shipments. The case is set for oral argument on Feb. 19.

The Capitania Development Co., of Toledo, has been organized with a capital stock of $10,000, which, however, is to be largely increased in the near future. The officers of the company are Thomas H. Tracy, of Toledo, president; George M. Jones, of Toledo, vice-president and treasurer; J. J. Robinson, of Toledo, secretary. The men interested in the new company have purchased 21,500 acres of undeveloped coal lands in Belmont County and also the Ohio River & Western R.R. Co., operating a steam line of 112 miles from Zanesville to Bellaire. The purchase price is said to have been $3,000,000. The railroad, now a narrow gage, is to be made standard gage at once and two mines will be opened this spring. The plans of the company contemplate the opening of two new mines each year for some time.

Pennsylvania

Bituminous

New Castle—Two men were entombed and probably killed, Jan. 9, in the cave-in of a small mine, eight miles west of here.

Monongahela—The mines at Van Voorhis, Acme, Ellsworth and Cokeburg are in operation, and are making fairly good time. At Marianna the mines average about three days a week. Hazel Kirk No. 1 and Dunkirk are idle for the present.

DuBois—The new Chickasaw mines of the Shawmut Mining Co., among the largest and most complete in this section of the country, have been organized by the United Mine Workers and will work under their agreement. It is said that the capacity of these mines will be about 2500 tons daily.

Portage—The Puritan mine, now owned by the Martin Coal Co., resumed operations, Jan. 15, on an extensive scale. The company was recently awarded $74,323 in a suit against the Pennsylvania R.R. Co. for alleged discrimination in the distribution of coal cars.

Tyrone—The U. S. Circuit Court of Appeals has refused to set aside the judgment of the Circuit Court awarding $62,658 damages to seven coal companies operating in the Clearfield district in their suit against the Pennsylvania R.R. Co. for rebates and concessions granted competitive companies.

Connellsville — The Thompson - Connellsville Coke Co. has closed a contract with the Inland Steel Co. for 15,000 tons of coke per month. This contract, together with that of the Connellsville company with Jones & Laughlin and others, will take the entire output of the plant and its 800 ovens will be kept in full blast to supply the demand.

Uniontown—The hearing of the case of the Independent Coke Producers' Association of Uniontown against the Baltimore & Ohio and other railroads before the Interstate Commerce Commission, which was scheduled to be called on Jan. 15, at Washington, D. C., has been indefinitely postponed.

Anthracite

Scranton—President Truesdale, of the Lackawanna R.R., admitted, Jan. 10, that the demands of the coal miners, who are threatening a strike, have been received by the operators. He announced that the request of the miners for a conference on the wage scale would be granted and that the meeting would probably be held some time in February.

Wilkes-Barre—The Conyngham colliery of the Delaware & Hudson Coal Co., at North Wilkes-Barre, has resumed operation after being idle for nearly three years following the abandonment of the old breaker. Coal is now carried underground by electric haulage to the company's No. 5 breaker.

While engaged in timbering in the No. 9 slope of the Parrish colliery, of the Parrish Coal Co., Plymouth, in the afternoon of Jan. 9, six men were instantly killed and two severely injured by an explosion. Colliery officials say that the explosion was one of dynamite, but are at a loss to explain how dynamite came to be stored in the slope.

Pottsville—Preparations are now under way to tap a vast underground body of water that is backed up in the old abandoned workings of the Maryd colliery, in the Schuylkill valley, near Tuscarora. A large area of virgin coal will then be mined.

It is reported that the Philadelphia & Reading Coal & Iron Co., aroused by recent fires, has started to equip all its mines and collieries with telephone service.

Washington

Centralia—A 12-ft. vein of coal has been discovered underlying the 40-acre farm of D. W. Leonard, just east of Centralia. The coal appears to be of a superior quality to any yet discovered in this vicinity, and Mr. Leonard is casting about for means to start mining operations and place the coal on the market. The property is only a few hundred feet from the Centralia & Eastern R.R., and near the mines of the Mendota Coal Co., thus making the situation particularly advantageous for mining and marketing the fuel.

West Virginia

Fairmont—Heroic work by miners recently prevented a large loss by fire to Consolidation Coal Co. property, at Montana. Breaking out from an unknown origin the flames destroyed the blacksmith shop at the mines and for an hour threatened the tipple and opening. The tipple was but slightly damaged while the opening was protected. The loss is estimated as being in the neighborhood of $1200. The Montana mine, which is one of the pioneers of the region, has been unfortunate with fires.

Morgantown—The Consolidation Coal Co., of Fairmont, recently made the location for a shaft on the O. J. Eddy farm, about six miles up Indian Creek. This is a part of the Millholland tract of coal land, aggregating something like 12,000 acres, taken over by the Consolidation Co. several years ago. Prospects are good for the development of these valuable coal lands immediately upon the completion of the Buckhannon & Northern and the extension of the Monongahela R.R. to the state line.

Wyoming

The United States Circuit Court of Appeals, Jan. 13, condemned the practice of using dummy entrymen to obtain for a corporation more than its proper share of public lands. In the case of the Owl Creek Coal Co., it was alleged that 14 individuals had filed entries on 1760 acres of government coal land for the purpose of turning the property over to the corporation. The lower court had released the defendants, but the court of appeals reversed this decision on the ground that it would invalidate the whole act prohibiting such practice.

Canada

British Columbia—Officials of the United Mine Workers of America are at Vancouver Island, organizing a new district of mine workers.

New Brunswick—On Jan. 11, Sir Thomas Tait took over control of the Frederick & Grand Lake Coal & Ry. Co. Extensive plans will be carried out for the development of the Grand Lake coal areas, including the building of a railway for 30 miles from Gibson to Unito for supplying the Canadian Pacific Ry. with 10,000 tons of coal annually. Construction work on the railroad will be started early in the spring.

Personals

E. L. Booth has been elected president of the Empire Coal Co., of Montreal, Canada. Mr. Booth was formerly second vice-president in charge of the Chicago offices.

Edward M. Mancourt, formerly manager for the Consolidation Coal Co., in Detroit, has been appointed general western manager for the company, with offices in Chicago.

O. H. Reinholt severed his connection with the U. S. Bureau of Mines, Jan. 14, at the expiration of leave of absence, and will resume private practice as a mining engineer with headquarters at San Diego, Calif.

Charles C. Renshaw, for a number of years manager of the Altoona Coal & Coke Co., has become identified with the firm of Tatnal, Lee & Co., Philadelphia, Penn., with offices in the Stephen Girard Building.

W. H. Loomis, lately with G. B. Markle & Co., at Jeddo, Penn., has become president and general manager of the Rock Hill Coal & Iron Co., following the separation of this company from the East Broad Top R.R. Co.

J. E. Leonard, of the Chehalis Coal Co. was in Spokane recently and exhibited samples of some exceptionally fine coal, taken from his Coal Creek mine. The coal is as nearly of a true bituminous quality as any yet found in western Washington.

Sam Dixon, president of the New River Coal Co. and of the White Oak Ry. Co., recently appeared before the Interstate Commerce Commission, at Washington, D. C., in connection with a complaint against the Chesapeake & Ohio R.R. in regard to the apportionment of rates.

Dr. M. J. Shields, of the American Red Cross Society, is now introducing first aid on the lines of New York Central, the New York, New Haven & Hartford and the Lackawanna railroads entering New York City. He is accompanied by Dr. Mackey, formerly of Scranton, Penn. On completion of this work, Dr. Shields intends to take his car to Washington, D. C., and will there attend the International Meet of the Red Cross Society.

Obituary

E. S. McKinley, Jr., general superintendent of the Oak Creek Mine, of the Yampa Valley Coal Co., was killed recently at the mine by falling on the tracks in front of a loaded car and being crushed beneath the wheels; he died while being rushed to Denver on a special train. Mr. McKinley was 28 years of age and a graduate of Cornell University in mechanical engineering. His death is deeply regretted in Denver, where he was widely known and greatly esteemed.

Construction News

Bridgeport, Ohio—The Lorain Coal & Dock Co. plans making extensive improvements at its Crescent mines, including the erection of a new steel tipple. Work will be started early in the spring.

Pittsburg, Penn.—The Pittsburg Coal Co. is taking bids for the sinking of two shafts: one, approximately 136 ft. deep, on the Jones Ray farm, and one, approximately 151 ft. deep, at the Yough Slope Mine. Plans and specifications are on file at the office of the chief engineer, Oliver Building, Pittsburg.

Bids are being taken on buildings and equipment for the new plant of the Cross Creek Coal Co., Nurgettstown, Penn., which includes: A new tipple; power house, 50x100; boilers of 1200 hp., coal picker, stokers, electric generators, fan and ventilating plant, pumps, motors; railway and mine trackage and electric mining machinery.

Fort Collins, Colo.—The Fort Collins Mining & Coal Co. has increased its capitalization from $50,000 to $150,000 and expects to sink a shaft and install complete mining equipment for operation within the year.

Castle Rock, Wash.—H. B. Davies and associates, of Tacoma, have leased the Huntington Coal property, two miles south of here, and will equip it with modern machinery for operation on a large scale.

E. N. Ouimette, of New York City, and associates, are reported to contemplate the erection of a $300,000 briquetting plant near Castle Rock.

Medford, Ore.—Pierce, Manley & Wallace, of Seattle, Wash., have purchased the Cascade Mine and will install new machinery.

Birmingham, Ala.—It is reported that the Tennessee Coal, Iron & R.R. Co. will build 50 miners' houses at Mine No. 2, near Ensley, and about 200 houses at Mine No. 12.

Columbus, Ohio—The Capitania Development Co., of Toledo, has been incorporated with $10,000 capital stock, which will be greatly increased in the near future. Men interested in the new company have bought 21,500 acres of coal land and the Ohio River & Western R.R. Co.'s 112 miles of narrow-gage track from Zanesville to Bellaire. Railroad will be made standard gage at once and two mines opened this spring. Plans contemplate the opening of two mines each year until property is fully developed. Thomas H. Tracy, Toledo, is president.

Victoria, B. C.—The Canadian Collieries (Dunsmuir), Ltd., will expend $750,000 during the next year for additions to its plant and machinery and for further development of its coal properties. This will be in addition to contracts which the company has recently awarded in connection with a hydro-electric power plant project.

Recent Incorporations

St. Louis, Mo.—The Sterling Coal & Mining Co.; capital, $60,000. Incorporators: S. A. Meddaugh, H. Brown and A. B. Rushton.

Toledo, Ohio—The Capitana Development Co., to own and operate coal mines in various parts of Ohio; capital, $10,000. Incorporators: George M. Jones, James J. Robinson and John Craig.

Austin, Tex.—The State Lumber & Coal Co., of Texas City; capital, $15,000. Incorporators: F. J. Marett, J. M. Proctor and J. Stanley Carothers.

Dover, Del.—The Clear Creek Coal Co., to operate coal mines in Kentucky and market coal; capital, $100,000.

Wheeling, W. Va.—The Spruce Bend Coal Co., of Bend, W. Va., to mine coal and manufacture lumber in Logan County; capital, $200,000, of which $10,000 has been subscribed and $1000 paid. Incorporators: P. M. Sharples, and others of West Chester, Penn.

The Arcadian Coal Co., to mine and develop coal and mineral lands and manufacture lumber in Braxton and Webster Counties, W. Va.; capital, $200,000. Incorporators: Thomas McCabe, Cleveland, Ohio; M. J. Sullivan, Latrobe, Penn., and others.

Wilmington, Del.—The Gordon Coal Co.; capital, $1,000,000. Incorporators: M. B. Hughes and J. G. Gray, of Philadelphia, Penn.

Columbus, Ohio—The Dean Coal & Coke Co., to mine and sell coal and coke; capital stock, $10,000. Incorporators, S. E. Dean, J. A. Stalter, J. R. Elder and others.

Montgomery, Ala.—The Nauvoo Consolidated Coal Co.; capital stock, $12,000. Incorporators, R. S. Shook, A. S. Tubb and E. M. Martin.

Foreign News

England—The final ballots of the English coal miners for or against a national strike, which will affect 900,000 men, were cast Jan. 12. The results will show a vote overwhelmingly in favor of a national stoppage. Reports indicate that fully 80 per cent. of the men have gone on record as favoring a strike. A full month, however, must elapse before the strike can become effective, as the miners are under agreement to give notice before stopping work.

Miners' Convention

Special Correspondence

Division of opinion as to the policy to be pursued by the bituminous and anthracite coal miners' unions of the country in attempting to enforce a demand for higher wages appeared among the leaders of the United Mine Workers of America when its annual convention opened in Indianapolis, Jan. 16. Some 1300 delegates representing 300,000 miners were present.

The question, which will be brought before the convention, is whether the individual districts of the miners' general union shall sign new wage contracts with mine owners, as they can be negotiated, or whether the miners as a national organization shall refuse to sign any contracts until the operators of all the districts have agreed to the miners' terms.

President White's Report

President John P. White in his annual report, said that the new wage contracts with the mine owners, to go into effect on Apr. 1, made it necessary for the United Mine Workers to put aside internal dissension and prepare to struggle for advancement.

"So far as I am concerned, and I think I voice the sentiments of the rank and file, it is my opinion that our policy should be such as to leave no doubt in the mind of anyone that there will be no reductions from existing wage contracts, and we should earnestly strive for such advancements as it is within the range of possibilities to secure. While we will never surrender the right to strike, we should not lose sight of the fact that some of the greatest successes our organization has ever achieved lay in the channels of peace."

Of the condition of the union in the anthracite field largely in Pennsylvania, in the present crisis, President White reported: "The problem of organizing the anthracite mine workers and building up a strong organization in that field has been a matter of serious concern to our movement for many years. The small membership reported in the anthracite field indicates that the miners are indifferent to their surroundings."

Interstate Agreement

The president reported that efforts were under way to bring about a joint conference between miners and operators of the bituminous fields of western Pennsylvania, West Virginia, Ohio, Indiana and Illinois, to discuss the terms of the new wage contract, at the close of the present miners' convention.

While he declined to commit himself in the matter, Vice-President Frank J. Hayes said that opposition to the policy of a national strike will come largely from officials of districts bordering on unorganized coal fields.

"It must be remembered that while the United Mine Workers have a membership of nearly 300,000, there are about 450,000 coal miners that are unorganized," said Mr. Hayes. "The question as to whether we should hold out for a national agreement, though in some districts the operators come to our terms, is a serious one."

Anthracite Miners and Operators

Special Correspondence

The demands of the anthracite miners, as formulated at the three-district convention in Pottsville last fall, are now in the hands of the operators. The miners' representatives have asked for a conference with representatives of the operators, to be held some time in February, and in all probability such a meeting will take place in New York or Philadelphia at the time indicated.

President William Truesdale, of the Lackawanna Coal Co., was in Scranton recently, and in the course of an interview, said: "I have no objections to meeting representatives of the miners' union," carefully indicating, however, that he spoke only for himself. Nevertheless, it may be accepted as a fact that the operators will offer no objections to negotiating with the men who are union officers, and there will thus be avoided the useless delay and uncertainty which prevailed three years ago, when the operators at first refused to deal with the officials of the miners' union, as representing the body of workmen.

As has been frequently stated, the miners have made a series of demands in which the principal items are as follows: (1) Recognition of the union with the introduction of the "check-off" system; (2) a 20 per cent. increase in wages; (3) a one-year agreement; (4) payment for coal by ton instead of by car, wherever practicable; (5) an eight-hour day. There are also a number of secondary demands, but these will hardly be taken into consideration during the course of negotiations.

It should be stated that the operators have permitted it to become definitely known that the majority of these demands are not likely to become the basis of a new agreement. The "check-off" system is particularly obnoxious to the operators, and it may also be stated that it is not desired by the great majority of anthracite miners.

On the other hand, it is understood that the operators are willing to make some substantial concessions to the miners on the basis of the existing agreement, and in all probability they will have their way in this, as the union is scarcely in a position to inaugurate and sustain a prolonged strike. It has exaggerated its demands, and it may be anticipated that the operators will at first exaggerate their determination to grant no concessions, but unless some unforeseen contingency arises, it now seems probable that a satisfactory compromise will be reached without involving a strike.

Institute Meetings

The Y. M. C. A. mining institutes of the Pennsylvania anthracite region now have an aggregate membership of over 5000 mining men. Meetings have recently been held in several important districts.

Wilkes-Barre—Two interesting papers were presented at the institute meeting held here on Saturday, Jan. 13, one on "Timbering," by John L. Picton, and one on "Who is a Miner?" by Richard Lewis. H. G. Davis, president of the Wilkes-Barre district, presided. The attendance was gratifyingly large, and the discussion most interesting.

Pittston—The third meeting of the Pittston district institute was held Monday evening, Jan. 15, and the subject for discussion was introduced by a paper on "Transportation," read by S. J. Jennings, general inspector for the Pennsylvania and Hillside companies. Questions of general interest were answered by Tudor Aston, foreman of Mt. Lookout colliery; John T. Brown, inside foreman for the Erie company, and Edward C. Weichel, general inside superintendent, Butler colliery.

Carbondale—On Saturday, Jan. 13, the Carbondale district mining institute held its annual banquet, at which 360 members were present. Two hundred members were added to the roll during a recent campaign. C. L. Fay, of Wilkes-Barre, was toastmaster, and other speakers were as follows: P. J. Moore, state mine inspector and president of the institute; Charles Enzian, U. S. Bureau of Mines; Dr. J. W. Grant, Carbondale, and Mr. Thomas, district superintendent for the Delaware & Hudson company, at Olyphant.

Nanticoke—At the meeting here, on Saturday, Jan. 6, papers were read before the Nanticoke district mining institute by William Norton, mining engineer of the Alden Coal Co., and P. F. Devers, district superintendent of the Lackawanna company. John E. Thomas, of the Susquehanna Coal Co. and president of the institute, presided.

Shamokin-Mt. Carmel—The institute of this district held a meeting on Thursday, Jan. 11, at Shamokin, at which J. R. Holland, general foreman of the Mineral R.R. & Mining Co. and president of the institute, presided. Papers by John Allen and J. W. Weir were followed by a general discussion and a musical program.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The continuation of low temperatures generally throughout the country has placed the coal business in the strongest position it has been in this season. The prolonged summer, with high temperatures prevailing well into the fall, resulted in a light buying movement and a consequent shortage in supplies. The cold weather of the past two weeks, together with the prospects of labor troubles, and some difficulties in transportation, have caused heavy inroads to be made on all available sources of supply, and these have been seriously depleted.

On the Atlantic Coast there has been considerable heavy weather, causing some losses at sea and making arrivals slow; the demand is strong, and with supplies low, it is probable this market will continue active the remainder of the season. In Pennsylvania and Ohio the trade is active and strong, especially in slack. The movement has been slow and some roads are reported as storing in anticipation of a strike; however with their privilege of confiscating any fuel in transit, it is not believed that they will consider it necessary to lay in heavy supplies. The West Virginia operators are viewing the situation with complacency, not only because of the possible labor troubles here but abroad as well; inquiries have been received for coaling the British navy and hopes are entertained of securing some of the English export trade in event of trouble there.

The market in the Middle West continues strong and active with prices advancing and stocks low. The prospects of a famine, as reported in some instances, do not seem probable, as warmer weather will permit the movement of heavy tonnages now standing on side tracks. Colder weather has caused renewed activity in the Western trade, but supplies are reported good and no famine is expected.

Boston, Mass.

The continued cold is having the usual effect on a market already short of supply. The two days, Jan. 13 and 14, were the coldest in this vicinity for five years.

Bituminous arrivals have been further interrupted, there have been some losses at sea, and conditions generally are materially worse than a week ago. Were it not that practically every consumer, small and large, is under contract, we would have a lively spot market. As it is, every shipper is looking for temporary supplies, and merchants are working together in spreading around what coal is available. Prices are unchanged, from around \$4 on cars, but chiefly for the reason that almost no free coal is to be had. Slow loading is reported from the Virginia terminals.

In anthracite there is no improvement. Dealers have tried to be forehanded, but are now hardly able to get more than hand-to-mouth shipments. With a strong retail demand there is little chance to accumulate stocks, as the prudent ones were hoping to do at this time, and an active request between now and Apr. 1 can be put down for certain. Stove and chestnut, as well as the supply of barges, are short, and the delays are getting more and more protracted. The Susquehanna Coal Co. lost the barge "Wayne" in Boston Harbor, on Jan. 13, and other transportation has suffered in the heavy weather.

The Boston retailers advanced broken and egg, Jan. 15, to \$7 and \$7.50, in each case 25c., making egg the same price as stove, and broken only 50c. less. Water freights are somewhat firmer, \$1@1.10 being asked for the larger craft, Hampton Roads to Boston, but with rather few inquiries for so short a market.

New York

The continued cold weather has made market conditions here considerably firmer. There has been an increase in the spot demand, particularly for the better-grade steam coals, for which there is a ready demand at a price of 10c. a ton higher than was offered last week, without finding a market.

All of the New York piers are having a great deal of difficulty in dumping coal with the result that boats are accumulating and the work of loading is some two or three days behind. There is now some demand for loaded cargoes at prices somewhat above the quotations at which f.o.b. coal can be had. When the cold wave started the market here was rather heavily supplied with coal at the piers so that the slowing up of transportation, caused by severe weather conditions, is only now beginning to show, in a shorter supply at the piers.

Spot prices for steam coals f.o.b. New York, range about as follows: West Virginias, \$2.50; ordinary Pennsylvanias, \$2.60@2.70; better grade Pennsylvanias, \$2.80; with the best grades of Pennsylvania \$2.90@3 f.o.b. The high-grade coals are unusually scarce and the market for these is quite firm. There are apparently no accumulations of demurrage coal of any grades at the piers.

Pittsburg

Bituminous—The severe cold snap has seriously disarranged the movement of coal, the temperature having been frequently below zero in the past few days. This has affected both mining and transportation. Mines have been short of cars, have been unable to mine their full quotas, and the coal has moved slowly after loading. For illustration, a case is mentioned of a coal train, such as would ordinarily be moved with one locomotive, which was stalled with four. A few mines are shut down entirely from lack of cars, while others are behind in deliveries and are having a great deal of difficulty in apportioning their output to apply on their different contracts.

Several coal companies on the main line of the Pennsylvania have received communications on behalf of the coal department of the British Navy, indicating that it may be in the market for coal against the possible suspension of mining in England, March 1; on account of the pending difficulty here, such inquiries do not elicit much interest.

Occasionally specially high prices are paid for small lots of coal, chiefly carloads, but in general the market is not quotably changed and we continue to quote: Nut, \$1.05@1.10; mine-run, \$1.10@1.15; ¾-in., \$1.20@1.25; 1¼-in., \$1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg district.

Connellsville Coke—Spot furnace coke continues scarce, and no coke has been sold below \$1.80 in the past week, while higher prices have frequently been paid for small lots. Under normal conditions the shortage in production due to the holidays would be over by this time, but the cold weather has given production a fresh setback, and there is the great difficulty in moving coke besides. Nothing has been done on contract. We quote: Prompt furnace, \$1.80@1.90; contract furnace, \$1.85@1.90; prompt foundry, \$1.90@2; contract foundry, \$2.10@2.25.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Jan. 6, at 322,906 tons, an increase of 29,000 tons, and shipments at 3314 cars to Pittsburg, 4955 cars to points West and 826 cars

to points East, a total of 9095 cars, a gain of 700 cars.

Baltimore, Md.

Prevailing zero weather, with all of its discomforts, gave Baltimore operators the opportunity to have their inning during the past week. Prices of all grades of coal advanced from 10c. to 15c. per ton over those obtained for weeks past, and the demand for the product was unusually heavy.

The low grades of coal, which heretofore sold at from 70c. to 80c., advanced to from 90c. to $1 per ton, and were hard to procure at that figure. The best grades of small-vein coal advanced from $1.10 to $1.20 per ton and the supply was limited. The big-vein Georges Creek coal also jumped in price, the trade receiving $1.75 for all that it could deliver.

The movement of coal has not been all that could have been desired, on account of extreme weather conditions, and operators were careful not to book any more orders than they could reasonably care for. Ice conditions in the Patapsco River and Chesapeake Bay have been serious for days, and but few vessels have ventured out. At the coal piers of the Western Maryland Ry. Co., located at Port Covington, several hundred carloads of coal stood on the tracks untouched, and a considerable portion of it could not be loaded into vessels until it had gone through the steaming process. Shippers are hoping that the ice in the river and bay will disappear sufficiently to permit vessels to ply between destined ports.

Buffalo, N. Y.

There is a special complaint this month from the bituminous trade. There has been a great abundance of cold weather and the volume of business is large, yet the utmost effort on the part of operator or jobber, has failed to advance prices. The inference is that there is always someone willing to sell coal down to cost or the next thing to it. In fact a leading operator said the other day that he was obliged to sell his coal for less now than he received for it last summer. He had always been used to a low price in summer, counting on making his profit in the winter months, but he has so far been unable to get an advance and he finds that others are telling the same story.

There is a somewhat stronger feeling in slack and the increased strength of coke continues. If the improved tone of the pig-iron trade is kept up there ought to be a way before long for the bituminous trade to command a higher price. Quotations continue at $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack. Coke ranges from $4.25 for best Connellsville foundry to $3.50 for stock coke. The Allegheny Valley mines are running fairly strong, coal prices being about 25c. less than Pennsylvania.

The demand for anthracite is again away in advance of the supply, there being all of the early shortage of stove, which is already giving out in the Western market. The mining has been slow since the beginning of the holidays, so that the dealers are quite unable to supply their customers. All mining has been slow this month and in some instances the outside operations have been suspended on account of the weather.

Cleveland, Ohio

In the past week there has been a tremendous scramble for domestic coal, slack, and also railroad fuel. The railroads have been confiscating a great deal of coal for their own use which, in consequence, has hampered this market materially.

Slack has reached the $1 mark the past few days, with little in sight. The weather in the past week has been the severest for a number of years, and while there has not been any actual suffering for the want of coal in the city and vicinity, there was considerable uneasiness on account of so much coal being confiscated and the railroads slow in making deliveries.

The inquiries for coal have been greater in the past week than at any time during the year. Of course, this has been caused from the unusually severe weather. Prices have been firm, but no material advance, excepting in slack, has taken place.

Columbus, Ohio

With the thermometer hovering around the zero point and often reaching 10 deg. below, and with an improvement noted in many lines of manufacturing, the coal trade in Ohio is now in better condition than at any time in the past six months. Activity prevails in every branch of the trade and operators and jobbers are having difficulty in filling orders promptly because of the lack of motive power on the railroads and a growing scarcity of cars.

The domestic trade is the chief feature in the market at this time. Dealers went into the cold spell with fairly large stocks, but the demand was so strong that they were soon exhausted and orders were placed with the operators and jobbers. Soon immediate delivery was asked and in some instances stocks were difficult to obtain.

Railroads have been unable to move coal shipments promptly because of the heavy snow and extreme cold. As a result there is considerable confusion at the mines and the output in the various Ohio fields has not been as large as might have been the case. Prices are strong and an advance to the usual winter level has been announced by a number of the dealers. Prices prevailing in Ohio are as follows:

Domestic lump in the Hocking Valley	$1.50
Domestic lump in Pomeroy Bend district	$1.65@1.75
Three-quarter inch	1.35
Nut	1.15
Mine-run in the Hocking Valley	1.10@1.15
Mine-run in eastern Ohio	1.00@1.10
Nut, pea and slack	0.70@0.85
Coarse slack	0.65@0.75

Cincinnati, Ohio

Extremely cold weather has given this market the stiffest conditions that have been in evidence here for many months; this applies to practically all sizes and grades. Almost anything that can be classed as lump, or nut and slack, will bring a good price, and in almost every case at a considerable advance over what was possible even three weeks ago. Nut and slack is selling at $1 at the mines for the grade that sold a few weeks ago for 80c., and then was piled up at the mines and on cars in the railroad yards for lack of demand.

The weather has been the coldest recorded here this year, and possibly for 10 years.

The demand for nut and slack is even more pressing than for lump coal. The factories are adding their requisitions to the already unusual demand from steam-heating plants. There is hardly a pound of free coal of that character and at least one concern is delivering mine-run to fill its contracts which call for nut and slack, but which is not to be had except the company buy it on the open market.

The river coal men together appropriated a fund of $2500 with which to keep steamers moving in the Ohio River to prevent the freezing of the harbor and its approaches. There is an immense quantity of coal in barges in the harbor together with about 100 empty barges, which might result in serious loss should an ice jam, such as is threatened, form. The river coal is important to the Cincinnati trade, as it is a large element in fixing the price of domestic fuel in the immediate retail market here.

Thurmond, W. Va.

The cold wave and the probability of a more or less prolonged cessation of work in the anthracite and some of the bituminous fields have all combined to make the New River operators feel more cheerful over the coming prospects.

There has already resulted a rise in screened coal prices, and a steadiness in tidewater, the latter helped by the likelihood of a strike in the entire British coal fields, involving over one million men. It is probable that this strike would result in the loss to the British coals of a considerable amount of export business, more especially in Italy and South America, much of which should go to the high-grade coals of West Virginia. As it is, two or three of the sales agencies in this

field have already made large contracts for export coals, deliveries on which are badly hampered by the extremely high steamship rates now prevailing.

The Chesapeake & Ohio Ry. is making determined efforts to get a large tonnage from that portion of the New River field now served by the Virginian Ry. along the Winding Gulf; the total shipments from the New River field over the Chesapeake & Ohio showing a falling off of 12% in 1911, as compared with 1910. Loading of coal in this field has been fairly good since Jan. 1, notwithstanding the cold weather and heavy snow. Great difficulty, however, has been experienced in getting coal moved, especially to the West, mainly owing to the number of locomotives put out of the service by the unusually low temperatures.

Charleston, W. Va.

The cold weather has cut down the output in the state and sent up the price of coal except that held down by contract. It has been many years since a cold spell has lasted as long as the present one. The heavy snows and extreme cold, ranging from 5 to 25 deg. below zero, have not only prevented the handling of cars but has otherwise interfered with the mining of coal. Lump and egg has taken a jump, also run-of-mine. Kanawha lump is bringing from $150 to $1.70 at the mine, with run-of-mine at about 95c. New River run-of-mine ranges from $1.20 to $1.45, and New River egg at from $1.60 to $1.70. Indications just before the first of the year were that the output for January would exceed that of last year, but the extreme cold may be the means of cutting it down below a year ago. The jump in prices, however, has been the one really satisfactory movement in the situation during the past 10 days; continued cold weather will probably cause a still further advance.

Louisville, Ky.

Activity such as had not been seen in many years was evident in the local market during the past week, due to the unprecedented cold spell. That which was true of the Louisville market was true of practically every city and town in Kentucky.

While the dealers were busy day and night in filling orders, the charity stations and the relief desk at the office of the mayor were also overwhelmed with applications. For the first time in many years few questions were asked when an applicant who even looked the part made his or her appearance. So widespread was the suffering that few of the poor were able to provide from their own incomes sufficient fuel to supply their wants.

The average prices which prevailed were as follows: Pittsburg, $3.75; Jellico, $3.60; Winifrede, $3.60; Taylor, $3.25. Pocahontas smokeless brought $4.75, and New River Smokeless, $4.50. Kentucky lump continued to sell as low as $3 for a 2000-lb. ton, and Banner lump, $3.25. Straight Creek lump brought $3.75; nut and slack, $2.25, and Gem selling at $3.

A shortage in steam coal which promises to be serious, is also causing much concern. The manufacturers here have been warned that the inactivity at the mines around the Christmas holidays, and the delay in shipments following the heavy snow fall, are elements to be considered. The local dealers have been forced to rely upon their reserve supplies for coal for manufacturing purposes. How long they will be able to meet the demands from this source seems to be questionable.

Memphis, Tenn.

Memphis is in the middle of the best coal selling weather that we have experienced for 12 years. We are having severe weather with the temperature low and a strong wind blowing from the north, laden with snow and sleet. The retail yards in Memphis have drawn heavily on their stocks and the smaller dealers have practically exhausted what they had in storage.

While there has been no advance in price, it has given the mines about all they wanted at prevailing prices, which are as follows:

Kentucky No. 1 lump	$1.50
Kentucky No. 2 lump	1.25
Kentucky No. 1 nut	1.10
Alabama No. 1 lump	2.00@2.50
Jellico lump	2.00@2.25
Jellico block	2.25@2.50
Round coal	1.65@1.90
Cahaba coals	2.50@3.00

These maximum prices are being secured in isolated places. Screenings are scarce, and it is impossible to secure sufficient to take care of the steam business for this section.

Nashville, Tenn.

Nashville and vicinity are in the midst of the blizzard which is taking in the entire country, and just as was predicted several weeks ago, the unprecedented cold spell has caught all the dealers short of coal.

The usual trouble around the mines with freezing weather and snow, retarded considerably the loading of coal. This together with the shortage of cars on the one week when every mine in the field could have run, full capacity, added much to the demoralized condition.

There is still a big demand for screenings at the top market price. Outside of this there has been no relative change in this field over recent quotations. Some few people, as an extra inducement to have a little spot coal shipped immediately, have seen fit to offer a slight advance on the regular prices, but this condition has not prevailed to any extent.

Indianapolis

Continued cold weather has caused all coal mines in the state to work full time, with large forces, to supply the demand. Previously, the mines had been worked on an average of about half time. Many Indiana cities, depending on natural gas for fuel, have sent rush orders for coal, the gas supply being insufficient.

The indications are that the demand will continue, since big consumers have begun to store in anticipation of the miners' strike after Apr. 1. The operators are, however, somewhat pessimistic, believing the cold weather will not last and that the strength of the market will vanish. It is too late for retail dealers to stock up heavily since they have been turning their surplus into cash.

Chicago

Wholesale prices in the Chicago coal market are on a higher average level than they have been in the last six years. Severely cold weather, with the mercury below the zero mark most of the time, gave a sky rocket turn to the price situation that caused a stir in every direction.

On steam coals the rise has been far more rapid than on those of the domestic variety. Smokeless mine-run has risen from 80c. to $1.10 on shipments direct from the mines, with a strong tendency toward another jump to $1.15. Lump and egg sell wholesale at $2.15 to $2.25. Splint coal, which sold a short time ago for $1.10 to $1.25, moves freely at $1.55 to $1.60. Low grade screenings have risen almost 100% and a boost of 50% in other sizes has not been unusual.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62
Egg	2.62
Steam lump	2.25
Screenings	1.87
Springfield:	
Domestic lump	$2.57
Steam lump	2.32
Mine-run	2.27
Screenings	1.82
Clinton:	
Domestic lump	$2.52
Steam lump	2.25
Mine-run	2.15
Screenings	1.77
Pocahontas and New River:	
Mine-run	$3.15@3.30
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville, and Wise County, $4.50@4.65; byproduct, egg and stove, $4.85; byproduct, nut, $4.55@4.65; gas house, $4.85.

Minneapolis—St. Paul

The local coal market has shown great activity during the past week. The weather has continued cold, stocks have been diminishing at a rapid rate and some dealers are looking for a coal famine. This is not probable, however, as a

day or two of milder weather would allow the railroads to bring in hundreds of cars of coal which is now stalled on side-tracks on all the roads.

This stretch of 20 deg. below zero weather has played havoc with the railroad service. The Great Northern reported Friday that they had 1400 loaded cars of coal at their yards in Duluth, but were unable to move them. A frozen car, they claim, pulls twice as hard as under normal conditions, and a frozen engine uses up one-half its energy in moving its own weight. Retailers' stocks are low on all grades of coal, but especially on anthracite. A canvass along the H. & D. division, which supplies the large resident district of Minneapolis, shows there is a shortage on all grades of anthracite, and only one car of stove size was found at any of the twelve yards.

St. Louis, Mo.

The coal market in St. Louis is in an extraordinary condition, which has obtained since the middle of last week, when the weather went down to 10° below zero and was followed by snow. The snow held up the railroads and ice blocked the ferries on the river to such an extent that the yards in East St. Louis were congested and it was impossible to get coal across.

Carterville coal is worth in the neighborhood of $1.50 for the larger sizes, and there is an unlimited market for the smaller sizes at almost any price the shipper demands. This same condition applies to the Franklin County coal, but this product is moving almost exclusively into the Northwest.

The local demand for anthracite has been exceedingly good, but shipments are hard to get. The same condition applies to smokeless lump and egg; gas-house and byproduct coke are in good demand, but it is almost impossible to get shipments. There is no coal coming in from the Saline or Springfield districts, as these coals are in demand in the Northern market, where they are bringing a better figure than St. Louis could stand. A small tonnage of Arkansas anthracite is moving in, but not enough to relieve the market any.

Portland, Ore.

Portland had a touch of real winter weather during the week. It was in the nature of a silver thaw, which means that telegraph and telephone wires, trees and fences became coated with ice to a thickness of an inch or more and with disastrous results because of the crushing weight.

The coal and fuel dealers in general were buried under orders that poured in at an amazing rate and which were difficult to fill promptly. One fuel dealer stated that business increased about 300% during the first days of the cold snap.

Train service was tied up in eastern Oregon during the storm, but not sufficiently to cause any disturbance.

Spokane, Wash.

Coal has been in a great demand in the territory known as the Inland Empire during the last week, but the prices have remained stable. The cold weather is drawing upon the stocks to a considerable extent, but the mines are furnishing their share, and the demand is easily met. Indications are that the cold weather will continue for a few more days, and in the meantime the coal dealers are doing their best. Prices are as follows:

Kind	Wholesale	Retail
Rock Springs	$7.20	$9.00
Owl Creek	7.20	9.00
Kirby	7.20	9.00
Carney	6.70	8.50
Bearcreek	6.35	8.25
Roslyn steam	5.25	6.25
Canadian steam	5.25	6.25

Foreign Markets

Great Britain

The tonnage position is satisfactory, and there is a good tone to the market. Prices, however, are about unaltered and are as follows:

Best Welsh steam coal	$4.14@4.20
Seconds	4.02@4.08
Thirds	3.78
Best dry coals	4.02
Best Monmouthshire	3.78
Seconds	3.60
Best Cardiff small coals	2.16
Seconds	1.92

The above prices for Cardiff coals are all f.o.b., Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days less 2½ per cent.

Production and Transportation Statistics

Norfolk & Western Ry.

Statement of commercial and company coal from mines on the Norfolk & Western Ry. for the month of December, 1911, is as follows in net tons:

From	Commercial	Company
Pocahontas field	1,112,126	97,748
Tug River field	147,107	44,100
Thacker field	167,232	63,831
Kenova field	68,885	9,357
Clinch Valley field	91,032	7,194
Total	1,586,382	222,230

The following are shipments from the different fields in West Virginia:

	Transfer Coal	Tipple Coal	Total Coal
Pocahontas	1,142,793	22,358	1,165,151
Tug River	188,506	2,701	191,207
Thacker	226,431	4,632	231,063
Kenova	70,586	7,656	78,242
Total	1,628,316	37,347	1,665,663

Total coke shipments, originating entirely in the Pocahontas field, were 96,609 tons.

The Car Situation

On Jan. 3 there were 135,938 more cars on the lines of the members of the American Railway Association than the demand called for. This was a big increase from the statement of the previous fortnight, when the surplus amounted to 76,814. That in turn compared with a surplus of 36,143 as of Dec. 6. Most of the increase in the latest report resulted from a falling off in the movement of coal.

In the two weeks ended Jan. 3 the surplus of coal cars increased from 35,409 to 64,719, and the surplus of box cars increased from 23,485 to 36,145. Miscellaneous and flat-car surpluses followed the general trend with considerable increases.

On the corresponding day last year the net surplus of idle cars was 106,924. Two years ago it was only 38,416; in 1909, 332,513, and in 1908, 341,100.

Financial Notes

The Northern Securities Co. reports the earnings of the Crow's Nest Coal Co. for the year ending Dec. 31, 1911, at $27,552. Earnings were curtailed because of the strike.

Monongahela River Coal & Coke Co. has declared a dividend of $2 a share on the preferred stock out of earnings for fiscal year ended Oct. 31; payable Jan. 25 to stock of record Jan. 22.

Consolidation Coal Co. has declared the regular quarterly dividend of 1½% on the capital stock and a dividend of 1½% on the subscription receipts for stock carrying dividends declared after Jan. 31, 1911, both payable Jan. 31 to stock of record Jan. 26.

Virginian Ry. proposes to increase its stock from $36,000,000 to $65,000,000 through issuance of $29,000,000, 5% cumulative preferred. Matter comes before stockholders at annual meeting here Jan. 27, but Rogers estate is believed to own all the road's common stock save $500,000. Belief is that extension to the Great Lakes through acquisition of other railroads or through building is contemplated.

The board of directors of the Lehigh Valley R.R. Co. has authorized the distribution of $6,060,800, or 10% on the total outstanding stock, payable Feb. 26, 1912. Coincident with this the Lehigh Valley Coal Co. has authorized the organization of the Lehigh Valley Coal Sales Co., with a capital stock of $10,000,000, consisting of 200,000 shares of the par value of $50 each, of which 121,216 shares of the par value of $6,060,800 will be immediately issued. The readjustment is made necessary by the decision of the supreme court rendered in May, 1909, by which it was held that a railroad company cannot lawfully transport coal owned by it.

The preferred and common stock of the New River Co., owned largely by Boston and Pennsylvania people, has just been listed on the Boston Curb Exchange. The bonds of this company are already listed on the Boston Stock Exchange. This stock was widely distributed in 1906 through a number of local interests and the company sells much of its product through Maine, Massachusetts and Rhode Island. The preferred stock paid dividends through 1907 and 1908, but has not paid since then. The listing on the Boston Curb has been at the application of large shareholding interests who desire to see a broad, natural market in the stock.

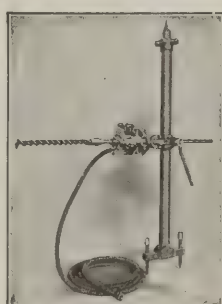
Howells Drills Effect Economy Of Power And Maintenance



No. 2
Compressed Air Drill

We Bore The World's Coal

Drill illustrated has a reciprocating high speed motor mounted on column or post. All parts are made to resist the hardest kind of abuse in unskilled hands. Will drill seven feet per minute into coal with 60 lbs. air pressure.

This is only one of over 50 different types for every service.

Catalog No. 28 shows them all. Send for it.

The annual meeting of the stockholders of the Hill Publishing Company, for the election of directors for the ensuing year and for the transaction of such other business as may properly come before the meeting, will be held at the office of the company, in the Hallenbeck building, 497-505 Pearl Street, Borough of Manhattan, New York City, N. Y., on Tuesday, January 30, 1912, at 12 o'clock noon. Dated, New York City, December 19, 1911. ROBERT McKEAN, Secretary.

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—An experienced mine electrician who can wind armatures and keep in thorough repair, a half dozen direct current generators, a dozen locomotives, and several motors located at different mines; location a plain mining camp, on short branch in central West Virginia. Wanted, by same company, a superintendent-foreman for small mine having an output of 400 tons per day, man who can survey preferred; state age, experience fully, where obtained, in what positions, education and where obtained, married or single, teetotaler or otherwise, and salary expected. Address Box 7, Coal Age. Feb. 3.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—Contract work (mine, mill, etc.), or assistant, by married physician; one year hospital experience; also private practice in Pennsylvania. Address Box 5, care Coal Age. Jan. 27.

whether you generate your own electric power or buy it from a central station, we can furnish the motor-generator set to do your electric locomotive work.

If you want lower mining costs

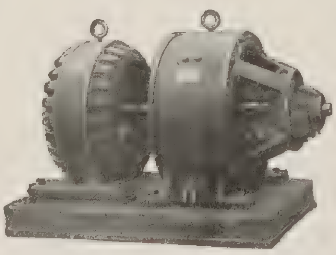
you can have them by using a Baldwin-Westinghouse Mine Locomotive in place of mules.

Let us help you reduce

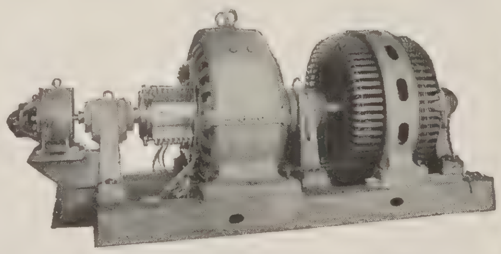
the time and trouble it now means to get out your coal. We have the figures to show that Baldwin-Westinghouse Mine Locomotives are the most efficient, reliable and strongest electric haulage engines on the market.

Expense

of installation can be more than made up in the first year or two's operation.



Motor-Generator Set
for Mines with one locomotive



Synchronous Motor-Generator Set
for Mines with several locomotives

Either company will give you full particulars

COAL AGE

Vol. 1 NEW YORK, JANUARY 27, 1912 No. 16

THE decision of the U. S. Supreme Court, approving the Employers' Liability Law, marks an epoch in labor legislation. Its sole interest and importance to coal men is in the shadow it casts before. No recent act so clearly betokens the trend of thought pertaining to our social problems, as does this ruling of our highest national court.

True! this law was designed principally to deal with our great railroads, and affects interstate labor only; however, to quote the Supreme Court decision: "The laws of the States, in so far as they cover the same field, are superseded, for necessarily that which is not supreme must yield to that which is."

Legislators in every state now have a definite and accepted ruling laid before them. Therefore, with this decision to guide them, is it not likely that lawmakers will create measures in behalf of intrastate labor, exactly paralleling the approved Federal Act governing interstate employment unless indeed those vitally interested show due concern for the passage of more equitable legislation?

The law as approved by our highest tribunal makes employers of interstate labor liable for accidents to employees whether the mishap is due to negligence on the part of the victim, or is caused by a coemployee. Such a liability law enacted and enforced in a coal state, would mean bankruptcy to three out of every four companies, should a disastrous explosion or fire occur at any one of their mines. Under such a liability law, there would be no reasonable limit to the burden which could be assessed by a jury on the defendant

Coal operators can no longer afford to evade the issue. The problem of a proper accident provision for industrial workers cannot be ignored. The question is, Can we not secure fair and uniform compensation laws that will provide for a miner and his family in case of accident or death, and yet permit the stricken company to recover and continue in business?

The blackest stain on the coal industry has come from the deceit and perjuries accompanying accident investigations. It is nearly always the same old story—a coroner's jury composed of farmers, doctors or some other class of men who never saw the inside of a coal mine, and then the usual verdict, "caused by a blown-out shot." This deplorable condition is an outgrowth of unjust laws. The operator chooses the only course that will avoid financial disaster, and strives by fair or foul to avoid conviction.

That present laws are ineffective is proved by the reports from employers' liabilities companies, which show that of all the accidents reported to them, only one in eight led to a settlement. Under the law's technicalities, any effort on the part of the coal company to settle, is sure to be presented to a jury as evidence of guilt Last but not least, the relations of operator and miner under the present act are constantly embittered, and this lack of harmony is not calculated to restrict the number of accidents.

The United States is practically the only country that retains the principle of an employers' liability law. Other nations have adopted some form of compensation act, based on the idea that injuries to men, like accidents to machinery and buildings, should be imposed on the employer. One is as much an expense of production as the other.

When this principle is adopted, the mining company can shift the risks of compensation to an insurance company, which, for a reasonable premium, will carry this hazard for them. The insurance company, to operate with success, would have to vary its premium on each mine in accordance with a fixed standard of safety. The charges to operators of mines having many natural dangers would be greater than to companies operating in comparatively safe seams.

In this way, a just tax would be placed on each coal company; present uncertainties would be removed through the operator's knowing beforehand what definite compensation charge he must add to his cost of mining; insurance companies could form a more precise idea of the charges they might be compelled to pay, and thus place their business on a scientific basis; and lastly, the injured workman and his family would receive all the compensation paid over by the employer and the insurance company, instead of having 47 per cent. of the money go to enrich a class of lawyers properly dubbed "ambulance chasers." In a later issue, we will discuss the plan of voluntary compensation as adopted by the H. C. Frick Coke Company.

European Wash House Practice

Special Correspondence

The first of a series of articles to be published on this subject. The question is discussed here along general lines, while the succeeding papers will deal with the problem in greater detail.

It has long been a recognized fact that the occupation of mining, both in metalliferous and coal mines, must be ranked as one of the callings involving a considerable amount of physical discomfort and uncleanliness. And further, there is no doubt that in the past a great proportion of the sickness and loss of time among operatives is traceable to the fact that the miners on leaving work were not provided with adequate means for bathing and washing. No suitable arrangements were provided whereby they could change their wet and dirty clothes for garments more suitable for exposure to the outside air.

Many of these miners have to travel considerable distances to their homes and in the case of married men, the size of the house and the presence of other inhabitants interferes with the bathing arrangements, with the result that the percentage of mortality must have been materially increased. Cases of phthisis and similar complaints are at the present day far too common, and although mining companies are frequently most generous in the provision of medical attendance, it is obvious that the root of the trouble lies deeper and that the true remedy of the problem is in preventive, rather than curative means.

For this reason, in Europe, and especially in France, Germany and Belgium, the question of providing adequate washing, bathing and clothes drying appliances is receiving considerable attention and some remarkable installations have been made to which attention may here be drawn.

Referring to the types of appliances available for such purposes, one may first of all consider the question of proper change of apparel. The miner, on coming up from the warm and usually damp workings of the mine, finds, unless he is properly protected, a blast of cold bleak air meeting him, often accompanied with rain or snow, and these conditions are aggravated by the fact that he has either to walk or ride some distance before he reaches his home. For this reason some form of dressing accommodation is urgently necessary.

Clothes Suspension Method

Two types of such plant exist in Europe. The first of these consists of a large hall with benches on which the workmen sit while changing clothes, the hall being given considerable elevation and suitably warmed. In the upper part of the hall is suspended a rack arrangement furnished with a number of pulleys corresponding to the total number of employees in the mine. Over these pulleys work metallic cords carrying at one end a hook or other form of gripping appliance to which the wet garments can be attached. At the other end is a counter weight and locking device whereby the clothes can be hauled up into the roof and locked in position, the key of the lock being retained in the possession of the workman owning the clothes.

Fig. 1. Dressing Room and Clothes Hoist at the Poirier Mines

A current of warm air circulating through the building, dries the clothes and thoroughly aerates them, removing contaminating influences; the pulleys are spaced a sufficient distance apart to provide free room round each set of clothes for the circulation of air. The workman, on coming to work, after passing the time

check office, comes into the dressing hall, brings down his dry working clothes, changes, hangs on the hook his ordinary garments and hauls them up locking them in their position in the roof.

On return from the mine, he enters the dressing hall, often by means of a covered way from the pit mouth, so as to prevent the access of cold air to the heated body. After washing in the appliances to be described shortly, he brings down his dry clothes, changes, hangs up the wet mine clothing, which will then be dry and ready for the next time he comes to work. In some establishments this arrangement is supplemented by a clothes-washing and drying plant whereby at suitable intervals the dirty mine clothes are washed and dried rendering them fit for further use. This type of plant is in extensive use particularly in Germany and Belgium.

Closets and Lockers

An alternative to this equipment which is to be found in some mines, is to use clothes chests or lockers. These are generally made of light steelwork frames, cased in with expanded metal, so as to permit at all times a free supply of air to circulate through the clothes. They are usually ranged round the sides of the dressing hall and each locker is furnished with a lock and key, the latter being in possession of the workman.

The usual dimensions of these lockers is 1.75 m. in height, 0.3 m. in depth, the same in width, and they are usually elevated from the floor by means of struts to a height of about 0.15 m. to 0.3 m. Sometimes they are divided into two compartments, the top one being reserved for hats, coats, etc., while the lower one is used for underwear and boots.

The dressing room and clothes hoists in use at the Marcinelle-Nord Colliery in Friesland belonging to the Fiestaux Pit of that company is shown on the front cover of this issue. It will be seen that the apartment is well lighted and warmed and that in all its arrangements it is capable of rapid and easy cleaning. The illustration Fig. 2 shows a section of the type of expanded metal lockers used in the alternative arrangement for this purpose. The possibility of adequate supervision and of proper hygiene is apparent. In Fig. 1 is shown a similar installation to that on the front cover, being a dressing room and clothes hoist at the St. Charles pit of the Poirier mines, installed by Goehmann & Co., of Brussels. This firm has installed about 80% of the dressing and bathing installations existing in Belgium, France, Germany, Russia, Spain and Austria in connection with mining equipments.

Bathing Arrangements

An equally important and perhaps even more important branch of the subject is the question of baths and wash-houses. The average miner's home is not well equipped for the complete bathing necessary after the arduous toil to which the operator is subjected, and the methods adopted on the Continent are therefore of interest in this connection.

A considerable amount of thought is of course necessary in order to provide adequate accommodation for a large number of men at one time without running up the expense of the installation to an unreasonable figure, and therefore simplicity combined with efficiency is the keynote for such work. At the same time, it is astonishing to what a degree of comfort it has been found possible to bring the bathing accommodation both for men and women employed in the collieries of Europe. Hot and cold water is usually available, and in some cases, especially for the engineers and senior officials employed in the mine, full baths are provided. Where these are not available, however, shower baths are used and washing operations can be conducted in privacy by means of brickwork cells closed with curtains or screens.

Through the courtesy of Messrs. Goehmann & Co., we are able to show several illustrations of such equipments. In Fig. 4 for example, is a view of the exterior of the building devoted to the spray baths and dressing room at pit No. 17 of the Monceau-Fontaine Colliery in Belgium. The interior fittings of such installations may be judged by Figs. 5 and 6 showing respectively the spray baths and lockers at the Fiestaux pit, and the spray baths for the miners at the St. Charles pit of the Marcinelle-Nord and Porier collieries.

The cells are usually constructed in glazed white tiles which are of great hygenic advantage, do not discolor, resist the influence of weather and frost, and are simple and practical to use. They are plastered on to the structural work by means of cement mortar, and in order to give the free standing walls a special resisting power, a lining of bands of iron running horizontally are usually placed in each layer or in every third or fourth layer. If shaped tiles are used at the ends of the walls, the ends are propped up with vertical iron bars or gas piping bedded into the ground at their lower end. The crevices of the walls are filled in with white marble, cement or cement mortar.

Fig. 3. Wash House with Basins

Comparison of Method

An alternative method is to use enamelled brick and in order to show the relative extent to which the various methods enumerated above are adopted, Table 1, is attached giving a few of the principal collieries which have adopted dressing rooms and wash-houses.

The first column gives the number of workers provided for in the clothes hanging appartus in the roof of the dressing

halls and the second gives the number of workers for which lockers are provided. The third column gives the shower baths built of enamelled brick, and the fourth the shower baths built of tile in the manner above described.

The illustration Fig. 7 shows an alternative method of securing privacy in the various shower bath cells by the use of enamelled sheet doors. Where expense is cut down to the finest point, wash basins provided with hot and cold water are used, as shown in the illustration Fig. 3. For heating the water four steam and two hot water boilers are used.

As a general rule the dressing hall and washing equipment are complementary to one another and are contained in the same building, inasmuch as one operation without the other is hardly satisfactory. As a typical example of the way in which such installations are arranged may be taken the equipment provided at St. Etienne mines of the Loire.

Equipment at the St. Etienne Mines

Four doorways are provided into the building, two leading to the subsidiary departments such as the store and lamp room, and two opening directly on to the dressing hall. The main hall has dressing accomodation for 500 workers. The miners in changing clothes divest themselves as completely as possible of their working outfit and then proceed to the shower baths immediately adjacent to the hall. The officials of the mine change and bathe in separate compartments, clothes lockers being provided for them. Urinals and water closets are provided, as are also the necessary boilers and apparatus for the heating system of the building and the hot water required for the baths.

At the other end of the building are subsidiary offices including naphtha stores, the lamp filling room, the lamp cleaning department, stores, and the lamp repairing room. In this way the miner is able to obtain and return his lamp in the same building as is provided for his dressing and washing accommo-

Fig. 4. Exterior of the Monceau-Fontaine Bath House

Fig. 5. Spray Baths at the Marcinelle-Nord Colliery

dation. Immediately over the lamp departments is another story, in which are two rooms devoted to the engineers' baths and dressing accommodation. In order to provide a free circulation of air extensive ventilation is provided on the Louvre system in the roof of the building, and in addition there are ventilating windows in the side of the structure.

In an article of this description it would be impossible to give a complete idea of the way in which bathing and dressing accommodation have been adopted on the Continent. It may, however, be said that almost without exception the facilities provided have been greatly appreciated by the workers who have availed themselves to a large extent of the equipment provided.

Whether such installations should be made compulsory and the use of them by the miners should be part of the obligatory routine of the mine is a matter of opinion. There is, however, no doubt that the provision of such accommodation in connection with collieries and mines is a step in the right direction, not only from the point of view of the worker, but also that of the employer, inasmuch as it leads not only to an increase of contentment with the conditions of employment on the part of the worker, but has a reflex action on the general health and efficiency of the operators. This has been found by experience to be a great asset to the working of such mines as have adopted the systems above described.

Mine Cave Commission

Special Correspondence

The mine-cave commissioners who were recently appointed by Governor John K. Tener, of Pennsylvania, have made some progress in their investigation into mine subsidences in the anthracite region, and the damage resulting therefrom.

Recently the commissioners requested the director of the department of public works in the city of Scranton to inform them of the number of cubic yards of ashes and rubbish collected in Scranton during the year 1911. The bureau of engineering of the department of public works estimates that 108,016 cu.yd. of any given material will fill a 5-ft. bed extending over 13½ acres. That quantity of ashes and rubbish was collected and wasted during 1911 in Scranton.

These ashes will serve for the upper beds, but as the lower beds are much thicker than the upper a large amount of rubbish will be needed to replace them. Though this be conceded, it has been pointed out that most of the damage that results from mine caves is directly attributable to the subsidences in the beds near the surface.

List of Commissioners

The following is a list of the commissioners: W. J. Richards, president, Pottsville; W. L. Connell, Scranton; E. J. Lynett, Scranton; W. A. Lathrop, Wilkes-Barre; George W. Davis, secretary, Lansford; Charles Enzian, Wilkes-Barre; W. L. Lewis, Pottsville; J. Benjamin Dimmick, Scranton; Reese A. Phillips, Scranton; Charles Stevens, clerk, Scranton.

The commission has decided to investigate the leases to ascertain what provisions are embodied in them in reference to surface rights. In some leases already examined by the commissioners, entire tracts of land are protected to the extent that, in the event of a mine cave, the property damaged must be placed in the same condition as it was previous to the disaster brought about by the cave that affected it.

It is the intention of the commissioners to do their work thoroughly. They regard the situation as serious, but not irremediable. Within a few hours of the commission convening, the children in school No. 23 of this city had to be dismissed; while on a previous occasion, when the mine commission was assembled here, a house in Ross Ave. was engulfed from roof to cellar.

Pathogenic Mine Atmospheres—III

By Edwin M. Chance*

Here are discussed the active pathogenic gases, as carbon monoxide, nitrogen peroxide, hydrogen sulphide and sulphur dioxide. The possibility of a skin inhalation of carbon monoxide is considered.

The presence of carbon monoxide in mine air may be traced to several sources. As it is a product of the incomplete combustion of carbonaceous substances, it is formed by explosions of coal dust or firedamp, by underground fires, and by the detonation of most explosives. It is well known that carbon monoxide is produced when air at ordinary temperature acts upon bituminous coal. It has remained, however, for Mahler and Denet to prove the presence of this gas in mine air from such a source. These writers have found as much as 0.004 per cent. of carbon monoxide in the air of well ventilated mines. The statement may be found in the literature that this gas is also produced by the decomposition of organic matter other than coal in the mine. As the presence of carbon monoxide has been considered indicative of mine fires, its presence from other causes must be given due weight before forming a definite opinion as to the existence of a fire.

Its principal claim on our attention, however, lies in its physiological action. As this gas is odorless and nonirritant, it may be breathed in considerable quantity without the subject being aware of the fact, the first warning being given by grave functional derangement. Briefly, the mechanics of its action may be thus described: Carbon monoxide, having an affinity for hemoglobin about 200 times greater than that of oxygen, readily replaces the latter in the blood when breathed. As the blood becomes saturated with carbon monoxide its oxygen capacity becomes correspondingly diminished, until it can no longer supply sufficient oxygen to fulfill the requirements of the organism. In addition to this, the gas is said to cause degeneration of the cells of the organism, and thus serious nervous disorders are brought about. Haldane and Douglass state that physical disablement is produced in man when about 50 per cent. of the blood is saturated with carbon monoxide, death occurring when this figure increases to 80 per cent.

Effect of Carbon Monoxide

Owing to its great affinity for carbon monoxide, the blood may become saturated to a dangerous extent when this gas is present even in minute quantities. It is difficult to give fixed points at which an atmosphere containing carbon monoxide will produce given effects. It has been stated, however, that quantities under 0.02 per cent. have no appreciable action on man, while the lethal percentage has been fixed at 0.5 per cent. Herman has tabulated the action of carbon monoxide as follows:

THE ACTION OF CARBON MONOXIDE

Percentage in air	Effects on man
0.05	After half an hour or more, giddiness on exertion.
0.1	After half an hour or more, inability to walk.
0.2	After half an hour or more, loss of consciousness and perhaps final death.
1.0	After a few minutes, loss of consciousness and final death.

When any given percentage of carbon monoxide is breathed, the blood tends to reach a degree of saturation at which the carbon monoxide and oxygen in the air are in equilibrium with the carbon monoxide in the blood. If we apply the law of mass action to this phenomenon, it will be readily seen that a change in the proportion of oxygen present will have an effect upon the system, carbon monoxide-oxygen-carbon monoxide hemoglobin, opposite in direction to that produced by a change in the proportion of the carbon monoxide. Now the data on which the statements as to its toxicity have been based have all been gathered when carbon monoxide was breathed mixed with air containing 21 per cent. of oxygen. Unfortunately, however, when carbon monoxide is met with in dangerous quantities in the mines, the oxygen percentage is, as a rule, far below the normal. It seems to the writer, therefore, that under such conditions far lower proportions of carbon monoxide than those noted would produce serious results. It is regrettable that we have but little real data bearing on this point. A case has been reported, however, in which several men lost their lives on entering an atmosphere containing 0.0023 per cent. of carbon monoxide and 4.874 per cent. of carbon dioxide. The oxygen percentage was not stated. As has been mentioned before, when considering the toxicity of an atmosphere, the action of no one of its constituents can be taken alone, but all must be considered together.

Animal Test for Carbon Monoxide

As carbon monoxide is poisonous to warm-blooded animals generally, its effect upon birds and mice has been taken advantage of to give warning of its presence. Haldane, who has been instrumental in bringing this test to the notice of mining engineers, uses these words in describing it:

"The principle of the test is as follows: In small warm-blooded animals the rate at which chemical changes occur in a given body weight is enormously greater than in large animals. Thus a mouse weighing about half an ounce consumes about fifteen times as much oxygen as half an ounce of the human body would consume in the same time. A reason for this difference is evident enough with bodies of the same shape and composition, but of different sizes; the surface increases as the square of any corresponding diameter, but the mass as the cube. The bigger an animal is, therefore, the less surface will it have for a given mass, and the less rapidly will a given mass of it lose heat to the environment; or the less heat, and consequently the less oxygen, will a given mass of it require in order to maintain the normal body temperature. Not only are the chemical changes in the small animal far more rapid, but the rate of respiration, circulation, etc., are correspondingly increased. It is difficult to count by the eye the rate of breathing in a mouse, and quite impossible to count its pulse rate. By a photographic method of recording the electrical changes which accompany the heart beat, Miss F. Buchanan, of Oxford, has recently shown that the pulse rate in mice and small birds is from 700 to 1000 per minute.

"It follows that the small animal will absorb any poisonous gas far more quickly than a man will, and will, therefore, show symptoms of poisoning far sooner. It can, in fact, be employed to show what will ultimately happen to a man if he remains in the poisonous air. This, and this alone, is the principle of the test. The small animal is not, in the long run, more sensitive than a man to a given percentage of carbon monoxide; indeed, the opposite is almost certainly the case."

Symptoms of Monoxide Poisoning

The symptoms of poisoning by this gas are varied. When small quantities are breathed there may be drumming in the ears, with more or less frontal headache and nausea. As the poisoning proceeds, giddiness and lassitude will set in, followed by progressive loss of power in the lower extremities, merging into paralysis, which eventually invades

*Chief chemist, Philadelphia & Reading Coal & Iron Co., Pottsville, Penn.

Note—Abstracted reprint from Journal of Franklin Institute, November, 1911.

the rest of the body. Synchronously with loss of muscular power the mental processes become deranged. Should the subject, however, inhale an atmosphere containing much carbon monoxide, almost instant insensibility will be the result. After recovery from exposure to this gas, severe pains in the head and extremities have been frequently noted; though a more serious after-effect is pneumonia.

The post-mortem appearances are characteristic. As carbon monoxide hemoglobin possesses a deep violet to cherry-red color, the face and lips have a remarkably fresh and lifelike appearance, very different from the bluish or livid pallor produced by a deficiency in oxygen.

Effect of Nitrogen Derivatives

Nitrogen peroxide is one of the products of the combustion of certain explosives. It is extremely poisonous when breathed. Peterson and Haines state: "Habitually breathed in small quantities and great dilution, it produces severe chronic diseases. In acute poisoning, immediate dyspnea, tightness of chest, coughing, fainting, cyanosis, diarrhœa and collapse. Death within 40 hours, though symptoms of slight poisoning are delayed, in which case the first symptoms are headache, desire for fresh air, thirst, and then suddenly symptoms of aggravated character—distress of breathing, anxiety depicted on face, cold perspiration, protruding eyeballs, and spasmodic coughing, followed by vomiting."

Effect of Sulphur Compounds

The presence of hydrogen sulphide in mine air may be brought about by the bacterial decomposition of organic matter, by the heating of coal by a mine fire, or by the action of organic matter on sulphates in solution. It is slightly heavier than air and possesses a strong odor, 0.01 per cent. being readily detected by the olfactory organ. This gas is even more toxic than carbon monoxide; it is stated that as little as 0.02 per cent. may have a toxic effect. Birds are especially sensitive to it, being killed by 0.05 per cent. "Breathed in its pure state, this gas is immediately fatal. It acts upon all animals through all tissues, especially the lungs. If somewhat diluted, it produces nausea, giddiness, cold skin, labored breathing, irregular action of the heart, pains in the stomach, and death by coma or in violent convulsions, with tetanus and even delirium. In greater dilution sleepiness will be produced, the continued respiration of the gas proving fatal, sensibility not being restored. In exceedingly dilute condition it sometimes occasions febrile symptoms somewhat resembling typhoid. Air containing 0.05 per cent. was the limit that men could breathe (Lehmann). Sometimes symptoms appear after a considerable lapse of time after breathing the gas, and they may continue for some days."

COMPARISON OF THE PHYSIOLOGICAL ACTIONS OF AIR CONTAINING VARIOUS POISONS (LEHMANN).

Gas	Quantity causing rapid death	In ½ to 1 hour caused illness and danger to life	No serious effect in ½ to 1 hour	Slight symptoms after several hours
Sulphurous acid.....	....	0.04—0.05%	0.005%	0.002—0.003%
Carbon dioxide......	30%	about 6.0—8.0%	4.0—6.0%	2.0—3.0%
Hydrogen sulphide..	0.1—0.2%	0.05—0.07%	0.02—0.03%	0.01—0.015%
Carbon monoxide....	....	0.2—0.3%	0.05—0.1%	0.02%

The presence of sulphur dioxide is probably one of the surest indications we have of the presence of a mine fire. Fortunately the gas is so suffocating that ample warning is given of its presence. Though notably toxic in its action, workmen exposed to the gas may establish considerable tolerance toward it.

A Suggested Danger in Helmet Work

While a great volume of material has been written on the subject of the requirements of a man equipped with breathing apparatus, it has occurred to the author that a most important phase of the matter has been neglected, namely, the insensible respiration. In addition to the oxygen absorbed through the lungs, the blood is continually being supplied with oxygen through the skin. Gerlach[1] states that the ratio of oxygen supplied by the skin to that supplied by the lungs is as 1 is to 137, while Regnault[2] and Reiset set the ratio at 1 to 180. Should the wearer of a breathing apparatus enter an atmosphere low in oxygen, the inconvenience caused by the curtailment of the supply of this gas through the skin would probably be negligible. Should, however, the atmosphere contain much carbon monoxide, there might be considerable cause for apprehension, when we consider that carbon monoxide has over 200 times greater affinity for hemoglobin than oxygen, and practically the same diffusibility through animal membrane. Of course, this danger would only become pressing after long exposure to such an atmosphere. It is for the foregoing reasons that I cannot too strongly urge those who may have direction of rescue parties to expose their men no longer than necesary to lethal atmospheres.

Colliery Steam Piping Suggestions

By H. H. Lawrence

Steam pipes that are well covered and well drained save money by prevention of accidents and the reduction of waste and repairs.

The installation of a steam power plant in the coal-mining field should call for no less careful consideration and design than in other industrial fields. Unfortunately, however, it often receives but scant attention, with resulting serious loss to the operator.

Some points to be considered in designing a system of steam piping are: (1) That as soon as the steam leaves the boilers it begins to condense, and since condensation cannot be absolutely prevented the design should provide for its removal. (2) Expansion in the steam line should always be provided for. (3) Valves should be located, if possible so as to allow one portion of the steam-piping system to operate while the other may be shut down for repairs. (4) Although there is no perfect heat insulator, the loss of heat from steam pipes by radiation may be reduced to a minimum by the employment of a proper covering.

It has been found experimentally that each square foot of uncovered iron pipe surface will radiate about three British thermal units per hour for each degree Fahrenheit difference between the temperature of the atmosphere and that of the steam. The exact amount of radiation depends on the humidity of the air and somewhat on the velocity with which the steam flows in the pipes. Assuming this figure to be 3 B.t.u. per hour per square foot of radiating surface, the economic loss in any particular case may be calculated from the following formula.

$$L = \frac{3\,A\,(T - T_1)\,H\,V}{965.7 \times 2000 \times E}$$

In which L is the loss in dollars per annum due to steam condensation. A equals area in square feet of the pipe surface exposed to the air. T equals temperature of the steam in degrees Fahrenheit. T_1 equals mean temperature of the surrounding air in degrees Fahrenheit. H equals the total number of hours steam is conveyed through pipes per annum. E

equals the evaporation of water in pounds from and at 212 deg. F. per pound of coal; V equals value of fuel per short ton including handling and disposition of ashes, etc., and 965.7 equals the latent heat of steam at 212 deg. F. If A equals 1000, T equals 315 deg., T_1 equals 60 deg., H equals 3000, E equals 10 and V equals \$3. Then L equals \$356.47. The 1000 sq.ft. of pipe surface is equivalent to 577 lineal ft. of 6-in. pipe or 443 ft. of 8-in. pipe.

By using a proper covering as much as 90 per cent. of this loss may be saved. There are many makes of covering on the market and the best way to secure a good article is to purchase it from a firm having an established requtation. Pipe covering is usually made in two forms; one, known as sectional, which consists of molded segments held in place by metal straps and is easily applied; the other, a plastic cement which is more particularly adapted to the insulation of pipe fittings, etc.

If a steam line is constructed so that there are sags, low points or pockets, the condensed water will gradually accumulate and reduce the sectional area of the pipe until forced out in more or less large quantities by the steam. This is especially apt to occur if the demand for steam is intermittent and it is from this source that there arises the well-known water hammer caused by the steam carrying a quantity of water along at a high velocity and delivering it against some elbow or valve with considerable impact. The effect of such a rush of water into the cylinders of a reciprocating engine is too well known to require further comment.

All low points in steam lines should, therefore, be properly drained, either by specially designed apparatus for eliminating the water or by "bleeders" as shown in Fig. 1.

Removing the Water of Condensation

The sketches, Figs. 2, 3 and 4, show methods by which the water of condensation is removed. In the several sketches B represents the boiler and E the engine. Fig. 2 shows the simplest method used in piping. The water of condensation flows into the engine with the steam, unless separators V are provided to remove it. In case all of the engines are stopped, as at night, water will accumulate in the pipe and cause trouble when starting the engines, unless the water is drained off by "bleeders." In Fig. 2 the piping to the engine is made from the top of the main, so that the water of condensation will run to the dead end; the small amount of water that is carried over to the engine may be removed by the separator V. The water thus accumulated at the end of the main should be continuously removed by a pump or trap.

In Fig. 3 the pump or trap at S is replaced by a drain pipe, which is connected below the elevation of the boiler water and will drain automatically, provided the drop in pressure in the main is not so great as to maintain a level of water in the drain higher than the point S. If the level maintained is lower than the separators V, then they may be connected to the drain pipe, and in case it is necessary to make a dip in the main, such as at L, the lowest point of this should also be connected to the drain. The entire system will then maintain its circulation; there will be no strains set up in the pipe by alternate heating and cooling, and the whole will be self-draining, whether working or not. When installing such a drainage system, all connections with the drain should be provided with check valves, such as are shown in Fig. 1.

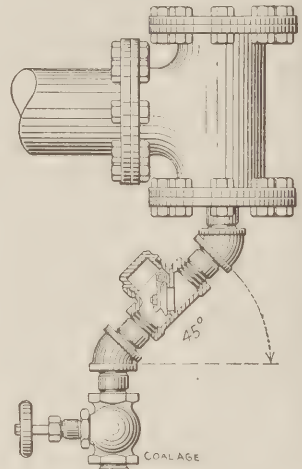

Fig. 1. Check Valve on Drain Pipe

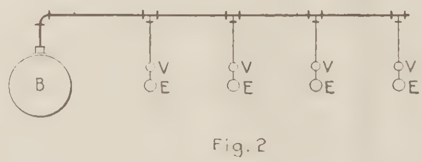

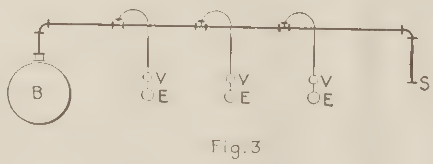

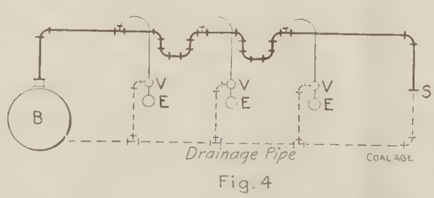

Methods of Installing Steam Lines

Where the elevation of the boilers is sufficiently below that of the engines, as in some of the anthracite collieries in Pennsylvania, the gravity return system of steam piping is feasible, and the results thus obtained are entirely satisfactory in every respect. In a majority of cases, however, the required difference of elevation cannot be obtained and in such instances it is common practice to lead the condensed water back to the feed pumps, which return it to the boiler at a high temperature (about 212 deg. F.). As many drain pipes as possible should be brought together in this way.

Constructing a Branch From the Mains

In leading off a branch from the mains, the connection should always be made at the top of the main, and a horizontal partition at the center of the tee will improve the action of the branch still further, since in case of a quick demand for steam at the engine, the flowing water at the bottom of the main cannot be lifted into the outlet pipe.

It has been the experience of mechanical engineers that the pitch of all the pipe lines should be in the direction of the flow of steam. If a rise is to be placed in the main, a drain should be located at the lowest point just before the rise. In terminating the mains and all important branches, such as at S, in Fig. 4, the ends should be provided with a drop-leg or some other form of low point in the system, and these should be piped to the drainage pump.

A like connection should be made at all fittings which are of such form that the water may collect in them. A method that gives good results in draining mains is to lay a small drainage pipe about 1½ in. in diameter at a suitable distance below the mains and connect it with all the low spots in the piping, and also with the drainage pump.

In order to prevent water entering the mains, from which the steam may have been shut off, a swinging check valve should be used at each connection between the drainage pipe and the main. Such a valve should be placed at an angle of 45 deg., as shown in Fig. 1, so that the valve disk takes a position nearly vertical. In this position it requires practically no head of water to force it open when in action.

Some of the advantages to be gained by a drainage system such as outlined above are the recovery of the otherwise waste heat in the water of condensation, the elimination of strains due to cooling of the pipes when not in use, together with the consequent reduction in the number of pipe leaks, and the delivery of drier steam to the engines, which insures cylinder lubrication with a minimum amount of oil. However, whether or not such an installation will pay at a plant of the usual size in the coalfields, where fuel is cheap, is a matter which will be determined almost entirely by local conditions.

Coal at normal temperature absorbs oxygen, some coals doing so more rapidly than others. Certain unsaturated compounds in the coal combine with the oxygen without producing any great amount of carbon dioxide.

Self Contained Breathing Apparatus

Special Correspondence*

An account of an expert test of self-contained breathing apparatus, grading them according to their availability and recommending certain modifications.

The experimental committee, appointed to investigate certain self-contained breathing apparatus with the object of recommending a suitable appliance for use in the mines of the South Midland coal fields, has issued a report of considerable interest. The members of the committee were well known mining engineers in the Midlands, and the practical investigations were of a somewhat protracted nature, the proceedings being directed by Dr. John Cadman, professor of mining at the Birmingham University, who occupied the position of chairman of committee.

The appointment of the committee was largely the outcome of the Homestead colliery disaster, when the local organization was proved to be so inadequate and the absence of suitable appliances so pronounced that an urgent appeal to the Yorkshire rescue stations for help was rendered imperative. There is abundant evidence in the report now made public that the committee conducted the experiments in the experimental mine of the university with the sole object of securing the most practical information possible relating to rescue apparatus. In the result they may not have given universal satisfaction, for that is scarcely possible where it is necessary to condemn as well as to praise; but that the members of the committee in the prosecution of their labors have sought to give the apparatus a fair trial and to arrive at an honest conclusion regarding the merits of the prospective types examined, will be generally conceded.

Those who have an opportunity to study the report in detail will do so with both pleasure and profit, for it contains some interesting and informing data. Six types of apparatus were examined, and it appears the committee endeavored to reproduce the actual conditions which occur in a mine after an underground fire, and they further undertook such forms of exertion as are then necessary. During each test and each group of tests they collected the following data: The favorable and unfavorable points observed by each wearer during each experiment, the details and nature of the work accomplished, the time the apparatus was worn, the body temperature, pulse and weight of each man before and after the test, the increased weight in the CO_2 absorbent, together with details of the conditions under which each test was conducted.

In parenthesis it may be noted that the youngest member of the committee was 26 years of age and the oldest 50; height ranged from 5 ft. 7 in. to 6 ft. 6 in., and weight from 116 to 195 pounds.

During the progress of the investigation the makers of the apparatus occasionally renewed or refitted defective or badly designed parts. The inquiry was extended considerably, because improvements were made in the apparatus from time to time—improvements which were largely the outcome of the committee's experiments. In this way the task set at the commencement became difficult and seemed almost endless.

For the purpose of the report, the apparatus were considered in two distinct groups, depending upon: (a) The attachment to the face; (b) the gas supply.

Helmets, Masks and Mouthpieces Compared

Under (a) are considered: (1) Helmets or masks covering the whole face; (2) half-masks covering the nose and mouth only; (3) mouthpieces. At the commencement of the tests the committee were all disposed to imagine that the helmet was the most comfortable attachment, but gaining more experience they ultimately came to the unanimous opinion that the helmet is entirely unsuited for use in mines. As explained, helmets as at present constructed, do not permit of a sufficient field of vision, and this renders traveling very difficult, particularly when crawling or looking in an upward direction. The half-mask permits of comfortable breathing, does not restrict the vision, but is very difficult to apply to the face, and the entire muzzling of the nose and mouth and the pressure on the face and chin become depressing and uncomfortable after some time, particularly when the wearer is perspiring.

The mouthpiece, consisting of an india-rubber tube with a flange of suitable size and shape to insert between the teeth and the lips, has much in its favor for use underground, and as far as the experience of the committee goes, is the only suitable attachment. Its favorable features are: The range of vision is not limited; it can be readily inserted in the mouth; it is comfortable and efficient; conversation is possible by slightly distending or raising the mouthpiece, which, even in the most deadly atmosphere, may be momentarily released for expectoration.

Respirable Air Supply Compared

Reverting to classification (b), depending upon gas supply, the Aerolith apparatus depends for its oxygen supply upon the evaporation of liquid air rich in oxygen. The report says: "The supply of oxygen is intermittent, and does not respond to excessive exertion and the expiratory tube occasionally becomes blocked with ice." At the same time it is stated that the apparatus, as improved by Mr. Blackett, seems to overcome this difficulty, and the experiments, so far as they went, were very satisfactory. For reasons given, however, the committee do not seem to favor "this form of apparatus as an efficient type for use in mines."

In the compressed-oxygen type, those giving constant supply (Draeger, Fleuss, Meco) have the oxygen stored in cylinders capable of carrying 260 to 290 liters at 120 atmospheres. The oxygen is supplied for breathing purposes by means of a reducing valve, which may be adjusted, but cannot then be altered while the apparatus is being worn.

In the Draeger and Meco, the reduction in pressure is utilized by means of an injector for circulating the gas continuously through the breathing bag and regenerators; in the Fleuss the oxygen reduced in pressure simply passes direct to the breathing and regenerating bag. The automatic oxygen supply apparatus is represented by the Weg, which theoretically is most efficient, and is of excellent design in many respects; but the committee say "the automatic valve has not reached a state of perfection sufficient to warrant us in recommending it as suitable."

After describing in some detail the tests and experiments, the committee say all the apparatus examined can be used to some extent in mine rescue work, although the experiments revealed defects in construction and principle which are more pronounced in some types than others. To illustrate the various conclusions arrived at they have prepared the table printed on the next page.

Three of the types of apparatus were eliminated by the committee as being the least efficient by comparison, and the Draeger, Meco and Fleuss reserved for the final test as to their suitability, the opinion expressed being that all "are capable of much improvement, and should be modified before being adopted."

Decision of Committee

The claims of the selected appliances are discussed as follows:

"For work under normal conditions,

*The report of a committee of the South Midland coalowners upon an investigation conducted in the mining department of the University of Birmingham into self-contained breathing apparatus for rescue and recovery work in mines after underground fires and explosions. Birmingham (England). Cornish Brothers, Ltd., publishers to the University, 37, New street. Price of report, 5s. net.

and as the apparatus now stand, we are of opinion that the Fleuss is superior to any which we have examined, the order of preference for such work being: 1, Fleuss. 2, Draeger. 3, Meco (Westfalia).

"Under conditions where the temperature of the atmosphere is high, and under long spells of excessive exertion, the Fleuss apparatus shows defects in that the inspiring air attains a high temperature which renders the apparatus uncomfortable and defective. The absolute comfort in distribution of the weight and the flexibility of the tubes has led us to prefer this type under conditions of reasonable atmospheric temperatures and work, but the defect referred to is so serious in an apparatus of such merit that unless remedied, we cannot recommend the Fleuss as suitable under the conditions likely to obtain in rescue work in your district.

"On the other hand, in the more severe tests made in atmospheres with high temperatures, the Meco (Westfalia) and Draeger showed superiority to the Fleuss, the order of preference in these tests being: 1, Meco. 2, Draeger. 3, Fleuss.

"The bad distribution of the weight in both the Meco and the Draeger, and the stiffness of tubes connecting the mouthpiece to the apparatus, render these apparatus clumsy and uncomfortable.

"It will be seen that we favor the Fleuss type on account of its general comfort and adaptability under normal conditions of temperature, and the Meco (Westfalia) and Draeger types in excessively warm and moist atmospheres."

The report contains a specification of apparatus. Appendix I gives details of apparatus with observations. Appendix II examples of instructions for tests. Appendix III proposed scheme for organization of brigades. Appendix IV photographs of apparatus examined.

Pillar Drawing in Contiguous Seams

By Frank Lynde

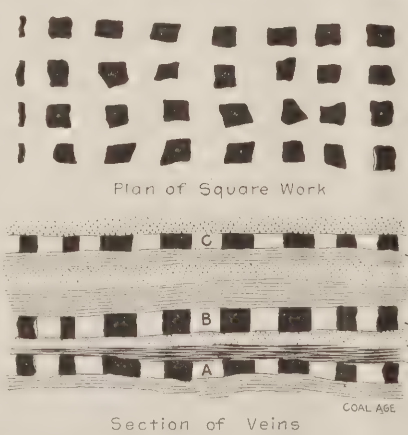
Pillar drawing, even under normal conditions, is a delicate and difficult operation, but when complicated, as here described, the problem is indeed a serious one. The correct solution will be arrived at only by experimenting and a number of methods for robbing are suggested.

An interesting problem in pillar robbing has arisen in the anthracite field, where three closely contiguous seams are being worked. These seams have been practically worked out and the operators are now facing the problem of drawing the pillars.

The accompanying sketch shows the relative position of the seams which are designated at *A*, *B*, *C*, beginning at the bottom. In the case under consideration, these seams have from 100 to 125 ft. of hard sandstone cover and 50 to 90 ft. of wash material. *A* and *C* are about 6 ft. thick, and *B* somewhat thicker. The stratum between *A* and *B* varies from 3 to 10 ft., the material changing from bone to soft sandstone. The stratum between *B* and *C* is from 10 to 25 ft. thick and of a somewhat harder sandstone.

B seam, being the thickest, was the first one to be worked, the mining being done by the room-and-pillar system, with rooms 42 ft. centers and 24 ft. wide. The *A* seam was next worked by the same system as used in *B* seam, and the rooms so driven as to have all pillars directly under those in the *A* seam. The *C* seam was next opened and worked in the same manner as *A* and *B*, so that all pillars in the seams *A*, *B* and *C* formed practically continuous vertical columns, one directly above the other.

The particular workings under consideration are about 50 ft. higher than the shaft bottom, making it difficult to flush with culm. Also the elevation of the high-water mark in this section is about 50 ft. below the top of the hard sandstone above *C* seam.



Working Contiguous Seams

Pillar drawing in contiguous seams having this comparatively thin and irregular parting presents many difficult problems. The case may be considered under the following heads: *A*, Culm Flushing; *B*, Sand and Dirt Flushing; *C*, Flushed with Mine Refuse, and *D*, Square System.

FLUSHING

Under ordinary conditions it would seem the proper method would be to flush the workings of *A* and *B* seams with culm. Then draw the pillars in *C* seam and permit the roof to settle on *A* and *B* seams. Where the stratum between *A* and *B* seams is of considerable thickness, say 7 ft. or over, *B* seam should be robbed next. Where this parting is less than 7 ft. thick, both *A* and *B* seams may be worked together.

An objection to this method would be the necessity of putting down a drill hole or drill holes for flushing, since the bottom of the shaft is below the workings, and it would be difficult to utilize it for this purpose. Care should be taken to have the hole so located as to be readily accessible to all parts to be flushed.

B, Sand and Dirt Flushing—If there are no improvements on the surface, the wash material may be hydraulicked into *A* and *B* seams through a series of drill holes. But it must be remembered that flushing of this kind requires considerable fall in order to be an economical operation. Sand and dirt are not so readily handled by this system as culm, and if the seams pitch less than 6 deg., such heavy material cannot be readily flushed. The supporting power of sand and dirt is greater than that of culm, but the cost is more as more holes are required and more water per unit volume of flushed material, to say nothing of increased labor cost.

C, Flushed with Mine Refuse—If the culm and sand are impracticable, rock and slate may be used, which have been thrown out from the breakers.

The material will, of course, have to be broken up, to accomplish which a crusher with a speed of between 800 and 1200 r.p.m. and driven with 50- or 60-h.p. engine should be used, and in case electrical energy is available the street-car motor type of drive gives good results. Under normal conditions this crusher will handle from 40 to 50 tons of material per hour. In event of material being harder than slate, one of the low-speed crushers should be used. The amount of water required for such operations varies from 4000 to 6000 gallons per ton of material and the installation of such a plant costs from $2500 to $3500.

CRIBS

C, Cribs—Should flushing operations of any kind not be practicable, cribs may be built in *A* and *B* seams, one above the other in every second or third room, or about 100 ft. apart. Such cribs should be from 8 to 10 ft. square and well ballasted with rock. *C* seam can then be robbed, and when *A* and *B* seams take the pressure, the cribs will have a tendency to prevent the pillars from chipping.

D, Square System—If all these systems prove impracticable and in addition it should prove necessary to protect the surface, probably the only remaining method is the square system as illustrated in the accompanying sketch. In this system of mining, the pillars are all cut up into squares sufficiently strong to support the roof pressure. In some instances 50 to 60 per cent. of pillar coal can be recovered by this method. All the pillars should be left one above the other.

In any event, an undertaking of this kind should be so systematized as to divide robbing into a number of sections. One section should be worked at a time as the removal of the pillar coal is extremely difficult and the result uncertain. If a given method fails in one section, employ another method in the next section.

New River Coal Field

SPECIAL CORRESPONDENCE

The past year has been, in many respects, an abnormal one in the New River fields; hardly any new mines have been opened, and, while the output of coal has been good, prices have been uniformly low, in many cases below cost of production. For the first three months of the year prices were fairly well maintained and the operators worked together, but after Apr. 1, everything went to pieces and the coal-mining industry has been in that condition ever since, until the last two months, when the operators, realizing that they could not mine coal profitably under such conditions, began to pull together again. Such a state of affairs has militated against any new developments and the year has been a quiet one in that respect.

The principal development has been along transportation lines, involving the diversion of some 70,000 tons per month from shipment over the Chesapeake & Ohio Ry. to the Virginian. This was brought about by the construction of a line from the Loup Creek district to the Virginian by the McKell interest, the largest individual owner and producer of New River coals.

Another important change of ownership has lately taken place, the Loup Creek Collieries Co., with an acreage of 25,000 and shipments of 400,000 tons per annum, has passed into complete ownership of the H. H. Rogers estate.

Along technical lines there has been little of interest to chronicle. A new mining machine now being experimented with at one of the large mines, will, it is confidently expected, lower mining costs and put out coal in better condition.

The Eccles mines of the New River Collieries Co., which have been under development for the past three or four years, are now beginning to load heavy tonnages. They are now loading about 25 cars daily and, when fully developed, expect to have an output of 5000 tons.

Strenuous efforts have been made during the past year to develop new markets for the New River-Pocahontas coals, the operators realizing that they can no longer depend on New England to take all surplus coal and to cover the output of all future developments. These efforts have met with considerable success and it is believed that 1912 will show a much needed increase in shipments to Mediterranean ports and South America.

Additional Montana Coal Statistics

BY J. B. MCDERMOTT*

As already noted in COAL AGE, No. 13, p. 408, the total production of coal in Montana for the year ending Oct. 31, 1911, was 2,913,397 tons, having a value of $4,903,620.73. The total production for the same period in the previous year was 2,970,246 tons, having a value of $5,405,847.72.

The total number of men employed underground during 1911 was 3132, and the number employed above ground 644, making the total number of coal miners employed in the state during the year of 1911, 3776. The total production per man per day was 3.3 tons. The total amount of black powder used was 1,808,745 lb., and the total amount of dynamite used was 35,220 pounds.

There was one accident for every 76 men employed, and 58,268 tons were produced per accident. There was one life lost for every 224,107 tons produced, or one for every 290 men employed; 3.44 men were killed per thousand employed.

*State coal-mine inspector, Helena, Mont.

Azoturia

This disease, common in mules, is an affection of the liver and blood-forming functions, the prominent symptoms being loss of control of the hnid limbs and the passage of ropy and dark-colored urine. These suggest that the urinary organs are affected but this is not the case. There is an excess of azotous or nitrogenous constituents in the blood and it is from this fact that the name "azoturia" is derived. The disease does not exhibit itself when the mule is kept at pasture, but when it is living on highly nitrogenous food such as oats and is kept long in idleness. A mule thus overfed and underworked is not affected while in the stable; exercise seems to permit the working of the secreted poisons. The quicker breathing of the animal, while laboring, seems to cause a transference of the poison from the overcharged liver and the portal veins of the abdomen.

The following notice relating to azoturia is displayed in the mule and horse barns of the Consolidation Coal Company, in West Virginia.

"It is a disease of too frequent occurrence during the winter months. Stablemen, remember that there is no excuse for the occurrence of azoturia. This disease is caused by feeding working rations to idle horses. Remember that azoturia can be prevented. It takes but 48 hours for this disease to develop.

"All horses idle from any cause whatever must have their grain rations cut down until they return to work. Symptoms of azoturia are plain and should be recognized by stable attendants. The animal is brought out of the stable after having been well fed and rested. He comes out in high spirits, full of life, travels a short distance or works a short time when he becomes lazy, sweats freely, knuckles over at fetlocks and may lie or fall down, perhaps being unable to rise. The muscles of the haunch become swollen and hard. The urine becomes coffee color. Muscular spasms, uremic convulsions and death may be expected.

"Should azoturia occur in your stable, the first thing to do is to call your veterinary surgeon, stating what you believe to be the trouble so that the surgeon may bring proper remedies with him. The second thing to do is to get the horse into a box stall or on the barn floor. Bed him down with plenty of straw or hay, offer him water to drink, turn him from side to side every four hours; blanket him if possible; do not dose a case of azoturia with colic remedy, large doses of spirits of niter or anything else that you have on hand. Call the veterinary surgeon, await his arrival and in the meantime make the animal as comfortable as possible.

Coal Mine Ventilating Equipment

By W. M. Weigel*

The construction and operation of the disk fan are described and formulas derived for its pressure and capacity. The distinguishing characteristics of the Guibal centrifugal fan are also set forth. This is the third of a series of articles on mechanical ventiiators.

*Associate professor of mining, Pennsylvania State College, State College, Penn.

Disk fans have vanes or blades set obliquely to the plane of rotation, as in wind mills or screw propellers for boats. They are usually mounted on a horizontal shaft and are placed directly in the line of the current of air that they move. The difference in pressure on the two sides of the wheel is due to the change in velocity of the air.

The blades are constructed of sheet steel, the inner ends being fastened to a hub on the shaft. The outer ends may or may not be connected by wrought-iron distance pieces but in any case the back of each blade is braced near the top to an extension cf the main hub, or to an extra hub. This is necessary to prevent deflection of the light blades by the air pressure. A cast-iron or sheet-steel casing encircles the wheel with just sufficient clearance to prevent touching. The width of this casing is a little greater than the axial thickness of the wheel.

Fig. 1 shows the general construction of a motor-driven ventilator of this type as made by S. B. Stine, before being placed in position. When installed, the airway or mine opening is built up close to the surrounding ring with either brickwork or tongued and grooved lumber. In the smaller sizes the motor may be direct-connected to the fan shaft. For the larger sizes instead of using a direct or geared motor drive, the fan may be driven by belting to a steam engine, motor or line shaft. This latter method has the advantage of offering less obstruction to the air current.

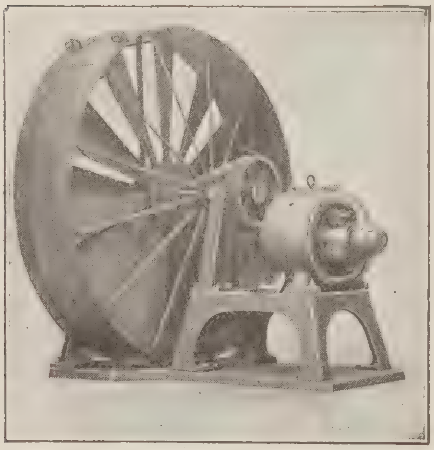


Fig. 1. Stine Disk Fan

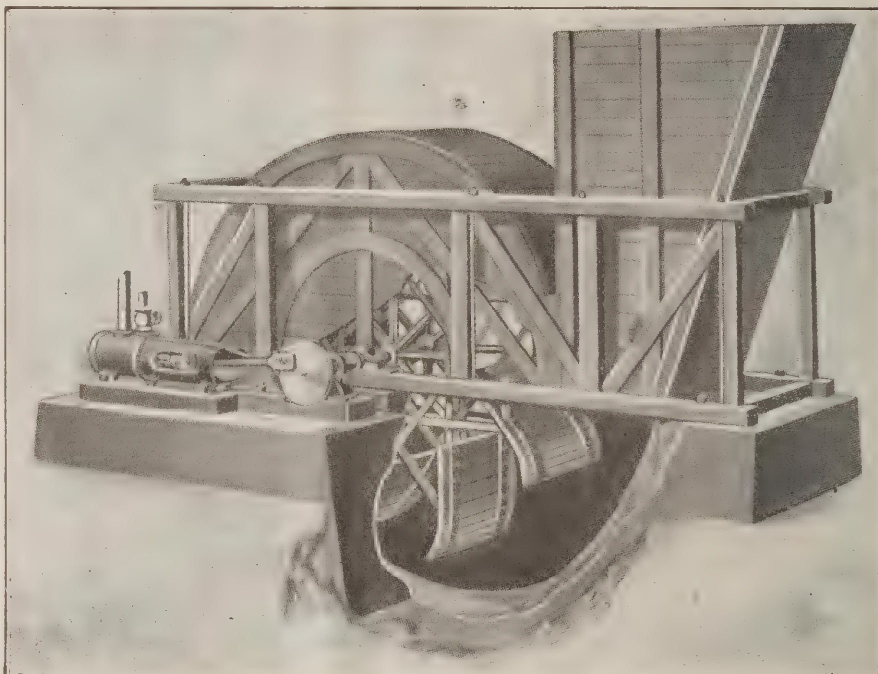

Fig. 2. Guibal Fan with Wooden Blades and Casing

The number of vanes in disk fans varies from 4 to 12. Increasing the number of vanes increases the frictional resistances, but strengthens the action of the fan. It is usually necessary to make the central disk or boss quite large, ¼ to ⅓ the diameter of the wheel, in order to prevent the air from rushing back through the fan at this point, where the pressure developed is the least.

The advantages of this type of fan lie in its low first cost and low cost of installation, no heavy foundations being required; its adaptability to emergency use because of the ease and quickness with which it may be installed; and its fairly high efficiency when working with low pressures. It is not suited to air pressures much above 1-in. water gage or to quantities of air exceeding 80,000 to 90,000 cu.ft. per minute. These fans are made, however, in sizes up to 12 ft. in diameter with capacities of 100,000 cu.ft. of air per minute. As mentioned before they are usually set directly in the airway and are thus liable to destruction from an explosion.

Pressure and Capacity of Disk Fans

The blades of disk fans may be considered as sectors of a helix, and in fact they follow the lines of a helix to a certain extent, the angle which the blade makes with the plane of rotation increasing as the center is approached.

Let

α = Angle made by the blade with the plane of rotation, at any distance from the center.

r = Radius at this point.

then $2\pi r \tan. \alpha =$ the pitch of the blade, and disregarding the friction of the air on the blade, a particle of air would be moved forward a distance equal to the pitch in one revolution of the wheel, if the blade was a continuous helical surface; that is, it would be moved forward a distance $2\pi r \tan. \alpha$ normal to the plane of rotation. Letting $n =$ number of revolutions per second and $v =$ the velocity of the air leaving the face of the wheel in feet per second, then

$$v = 2\pi r n \tan. \alpha. \qquad (1)$$

The velocity v is equivalent to a total pressure of $\sqrt{2gh}$ where h equals the head in feet of a column of air necessary to produce the velocity v. In order to make uniform comparisons, the weight of a cubic foot of dry air at 32 deg. F., at the sea level should be taken as a basis. Under these conditions a cubic foot of air weighs 0.0807 lb. and the pressure equivalent to a velocity v is $p = 0.0807\ h$, where

$p =$ Pressure in lb. per sq.ft.
and

$\frac{p}{5.2} =$ Pressure in in. of water, also let

$i =$ Water-gage in inches,
then

$p = 5.2i$,
and

$$h = \frac{5.2\ i}{0.0807} = \frac{v^2}{2\ g},$$

from which

$$i = \frac{v^2}{128.86\ g}, \text{ or } v^2 = 128.86\ gi.$$

Theoretical and Actual Pressure and Capacity

Substituting the value of v^2 in equation (1)

$$i = \frac{(2\ \pi r n\ tan.\ \alpha)^2}{128.86\ g}. \qquad (2)$$

This is, of course, the total theoretical pressure attainable, that is, velocity pressure + static pressure, and if the fan is operated against a resistance, all the energy expended will not be converted into velocity alone. The pressure developed will be less than (2) because of the friction of the air on the blades, and the "slip" of the fan. The actual pressure will vary with the design of the fan, and the conditions under which it operates, and will be from 60 per cent. to 75 per cent. of that found from equation (2) where i does not greatly exceed one inch.

In order that the pressure or velocity of the air may be the same over the entire face of the wheel, the value $2\pi r\ tan\ \alpha$ must equal a constant, but this condition requires too great an angle of the blade near the center of the wheel. To overcome this difficulty the large central disk or boss previously mentioned; is employed and at the same time the ends of the blades fastened to this are not given the full pitch. The pressure actually developed is probably that due to the conditions existing at the mean of the inner and outer radii.

The pressure increases as the square of the tangent of the angle of the blades but a point is soon reached on increasing this angle, beyond which the shock of the air on entering the blades and the consequent churning and eddying has an even greater effect on reducing the pressure and decreasing the efficiency.

The theoretical capacity of the fan is the product of the velocity by the area of the annular space between the inner and outer circumferences.
Let

$r_1 =$ Radius of the central boss or hub;
$r_2 =$ Radius of the tips of the vanes;
$Q =$ Capacity in cubic feet per second;
then

$$Q = \pi v\ (r_2^2 - r_1^2) \qquad (3)$$

Since the velocity varies with the ratio of the velocity pressure to total pressure (that is, velocity pressure + static pressure) the volume discharged will approach nearest the theoretical when both sides of the fan are open to the atmosphere, and will be zero when the fan is discharging into or exhausting from a closed space.

The angle of the blades with the axis of rotation varies from 20 deg. to 35 deg. in the different makes of fans, and to some extent depends on the work the fan is to do.

Guibal Fans

Many forms of centrifugal fans are used at American mines, almost as many forms as there are different manufacturers of fans, but each has certain characteristics by which it may be classified as belonging to one of the following groups:

a. Guibal fans.
b. Capell fans.
c. Modern steel-plate fans.
d. High-speed or multivane fans.

The Guibal fan was one of the first forms used and is distinguished by its large diameter and its comparatively few blades, which are plane surfaces or surfaces curved only slightly. Fig. 3 shows the outlines of a typical Guibal fan, 35 ft. in diameter, and 11 ft. 8 in. wide, with inlet on one side only. As seen in the illustration the blades terminate at the circumference of the inlet, and slope backward about 30 deg. from a radial position. The light double lines extending across the inlet show the arms and bracing of the blades. These are bolted to cast-iron spiders keyed to the fan shaft as illustrated in Fig. 2, which shows a Guibal fan with part of the casing removed.

Referring again to Fig. 3, it is seen that the inlet is approximately one-half the diameter of the fan wheel, and that the spiral casing follows the circumference of the fan after leaving the point of cutoff, and then gradually enlarges, the expansion or discharge area at the cutoff being small in comparison with the diameter of the fan. This is another distinctive feature of the Guibal fan.

There are no cheek plates or annular disks connecting the sides of the blades, the side casing fitting to them as closely as possible without actually touching. In Fig. 3 it is seen that the blades curve forward at their tips to a radial position, while in Fig. 2 they curve backward; there is no recognized standard in respect to this.

Formerly the blades, casing and chimney were made of wood, and many fans of this construction are still in use and giving excellent service. All-steel construction is better, however, because it is more durable, has less leakage and is fireproof, a most important consideration. These fans may have an inlet on each side, but more often are provided with a single inlet. They are built as small as 10 ft. in diameter.

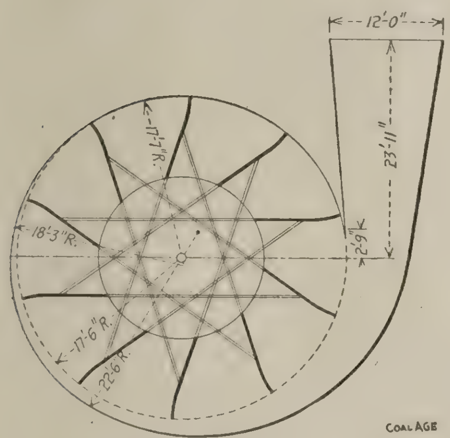

Fig. 3. Guibal Centrifugal Type

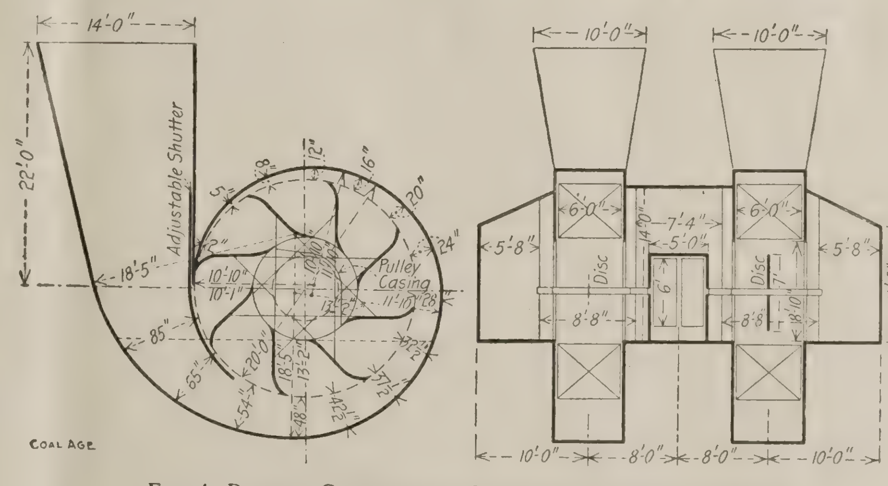

Fig. 4. Double Centrifugal Fan with Cutoff Shutter

The Cutoff Shutter

When air is being discharged into the spiral casing from between two blades, the pressure is on the front of the blade. Now as the tip of the blade passes the point of cutoff the discharge of air is suddenly stopped, causing more or less shock, and a sudden removal of the pressure from the front of the blade. This condition tends to cause vibrations injur-

ious to the fan, and pulsations in the air. To overcome it what is known as the Walker Anti-Vibrations Shutter was introduced.

This device consists of a flexible slide introduced at the point of cutoff, and supported between guides on the inside of the casing, which are curved to a circle of such size that the blade tips will just clear the shutter. By raising or lowering this sliding shutter the point of cut-off is changed and the discharge area is varied to suit the work the fan is doing. The lower edge of the shutter is notched in the form of an inverted *V*, the notch starting from each lower corner. Thus a blade on reaching the lower end of the shutter has the area of this notch through which to discharge the air in front of it, and the area gradually reducing as the blade advances, the air is discharged gradually and shock prevented.

The location of the shutter is shown in Fig. 4, illustrating the outlines of a Guibal fan in which the tips of the vanes bend backward and the inner ends forward, so that the air may enter from the inlet with less shock. This installation at the Susquehanna Coal Company's colliery, Nanticoke, Penn.,* consists of two fans, as indicated in the illustration, drawing air from one mine. They are mounted on separate shafts, but are driven by one duplex engine.

*"Centrifugal Ventilators," by R. V. Norris, *Trans.* A. I. M. E., Oct., 1891.

From the dimensions given in Figs. 3 and 4, it is seen that the spiral casing is not a true mathematical spiral, which would be difficult to lay out in practice, but consists of arcs of circles with increasing radii. The diameter of the inlet is approximately one-half of the diameter of the fan wheel, and the width of the blades for single-inlet fans one-third or less of the diameter.

Guibal fans have good efficiencies, and are suitable for large volumes of air at medium water gages, that is, 2 in. to 5 in. On account of their large diameter and slow rotative speeds they are especially adaptable to direct engine drive. They have found their largest application in the anthracite district of Pennsylvania.

United Mine Workers' Convention

Special Correspondence

The convention at Indianapolis will determine the stand that will be taken by miners with regard to making new wage contracts April 1, in bituminous and anthracite coalfields throughout the country. Daily reports of the proceedings by our own representative.

Opening Sessions on Tuesday

Fourteen hundred delegates, representing 314,000 organized coal miners, gathered in Tomlinson Hall, Indianapolis, Jan. 16, for one of the most important conventions and conferences in the history of the coal industry of the United States and Canada, the 23rd annual convention of the United Mine Workers of America. One of the chief purposes of the convention will be to formulate the demands that will be made by the miners when their representatives meet the mine operators to negotiate and establish new wage contracts for both the bituminous and anthracite fields.

President John P. White called the convention to order and the opening session was given up to addresses of welcome by representatives of civic and labor associations. Former Mayor Charles A. Bookwalter spoke for the Central Labor Union of Indianapolis. He said the miners were confronted by a question of great importance to the common good and their action would have a large influence in the industrial world. Other speeches of welcome were made by Rabbi M. M. Feuerlicht, representing Mayor Shank and Gov. Marshall. President White expressed the appreciation of the entire membership for the cordial welcome extended by the City of Indianapolis.

At the afternoon session the committee on rules and organization made a report providing that sessions should be held from 9 to 12 a.m. and from 1:20 to 5 p.m. Speeches were limited to five minutes and a rule made that no member be allowed to speak more than once on any question until all who wished to be heard had spoken; disorderly conduct to be punished with a reprimand and expulsion from the hall. Cushing's manual was adopted as a parliamentary guide.

President White read his annual report and Vice-President Hayes and Secretary-Treasurer Perry followed with their reports. President White said, among other things, that the miners will most certainly not consider any reduction in their present wage scales, but will strive for such advances in pay as seem possible to achieve; adding: "Probably no convention of the United Mine Workers in recent years has assumed a greater obligation than will this one if it fully discharges its duties to those who compose our membership."

Mr. White also said that now, practically on the eve of the expiration of the wage contracts, the attention of the whole Union membership and of the entire country will be centered on the deliberations of this convention and, "It will remain for the convention to outline a policy that will best meet the needs of the people and adopt a plan that will redound to the benefit of our membership everywhere. Our scale committee will do well to consider the responsibilities that devolve upon it."

The president then described the condition of the organization at the time when he took charge and spoke of conditions now, pointing out the growth and improvements made during the past year. The causes of the numerous strikes were discussed and while refusing to surrender the right to strike, he advocated a more reasonable course. His report showed that the United Mine Workers have a paid-up membership of 266,256, which is an increase of 24,864 over the previous year.

In conclusion, President White recommended that the organization renew its affiliation with the World's Mining Congress, which connection was discontinued in 1909.

Socialism Introduced

After going on record as favoring government ownership of industries, the socialists among the delegates introduced a resolution indorsing their party as "the political party of the working class," but the motion met with resistance and was defeated. Stormy debate occupied the whole of two sessions of the convention. Action was deferred on a resolution providing that the United Mine Workers should withdraw from the American Federation of Labor, condemning the National Civic Federation as an agent of capitalists and sharply criticizing the officials and leaders of the Federation of Labor for coöperation with the Civic Federation.

Because the organization had stipulated that it would be nonpolitical, the resolutions committee reported that it had refused to concur in the resolution committing the organization to the Socialist party, and offered as a substitute one declaring that "it would be well if workers would unite in the political as well as the industrial field." This brought about another discussion that lasted the remainder of the day.

John Walker, president of the Illinois miners, speaking for the socialists, intimated that if necessary an effort would be made to amend the constitution so that the national union could indorse the Socialist party. In a fiery speech he declared: "If you will not listen to our pleadings you will pay the cost." The "capitalistro parties," he said, possess the

power to enforce injunction, and to kill if necessary, and he urged the working class to seek political power "so that if it is necessary to use the injunction and the bayonet they will be used in defense of your firesides."

President Mooney, of the Missouri organization, protesting against the campaign of the socialists in the convention, declared the delegates could not pledge the Mine Workers of America to any political party. He said the constitution provides that religious or political subjects shall not enter into the deliberations of the convention.

Consolidation Possible

Consolidation of the Western Federation of Miners and the United Mine Workers is a strong possibility and was prophesied by John A. McKinnon, of British Columbia, and Edwin Young, of Montana, who addressed the convention. Both speakers represented the Western Miners as fraternal delegates to the convention. "All that is necessary," they declared, "is to refer the matter to the Westerners and surrender the charter of the American Federation of Labor, thus clearing the way for consolidation." The proposed amalgamation would result in the most powerful individual labor union in the world, with half a million members or more. The delegates cheered the prophecy.

In the report of Vice-president Hayes it was shown that while the United Mine Workers have a membership of 300,000 there are about 450,000 coal miners that are unorganized; hence, it is a serious question whether they should hold out for a general national agreement, when in some districts smaller bodies of operators are willing to come to terms. The scale committee, appointed Jan. 18, went into session Friday and is expected to report on or before Jan. 25.

Factional Dispute

The report of the credentials committee afforded an opportunity for airing the factional troubles which have nearly disrupted the organization of District No. 5, western Pennsylvania, during the past four or five years. Fiery oratory was fanned to a white heat when the committee reported that the Gibbons delegates were not entitled to seats in the convention on the ground that the three men selected were not members of the organization, and recommended the seating of the Feehan delegates. Robert Gibbons, Abe Kephart and James Sabin, the three deposed delegates, fought every inch of the way until the vote was reported in favor of seating their opponents.

Unusual interest was shown in these debates, because the Feehan-Gibbons fight is said to have been the most serious factional controversy that has arisen on the convention floor in many years. Conservative labor leaders expressed regret at the evident display of unharmonious spirit in the labor movement, and predicted defeat of the organization's plans if factional fights continue.

Interstate Wage Conference

Although the Feehan-Gibbons debate occupied approximately all Saturday's session, President White reported that his plans for the revival of the old interstate joint wage-scale movement have proved successful. He said the operators have promised to attend the meeting of the joint wage-scale committee to be held here Thursday, Jan. 25. He also said that miners of the anthracite field have demanded an eight-hour working day, a one-year contract, and a 20-per cent. increase in wages. His announcement that the interstate joint movement will be revived brought forth much applause as many of the delegates have feared that the operators would refuse to enter into a joint conference.

The miners indorsed a resolution to the effect that the organization should strive to have enacted compensation laws in the various states where mining is conducted. A proposition to start an international sick and accident fund was voted down, and several resolutions in regard to membership in the National Civic Federation of Labor were carried over until Monday. It cannot be said that a great deal was accomplished by the convention during the first week.

Scale Committee Appointed

The delegates to the miners' convention took up the matter of amending their constitution, Monday morning. Just before noon adjournment, President White appointed a joint wage-scale committee to go into conference with the operators, Thursday, Jan. 25. If the work of the convention is completed before a report is made by the members of the scale committee, the delegates will remain until a report is secured so as to ratify or reject the work of the conference.

The convention is greatly elated over the fact that the operators agreed to come to Indianapolis for a joint conference. The miners' prospects are declared to be brighter than they have been for years. There is an abiding hope that a joint wage scale will be speedily agreed upon.

Constitutional Amendment

An effort was made, Tuesday, by the socialist element, to frame the new constitution so as to shear the international officials of much of their power and place it with the rank and file to be expressed by the referendum vote. In some instances the effort was successful, but in the more important matters the authority was left with the international president and other officials.

After the next annual elections international officers will be chosen every two years instead of annually. A report of the constitution committee to this effect was embodied in the new constitution after a long debate in which an effort was made to keep the clause out of the constitution until it had received the endorsement of the membership through a referendum vote.

Almost the entire day was devoted to the constitution committee's report. It is thought that at least two days more will be required to pass or reject the proposed constitution.

The Year 1911 in Indiana

Special Correspondence

With five important strikes affecting some 2850 miners, in addition to numerous minor difficulties between the operators and the men, the year of 1911 in Indiana was one of the hardest in a long period for both miners and operators.

There are 18,000 miners in Indiana qualified to mine coal. Beginning with last May, the largest strike period in the year occurred when seven mines, the properties of three separate companies, were idle, 1500 men being ordered on strike. These were the Little Mining Co., of Green County, the Jackson Hill Co.'s mines, near Clinton, and the Coal Bluff Coal Co.'s mines, at West Terre Haute. This was a long fight and many joint meetings were held, but failed to bring a settlement, and the final decision of President Taylor, of the Illinois Operators, and President White, of the United Mine Workers, left the real issue involved in the strike unsettled. There were at the close of the year 550 men on strike in the Bicknel field in southwestern Indiana.

A far greater loss to the miners resulted from the shutdown, due to a lack of demand for steam coal. In many of the mines of the state for six months or longer, the average work was but two or three days per week, while only a small proportion of the mines worked with anything approaching regularity until the last few weeks of the year.

Taking as a basis that 9000 of the 18,000 miners of the state were out of employment through this cause, and we have as a conservative estimate that 2,700,000 days' work was lost by the Indiana miners during 1911. This is based on the estimate at the time of the worst condition that 50% of the miners were out of employment from all causes. Conditions the last few weeks of the year were much improved, although there were a number of mines running on slack time.

Two mine conventions were held during the year at Terre Haute, the first special convention in the history of the state being convened in May. The government rescue car made three visits to Terre Haute during the year and was

busy throughout the districts. First-aid teams were organized in the Terre Haute field.

The output of coal for the first half of the year was estimated at not more than 25% of the capacity of the 18,000 miners in the state. A part of the congested conditions in the Indiana coal fields is due to the presence of 2500 miners who came from other fields in 1910, during the prolonged Illinois strike, and remained in the state during 1911. The total production of coal in Indiana for 1910 was 18,389,815 tons, with a spot value of $20,813,659. The figures for 1911 are not available, but it is estimated that the total production will fall short of the 1910 output by several million tons.

World's Consumption of Bunker Coal

The suggestion that the opening of the Panama Canal may render feasible the establishment of a great American station for supplying coal from the mines of the United States to vessels of the world lends interest to an estimate prepared by the Bureau of Statistics, Department of Commerce and Labor, of the coal consumption on the oceans of the world. The statement estimates the coal consumed on the oceans of the world at approximately 75 milion tons per annum, valued at over 250 million dollars.

An exact statement of the quantity of coal consumed by the merchant marine and navies of the world cannot be made, owing to the fact that comparatively few countries state in separate terms the quantity of coal supplied to vessels for their own use, or for "bunkering" purposes.

The United States statistics show about 9 million long tons supplied to vessels at ocean ports to be placed in their bunkers for their own use, and the British reports show about 20 million long tons supplied to vessels in the foreign trade and 2½ million tons to vessels in the coastwise trade. This would make for the two great coal-producing countries of the world—the United States and the United Kindom—a total of over 30 million tons supplied directly to vessels for "bunkering" purposes.

In addition to this, however, a considerable percentage of the coal sent out of Great Britain as "exports" passes to ports and stations in various parts of the world from which it is finally supplied to ocean vessels for fuel purposes. A paper presented before the Royal Statistical Society of England by D. A. Thomas, M. P., stated that:

> The great bulk of our export of coal is for the use of steamships, and it is within the mark to say that over half of our exports are for navigation purposes. . . . Cardiff alone ships over a million tons annually to Port Said, over a half million to Malta and Gibralter, about the same quantity to Cape Verde and the Canaries, over 300,000 to Colombo, and large quantities to Aden, practically the whole of which goes to bunker steam vessels calling to coal at those depots.

As the British exports of coal, aside from that recorded as supplied to vessels for fueling purposes, amounted in 1910 to over 62 million long tons, the above quoted estimate would seem to justify adding to the 30 million tons recorded as bunker coal by the United Kingdom and the United States another 30 million as the share of British exports which finally becomes bunker coal.

While the Bureau of Statistics is unable to state the share of American coal exports which become vessel supplies (aside from that actually reported as bunker coal and not included in the export statement) it is quite probable that a considerable percentage of the coal from the United States which passes to the West Indian Islands and the coast of Mexico is used for vessel fueling. Add to this the more than 2 million tons supplied by the Japanese mines to vessels engaged in the foreign trade, the more than 1 million tons supplied from Australia, the nearly 1 million tons supplied from India, plus the estimated consumption of about 3 million tons by the navies of the world, and the Bureau of Statistics estimate of an average of 75 million tons consumed on the oceans of the world seems a conservative one. As the valuation of the coal exported for steaming purposes averages about $3.50 per ton, the further estimate of the value of the coal used on the oceans of the world—over 250 million dollars per annum—seems also a conservative one.

The Wyoming Mine Explosion

Reported by Telegraph

On Ja 20, at 4:10 p.m., a small local explosio occurred at the No. 4 mine of the Ker erer Coal Co., located at Susie, Wyo. Over 100 men were in the mine at the time of the explosion, of whom five were killed and 18 slightly injured.

Location and Geology

The town of Susie is located about eight miles north of Kemmerer, Wyo., on a branch of the Oregon Short Line R.R., in the extreme southwestern part of the state. It is about 270 miles, by rail, north of Salt Lake City, and 440 south of Butte, Montana.

According to the U. S. Geological Survey map "Coalfields of the United States," this field is described as the Hams Fork Region of the Rocky Mountain Province. The coal occurs in the Fork Benton division of the Colorado formation, belonging to the Upper Cretaceous series. The measures have a strong westerly dip varying from 15 to 35 deg.

The coal is a high-grade bituminous and ranks as one of the best fuels in the West. It is described by the U. S. Geological Survey as "an excellent fuel for all purposes, quite hard, breaks with a bright fracture and stands storage and long transportation with but little loss."

Mining Methods

There are three principal operating companies in this field; the Union Pacific Coal Co., a subsidiary of the Union Pacific R.R. Co., operating in the southern part; the Diamond Coal & Coke Co., a subsidiary of the Amalgamated Copper Co., operating in the central part; and the Kemmerer Coal Co. (at one of whose mines the explosion occurred) operating in the northern part.

Mining is done entirely by means of slopes sunk approximately on the dip and having water-level entries turned every 350 to 450 ft. From these entries rooms are driven to the rise generally on 60-ft. centers, with 35-ft. rooms and 25-ft. pillars, with barrier pillars at intervals of from 2 to 6 rooms, depending on the roof conditions. Horses are used for haulage on these entries and the ordinary engine-plane system is used on the slopes. Small quantities of firedamp are occasionally found which burns in a peculiarly sluggish manner when ignited. The coal is shot off the solid almost without exception.

The Explosion

This district has been particularly free from any extensive explosions, having been the scene of only one other serious disaster, that at Diamondville, Dec. 1, 1905, which cost the lives of 18 men. The quantities of gas encountered were not considered excessive, and the mines are, without exception, under competent management and carefully handled.

The No. 4 mine of the Kemmerer Coal Co., the scene of the present disaster, is a comparatively new one, having been under development only some two or three years. The mine was opened on the usual slope system and worked by the room-and-pillar method. It is well equipped with modern appliances throughout.

The explosion is supposed to have been the result of a blown-out shot in the second north entry, and occurred just as the day shift were going off. An unusual feature of the disaster is the fact that the fatalities appear to have been confined entirely to Americans.

The mine rescue car No. 4 was on the scene of the accident within an hour, and together with assistance from the neighboring mines, rendered valuable aid in the rescue work. The mine was only slightly injured by the explosion, and all the bodies have been recovered.

COAL AGE

Labor Unrest

Time, with no leaden heel, seems hastening the approach of a general stagnation of the coal business consequent on a strike in which the two largest coal-producing nations, and one that ranks sixth in the list, may well be involved. The United States, Great Britain and Belgium produce together 65 per cent. of the production of the world.

The miners of Great Britain, on Jan. 10, by an overwhelming vote of 445,801 to 115,921, decided to cease work on March 1. They hope to get the mine owners to consent to a minimum wage, but this the operators are not likely to concede without a bitter struggle. They do not feel able to make any large concessions, because the national competitor, Germany, has for years been displacing English coal, the output of that country having risen 200 per cent. while England's production has only advanced 68 per cent.

The profits have recently been reduced by the operation of the eight hours' act, and the English operators feel that they cannot bear any further burdens. In view of the fact that the production of the English mine worker is less than half as much as is produced in our anthracite regions per inside man employed, and almost exactly one-third of the average output per man inside in the bituminous regions of this country, it might be suggested that speeding up would be a possible solution of the miners' difficulties and not a minimum wage.

The later reports appear to indicate a feeling of anxiety on the part of the miners, as if they had somewhat exhausted their spleen by the vote cast, and are beginning already to look with apprehension toward the titanic struggle. Moreover, questions of patriotism also intervene. A naval war depends on steam, and, furthermore, taxation could not well meet the demands of a war if business were at the same time stagnated by internal strife. This complication always results in the mine owners and mine workers being alike compelled by public opinion to suppress their variances on behalf of the preservation of the empire. Realizing the gravity of the situation, the British government has sought to place contracts in America, without much avail, owing to the difficulties in our own labor situation.

The Belgian strike has not yet involved the whole kingdom, and all differences may be adjusted before April 1, when our own strike is anticipated. There is also a strong feeling of unrest in Germany, though it is not so manifest as in Great Britain and Belgium.

Home troubles may yet end in peace. The miners in those states where higher wages are paid and the unions are strong, will think twice before they decide to strike and thus aid the operators of those districts where the men will not strike and where lower wages prevail. It is not likely that the miners of West Virginia will lay down their tools when those of Pennsylvania, Ohio, Indiana and Illinois come out on strike. Hence, the end of a long struggle would inevitably show West Virginia more strongly entrenched than ever in the Northern trade. That state could well increase her output 50 per cent., and it is a safe prediction that those concerns which can forecast their coal demands will prefer to place their contracts in West Virginia, because there alone, is to be found a certainty of a steady fulfilment of contracts placed.

At times it seemed to be a safe prediction that the miners in the unionized fields would have either to accept a reduced wage at home or migrate to West Virginia and receive a reduced wage there. Nevertheless wages have risen steadily in the union fields, the operators have struggled along, in many cases increasing their indebtedness year by year. Whether the miner has gained by the increased wage is, of course, a question. He has undoubtedly suffered by working less steadily than he would, had his wage been less. But such a statement is hard to prove, and the miners so far have not realized it, finding that the days worked at mines where the unions are

strong are not materially less in number than in mines of the unorganized fields.

The action of the miners in raising wages in the northern coal fields, while leaving the state of West Virginia to its own devices, has brought the West Virginia coal field rapidly to the front as a producer. This artificial stimulus of a section of the whole industry of the nation has caused the section so stimulated to overrun all markets, with the result that in face of glut and fierce competition the northern operators are kept from raising their rates of pay. Had the unions been less prodigal of their power, their potency to increase wages would have been more marked today.

Old Hednesford Disaster

The disaster in the Old Hednesford mine of the Cannock Chase Co., Ltd., of England, Dec. 14, 1910, shows how much carelessness even today is to be found around some coal workings. The Cannock Chase Co. kept a house in the Bass seam, where the boys were in the habit of going to fill their lamps. Each boy filled his own. The bucket, that caught the waste from the filling tank, caught fire and the blaze rapidly spread. The boys had been in the habit of throwing oil-soaked wicks on the ground, when they removed them from their lamps, and consequently the condition of the floor of the heading was favorable to the spread of the conflagration. Some thirty cars stood on the track, and the man who attempted to extinguish the blaze could not move them. Consequently, when the fire spread beneath them it could not be stamped out. In a short while the cars themselves caught fire.

The separation doors between the shafts were opened by order of J. Collier, the foreman of the Bass seam, in order that the smoke and carbon dioxide would not pass through the workings, but later, at least 45 min. after the fire started, the under-manager came down, and ordered these doors shut. At the inquest he stated that he did not realize that this action would force the products of combustion into the mine and on the escaping men. Five men were asphyxiated. The jury returned a verdict recommending that a man be placed in charge of the lamp house, and that sand be stored for use in subduing such a blaze should it again occur.

It does seem that the financial interests of the coal company, even if there were no more potent reasons, should favor a more complete remedy, to wit, the removal of the lamp house altogether. But there is a valuable suggestion here, that where oil is apt to be spilled by leaking cars or other causes, a small body of sand and a shovel should be kept ready for smothering any incipient blaze. Furthermore, it would be well to strew sand over all oil droppings, later removing the oil-soaked sand at frequent intervals.

Natural Schistification

The recent explosions at Adrian and Briceville call forcibly to one's attention the fact that the latent powers of coal-dust are rarely exhibited to the full in these catastrophes owing to conditions not favoring perfect combustion. When one regards the violence at Bruceton, Monongah and Harwick, one realizes that those explosions were of an entirely different order from those which have recently occurred.

In order to make plain the severity of one of these, that at the Bruceton experimental station, it might perhaps be well to preface further remarks by stating that, to all appearance, the voids above the concrete which lined the galleries at that mine were not large enough to explain such a lift in the concrete arching as undoubtedly took place. The buckling of the reinforcement has automatically registered the fact that in one place the arch was raised twelve inches. How could this be, unless the whole overlying earth were likewise raised, and this is the explanation now finding favor.

It must be conceded that the conditions at the Bruceton mine were highly favorable for a spectacular exhibit of the explosive power of coal dust. It is true the headings were short and the force of the explosion was thus somewhat reduced, but had more dust per lineal foot been present the disruptive energies within the mine could not have been greater, though an increase of violence would have been shown, had all the headings been charged.

In the main return gallery the charge, if spread over the floor, would have covered it with a layer only 0.021 in. thick, or if the sides had aided the floor to hold the same charge, they would have been covered with an equal coating of 0.008 in. of dust. The equivalent floor charge in the oblique gallery where the dust was only distributed in half-pounds per running foot, would be 0.013 in. deep while the floor and rib charge would be less than 0.005 in. thick.

These are apparently extremely light charges. An off-hand judgment would not view them as constituting a large amount of dust. But every ounce was of such fineness and was placed in such manner as to be immediately available.

Moreover, the fuel was in such quantity that the oxygen present was insufficient to permit the carbon and hydrogen of the coal to burn completely to carbon dioxide and water. Much fuel remained unburned when the blast belched from the mouth of the mine.

Other exploded mines have had as much dust of like nature and fineness, as Bruceton; to have had more would not have increased the violence. Probably this dust was not so ingeniously distributed. But, in any event, the dust was there and its failure to do more damage must be ascribed to some form of natural schistification or dampening.

Where motors are used, the heading soon contains a large amount of sand which has been ground to fine caliber and deposited near the rails.

For example, at one mine in central Pennsylvania, with a rolling, uneven floor, no less than three gondola cars of sand are ground to powder beneath the wheels of the electric motors every month. And it was noticeable that the deep dust in the Adrian mine consisted largely of such sand dust and natural sand. In other mines with a shale roof, the constant dropping of top-rock serves, especially when it tends to slake, to schistify the floor of the mines. This found exemplification in a marked degree at Vivian, W. Va.

Schistification may be a cure for explosions, but with the leaky cars at present in general use, it would seem to be only an insufficient palliative.

There seems every probability, in the view of the British chief inspector of mines, that had electric hand lamps been in use at the Whitehaven and Hulton collieries, in England, the terrible disasters which took place there in 1910, would not have occurred. In the case of both accidents, there is little doubt but that the igniting cause of the explosion was the gauze safety lamp.

Questions of Indiana Examinations Held at Terre Haute, January 12, 13, 1912

Mine-boss Examination

Ques.—Does coal dust, when suspended in air, give to the air explosive properites?

Ans.—The finely divided dust of many bituminous coals is highly inflammable. When this dust is floating in air and exposed to a flame of sufficient volume and intensity, there are present all the conditions necessary to burn the dust with explosive rapidity. The finer and more inflammable the dust, the more rapid the combustion and the more violent the explosion, other conditions being the same. This condition is spoken of as an explosive condition of the mine air.

Ques.—(a) When is shaft timbering required and when is it not required? (b) What are buntons and what is their use?

Ans.—(a) Shaft timbering is generally required at the surface in all shaft sinking while passing through the drift overlying the harder strata. Timbering is also required, as the sinking proceeds, wherever the strata are not self-supporting under the conditions existing in the shaft. In other cases, only such curbing and buntons are required as are necessary to make the shaft safe and to support the guides, column pipes, signal wires, electric cables and other shaft equipment.

(b) Buntons are the heavy cross-timbers put in a shaft to support any part of the shaft or its equipment, or to support a temporary scaffold or staging.

Ques.—There being 43,560 sq.ft. in an acre and 27 cu.ft. to a ton, how many tons of coal may be gotten from a tract of five acres, the coal seam being 6 ft. thick and allowing 20 per cent. for loss?

Ans.—The cubic contents of this five-acre tract and 6-ft. seam is 5 × 43,560 × 6 = 1,306,800 cu.ft. Then, taking the average weight of Indiana coal as 1 ton per cu.yd. (27 cu.ft.), and allowing for a loss of 20 per cent. or ⅕ of the contents of the seam, the net weight of coal taken out of the mine would be

$$\frac{4}{5}\left(\frac{1,306,800}{27}\right) = 38,720 \textit{ tons}$$

Ques.—What are the conditions that should determine the widths of rooms and headings and the size of pillars, in mine workings?

Ans.—The width of a heading is determined (1) by the requirements and use of the heading, size of mine cars and kind of haulage employed, or quantity of air to be circulated in airway; (2) by the nature of the roof and floor, the roof pressure, and the length of time the entry must be kept open. The width of rooms is determined by the depth, thickness and inclination of the seam; the character of the roof, floor and coal; the system of mining adopted and length of time the rooms must be kept open. The size of entry and room pillars, alike, is determined by the data last mentioned and the width of the openings they protect.

Ques.—(a) An airway 16.7 ft. wide, 8.9 ft. high, is passing 65,000 cu.ft. of air per min.; what is the velocity of the air current?

(b) If powder smoke requires 2 min. and 17 sec. to travel 149 yd. in an airway 10x12 ft., what quantity of air is passing in the airway?

(c) In an airway 6x7 ft. the anemometer registers 75 ft. per min.; what quantity of air is passing in the airway? Show each step in the calculation of these three questions.

Ans.—(a) The sectional area of the airway is 16.7 × 8.9 = 148.63 sq.ft. The average velocity of the air current in this airway is then

$$v = \frac{q}{a} = \frac{65,000}{148.63} = 437.3 \textit{ ft. per min.}$$

(b) The powder smoke is observed to travel 149 × 3 = 447 ft. in (2 × 60) + 17 = 137 sec., or $\frac{447}{137} \times 60 = 195.75$ ft. per min. The average velocity of the air current, however, is less than the observed velocity of the smoke, and may be assumed, with fairly close approximation, to be 0.8 of this velocity. Or, in this case, the average velocity of the air is 195.75 × 0.8 = 156.6 ft. per min., the area of the airway 10 × 12 = 120 sq.ft., and the quantity of air passing is then

$$q = av = 120 \times 156.6$$
$$= \text{say } 18,800 \textit{ cu.ft. per min.}$$

(c) The sectional area of this airway is 6 × 7 = 42 sq.ft. Assuming that the reading of the instrument represents more or less accurately the average velocity of the air current,, the quantity of air passing in this airway is

$$q = av = 42 \times 75$$
$$= 3150 \textit{ cu.ft. per min.}$$

Fireboss Examination

Ques.—If an explosion should occur in a safety lamp in use, what should be done?

Ans.—Assuming that the explosion within the lamp chimney or combustion chamber was light and did not force the flame through the gauze, the lamp should be lowered slowly and carefully withdrawn from the gas. This is a most critical moment and requires the utmost self-possession on the part of the one holding the lamp.

Explosion of gas in a safety lamp usually occurs as a series of small explosions following each other in quick succession. Often little balloons of flame appear and explode with a light pop. The phenomenon indicates a danerous approach to a highly explosive atmosphere. It may be that a more violent explosion in the lamp is only prevented by the extinctive gases (burnt air) confined in the top of the lamp and more or less permeating the air in the combustion chamber. In withdrawing a lamp from a body of sharp gas, the fresh air entering the lamp will often produce a highly explosive mixture within and greatly increase the danger. Under these conditions extreme caution is required to avoid trouble.

Ques.—What are the causes of sudden outbursts of gas in coal mines; and what, in your opinion, should be done to prevent accidents resulting from the same?

Ans.—Sudden outbursts of gas are the result of the gradual weakening of the strata in which the gases are confined under pressure, owing to the extraction of the coal. The roof action in mines, following the extraction of large areas of coal, often results in the formation of vacuous spaces or voids in the strata, and these become filled with gas under great pressure. The gas works forward toward the openings as the strata are disturbed, often producing ominous noises, "bumps" and "poundings." In many cases these noises are followed, after a time, by the bursting out of immense volumes of gas into the mine workings; and frequently the openings are choked with hundreds of tons of coal and slate thrown down by the force of the escaping gas.

In mines where such occurrences are common, every effort should be made to drain the gas from the strata in advance of the workings, by boreholes sunk from the surface or driven in advance of headings; or by driving narrow headings a

distance into the virgin coal and allowing time for the gas to drain off sufficiently to relieve the pressure. All openings should be driven up narrow with wide pillars between them, the principal work depending on drawing back the pillars. The face and ribs of all new work should be well protected by timbering.

Ques.—Are you in favor of mixed lights in mines where explosive gas is generated? Give reasons in full.

Ans.—Mixed lights should never be used. If safeties are required to be used at all in a mine or any portion of a mine, no open lights should be allowed at the same time, in such mine or section. The practice of permitting the use of torches or open lights on entries or gangways, while safety lamps only are to be used at the face, is dangerous; because, at any moment, an accumulation of gas in the waste, or in an idle room, or void place where it has escaped notice may be forced out onto the entry by a fall of roof, or a heavy shot, or by some derangement of the circulation and be ignited by the open lamps.

Ques.—Should a fireboss be under the supervision of the mine boss or superintendent, or should he have complete control over that part of the work that pertains to firebossing?

Ans.—The Indiana mine law, Section 22, makes it "unlawful for any person to serve in the capacity of mine boss, fireboss or hoisting engineer, at any mine, without having . . . . . a certificate of service or competency." It is the evident meaning and intention of the law to place the work of firebossing, in the mine, in charge of a man whose competency to perform that service has been ascertained by a satisfactory examination and is certified by a duly authorized certificate. It would not be logical or in keeping with the spirit of the law to limit the authority of the fireboss in respect to the particular work placed in his charge. In the eyes of the law he is the *competent* person to look after and control whatever pertains to firebossing.

Ques.—Do you approve of the practice of brushing gas from a place with a coat or canvas? State why.

Ans.—The custom of brushing gas is unsafe as a practice, because it can never be known with certainty how much gas may be distributed and thrown into the air. The person brushing out the gas may become enveloped in a dangerous atmosphere, from which he would find it difficult to escape. We may, of course, assume that he has taken the precaution to place his safety lamp where he believes it will cause no trouble, or to extinguish the open light if he has one. Any accumulation of gas in a mine should be handled with caution, and its removal effected by means of temporary brattices, so arranged as to cause the air current to sweep away the gas.

Mine Haulage Question

Mine-haulage Systems Compared

Ques.—Give a brief description of the different systems of haulage used in coal mines; and state the particular advantage or disadvantage of each system.

Ans.—Mine haulage may be divided into two general classes; namely, animal or mule haulage and mechanical haulage, which is again divided into rope and motor haulage. There are three kinds of rope haulage; namely, inclined-plane haulage (which includes both gravity-plane and engine-plane haulage), tail-rope haulage and endless-rope haulage. Motor haulage includes steam, compressed-air and electric motor haulage.

Mule haulage is simple and needs no description. It is best adapted to small mines, not sufficiently developed to install a mechanical system of haulage; and to gathering hauls in larger mines, where the coal is gathered from the different working places and brought by mules to a central station, where trips are made up to be hauled by mechanical means to the shaft or slope bottom.

In gravity-plane haulage, the loaded cars descending the incline by gravity pull the empty cars up the plane by means of a rope that passes over a head-sheave at the top of the plane. The two ends of the rope are attached to the two trips, respectively. Gravity haulage has the advantage that no motive power is required to move the cars.

In engine-plane haulage, a winding engine, located at the top or at the bottom of the plane, hauls the loads up the incline and lowers the empties, by means of a rope attached, in turn, to each trip. Engine-plane haulage is adapted to the haulage of loaded cars up grades that are too steep for mule or motor haulage.

In tail-rope haulage, the loaded cars are hauled in trips, from an inside parting to the shaft or slope bottom, by means of a rope that extends from the winding drum of an engine on the surface, into the mine, and is attached to the front end of the trip. This is the main rope. The tail rope is twice the length of the main rope, and extends from the winding drum of the same haulage engine to the inby end of the parting, where it passes over a tail-sheave and is attached to the rear end of the trip. The tail rope hauls the empty cars into the mine, the cars pulling in the main rope after them. This system is adapted to haulage from several districts and short variable grades that make an endless-rope system impracticable.

The endless-rope system consists of one endless rope running from the double drum or sheaves of the winding engine to the large sheave at the inby end of the parting in the mine and back again to the engine. The rope both here and in the tail-rope system is supported on rollers and small sheaves the entire length of the entry. In this system the cars are attached to the rope at regular intervals by means of a grip or a special automatic clip, the loads being hauled out on one side of the rope and the empties pulled in on the other side continuously. The endless-rope system is well adapted to a long haul on easy grades, a large output and steady producton of coal with little delay.

Motor haulage requires little explanation. Motor cars specially designed for mine work are used instead of mules. Their use is limited to light grades, this limit of gradient being determined practically by the slipping of the motor wheels on the iron rails. In motor-haulage practice, grades exceeding 2.5 per cent. are avoided wherever possible, except for short distances only. It is possible for a motor alone to climb a grade of 8 or even 10 per cent. by sanding the rails; but whenever the grade exceeds, say, 2 or 2.5 per cent., there is too large a proportion of the power of the motor absorbed in its own propulsion, and too little power is effective for hauling the trip.

On level roads a mine motor will generally give a draw-bar pull equal to about $\frac{1}{5}$ of its own weight. Under general conditions in mines, the weight of the loaded trip a motor will pull on a level road is 40 or 50 times the draw-bar pull; or, say 8 or 10 times the weight of the motor car. Grades and curves in the track very much reduce the weight of loaded trip a given motor will haul. The draw-bar pull is reduced 1% for each per cent. of grade, and the live load or weight of loaded trip hauled decreases much more rapidly, being about 50% only, on a 2 per cent. grade.

The speed of hauling in mine-motor practice is commonly estimated, in miles per hour, as about $\frac{1}{5}$ of the diameter of the drive-wheels, in inches, for the full hauling capacity of the motor. For example, a six-ton motor car, with 30-in. drive wheels, may be estimated as capable of hauling, say, 24 loaded mine cars weighing two tons each, at a speed of about 6 miles per hour, under ordinary conditions in mines, on a level road.

Steam locomotives are but little used in mines, because of the gases given off by the furnace in generating the steam. Compressed-air motors have the advantage of greatly assisting the ventilation of the entries by the exhaust air of the engines. This system of haulage requires the installation of a pipe line for conducting the compressed air into the mine, and charging stations and reheaters for heating the air, on long haulages. The pipes are easily broken by roof falls, and the system is not as flexible as electric haulage.

Electric haulage, while introducing the dangers of electricity in the mine, has the advantage of giving a flexible system of haulage capable of reaching all parts of the workings.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

[This department of Coal Age *next week will be devoted entirely to a statement of the views of readers on the subject of sealing off mine fires. A number of letters dealing with the problem, and inspired by our foreword last week, have already been received. We earnestly request every reader who has not yet expressed an opinion to send us a brief statement of his ideas in the matter.* —Ed.]

Gas Locomotives for Mines

The following are some of the results obtained with the "Otto" Internal Combustion mine locomotive, which was referred to in issue No. 7, page 217, of Coal Age, as working at the Barton mines in Nottingham, England.

The length of line inside the mine is about 700 yd. and on the surface about 1½ miles. With the previous horse traction one round trip on the surface line occupied over two hours, including shunting at the wharf, hauling a train of 10 loaded wagons of about 20 tons total gross load. The locomotive makes one trip with the same number of wagons in ¾ of an hour regularly, and in some cases in 35 min. The line is for the greater part level but partly in favor of the loads. The heaviest grades are 0.77% against loads and 4% against empties.

The petrol consumption during 27 workings days was 38 gal. which equals 1.4 gal. per day from 7 a.m., to 5 p.m. During this time 1274 net tons of stone were hauled. This shows that with one gallon of petrol, 33½ net tons were covered; at a tare of 10 cwt. per wagon this represents a total gross load of 47.6 tons, this being over a line of 1½ miles, so that 71.4 ton-miles were covered with one gallon of petrol. The locomotive is fitted with two speed-gears in either direction, i.e., for 3¾ and 7½ miles per hour.

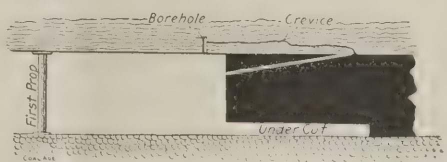
This locomotive has replaced six horses which cost $14.40 per week in fodder alone, while also requiring four boys. The locomotive only requires one driver and one boy for shutting the gates, when crossing the roads. The petrol consumption per week of about 8½ gal. at 16c. exclusive of rebate, amounts to about $1.34 per week.

Thus the great economy of petrol locomotives over horse-haulage is shown by these figures. The driving is extremely simple, one of the miners being appointed to do this. The starting of the locomotive is a matter of minutes, so that during long intervals the engine can be stopped to save petrol.

English Engineer.
Liverpool, England.

Preservation of Draw-Slate

It has occurred to me that as the draw-slate is often loosened by the gases resulting from coal shots, it might be well to drill a few small holes along the face as near the coal as possible, so that the gas might have an opportunity to escape before the center of the open space between the first post and the coal face is reached.



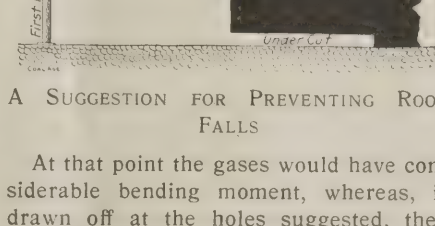
A Suggestion for Preventing Roof Falls

At that point the gases would have considerable bending moment, whereas, if drawn off at the holes suggested, they would have no opportunity to spring the roof. I understand that in some places this scheme is adopted to prevent the fire-damp in the slate from breaking it down.

Chicago, Ill. D. Orson.

Powder in Mines

The accompanying sketch illustrates the working faces of a pair of entries where two miners are at work. *A* and *B* are two crosscuts. *B* is open for ventilation, while *A* is closed with a brattice; two tool boxes are located on both sides of the brattice. Does the law allow each



Location of Tool Boxes

miner to have a keg of powder in the mine? Article XII, rule 26, of the mining laws, relating to the quantity of powder that each miner is allowed to have, says: "Gunpowder or any other explosive shall not be stored in a mine, and a workman shall not have at any one time in any one place more than one keg or box containing 25 lb., unless more is necessary for a person to accomplish one day's work."

According to the law each miner is allowed to store 25 lb. of explosive, and if two miners are permitted to arrange their storing boxes as shown on the sketch, then there would be two kegs or boxes of explosives in one place, while, according to law, there should be only one box or keg in any one place. Each miner should be allowed to store only a half of a keg, or 12½ lb. each.

Now, supposing that a new room is to be started along the gangway, as at *Y*, shown by the dotted lines, there is a possibility of adding another tool box to the crosscut *A*, which already contains two; the new location is to be at *X*. Since each miner is permitted to store 25 lb. of powder, the maximum quantity of 75 lb. of explosive may be stored in one crosscut. In the same way the number of tool boxes can be increased until there are many more in the croscut. Does the law intend to allow each miner to have 25 lb. of explosive stored irrespective of the proximity of other miners' store boxes, or is one crosscut to be occupied by only one miner? At any rate the law is ambiguous, for, judged by common-sense rules, there should be only one tool box in any one crosscut.

Pittston, Penn.

To Avoid Gas Explosions in Mines

I have had 38 years' practical experience in coal mining, doing every kind of work in and about the mines, and I have been watching closely for some time past the mater of gas explosions. It seems to me that with proper care and due regard to the removal of gas, such explosions can be prevented. I have never yet seen the mine that was properly equipped for taking care of the gas the mine produces. If explosions are to be prevented, the mine must be prepared to take care of the gas that is generated just as it is prepared to take care of the coal mined. I will say in regard to the system of ventilation, whether the air is split or not, this alone will not overcome the gas and prevent dangerous accumulations at the working face.

New Philadelphia, Ohio. J. F. H.

[Our correspondent might have suggested just what measures and precautions he considers are essential in the operation of a coal mine, in order that explosions of gas may be avoided.—Editor.]

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Co-operation in Coal Mining Communities

By Charles L. Fay*

In the average large coal-mining community, there are three factors which operate as determining forces in its economic problems.

First. That part of society composed of citizens related to business and professional enterprises outside the coal company interests.

Second. The miners.

Third. The coal company (which is personified in the men holding positions from superintendent to president.)

The selfish attitude of each factor and the consequent lack of vital coöperation prevents the development of a society unit and results in antagonisms. These ill-advised and self-constituted groups make pretensions occasionally, of recognizing a common community interest, but continue, however, to be unduly critical and make of every circumstance a bone of contention about which to quarrel. In all this, a pettiness is oftentimes manifested that is ridiculous, particularly when the largeness of each of the three factors is considered.

The Officious Public

To illustrate my point: the business community decides to promote a welfare movement. It is pointed out that the movement will not only benefit the business community, but the employees of the coal company as well. To qualify the position, it is stated that the movement will benefit the employees by providing a medium and means of self-help that will aid in personal advancement and contribute to their social well-being; also that as the employees are "lifted" in moral standard and vocational efficiency, the company will secure more competent and thrifty workmen, which is of business value to the company.

Consequently factor No. 1 argues with enthusiasm that factor No. 2 should contribute each year the equivalent of at least a day's wages as a nominal share of the necessary support, and that factor No. 3, being the great industrial and financial enterprise of the community and the largest single reaper of benefits, should be the largest single benefactor; but as the movement was originated by factor No. 1 and as factor No. 1 is well fitted to direct its activities, etc., why, of course, while each factor must be represented in the management, factor No. 1 will (with due show of patronage) control the work in hand. The basis of the virtuous proposition presented by factor No. 1, is selfishness, which expresses itself through a generous impulse made negative by a spirit of patronage and condescension.

The Captain of Industry

Reverse the order. Factor No. 3 conceives, from some source of inspiration, an idea that if put in force in the community should operate upon the employees in a manner to benefit the company by tending to regulate the habits of the workmen, and present an opportunity for self help that naturally would lead to more efficient service. Factor No. 3, cognizant of the prejudices of factors Nos. 1 and 2 attempts to so initiate the movement as to throw responsibility upon factor No. 2, but retain the dominating power in the hands of factor No. 3. If factor No. 1 is brought into the matter at all, it is in a nominal way for which factor No. 1 must pay the price, both in substantial support and good will, selfishness being the motive, veneered by virtuous utterance, with the inevitable result that the social unbalance is further developed.

The Suspicious Working Man

Factor No. 2 in the community life is between the "Devil and the deep sea"—needing the constructive and unselfish coöperation of both factors 1 and 3 and yet segregated by both—finally becomes stubborn, suspicious and somewhat hopeless. Factor No. 2 accepts selfishness as the basis of its own struggle for self-preservation and considers coöperation outside its own class as mockery and a sop.

Now, at the dividing lines between the three social factors, and on each side of the lines, are those who possess the neighborly instinct, have some consciousness of brotherhood, a more or less unselfish conception of their own needs and the needs of others. They are glad to help and be helped. It is this advanced group that makes possible some semblance, at least, of a society balance and prevents absolute anarchy.

The Triangle of Forces

The personality of a mining community, such as indicated, must necessarily be negative. What possibilities for genuine, unselfish coöperation in such communities! How ludicrous and wasteful the selfish pull-hauling methods that exist. Yet of the existence of such a discordance, the community may be sublimely unconscious. The loss through lack of sane coöperation is manifested not only in the matter of the social unbalance of the mining communities, but between employer and employees in the much advertised "fight" between capital and labor.

For labor to organize to better the lives and living conditions of working men and to aid each other in becoming more efficient workmen and more capable and intelligent citizens is commendable. Such organization is productive of good and is respected; but to organize primarily to "fight" presumes the objective to be war not peace—destruction not construction—segregation not coöperation. Such organization produces a Napoleonic army in which the leaders are, too often, autocratic officers dominated by biased conviction or overwhelming ambition for leadership and preferment. They sacrifice the rank and file of the workmen to an organization servitude in order to hold intact their autocratic society of professional office holders. The leader with larger vision and nobler purpose is whipped into line or thrown in the "gob."

Finding Only What Is Sought

On the other hand, for capital to organize—well, that is illegal! Nevertheless, for capital to attempt to correlate its forces so as to conserve the best interests of the community the employees and capital, is both desirable and laudable, but when capital employs its superior sagacity in a careful effort to entrench itself for a constant and increasing warfare of absorption and control, setting up the principle of "subdue" or "fight," it then is presuming strife and antagonism and not coöperation.

There are radicals on both sides who cannot comprehend, will not comprehend or for personal venom or advantages do not care to comprehend the loss sustained by society and industry as a direct result of ignoring fair and reasonable coöperation. Just as the citizens not related to the companies and outside the ranks of the employees are a factor in the local community, so is the general public a factor when in a larger sense capital and labor are under con-

*Mining secretary, Pennsylvania State Y. M. C. A., Wilkes-Barre, Penn.

sideration; and while the general public or "third party" suffers from the results of lack of coöperation between capital and labor the "public" is too often, "counted out" as far as rights are concerned.

THE PUBLIC'S EVER-READY REPROACHES

Then again, in times of open strife the public, too often, becomes obsessed by a sentimental bias to one side or the other and feeds the fires of prejudice, further hindering the spirit of coöperation even though by this means the contending forces may be brought, for the time being, to rest on their arms.

Now, there are many on both sides of the ever present capital and labor problem who are doing all in their power to better conditions, to develop the spirit of coöperation and to recognize in due measure the rights of persons and the rights of property. The efforts of such leaders are the sunlight flashes of the dawn of a better day. The sun of coöperation is appearing. Selfishness will be displaced by the spirit of unselfishness. There will be "a new heaven and a new earth."

The battle, however, continues. The basis still is selfishness and the presumption is war. Only as the possibilities in coöperation penetrate the consciousness of the rank and file, will destructive leadership be supplanted, and the day of a better peace actually dawn. What an age of privilege in which to live!

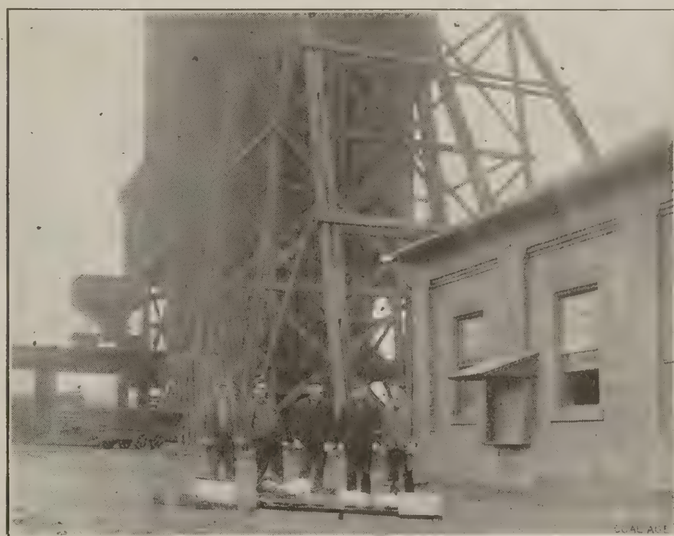
Every thinking man of courage, common sense and character may have a part in developing that consciousness in the minds of the "rank and file" that will make for better conditions and better society. But the road leads not along the way tabbed "political socialism."

First Aid at Frick Plants

BY M. J. SHIELDS*

As the field representative of the first-aid department of the American Red Cross, I undertook the organization and training of first aid corps for the H. C. Frick Coke Co., on Sept. 25, 1911, on which date a meeting was held with all the superintendents present and General Manager Clingerman presiding, at which conference the different coke plants and mines were grouped in five divisions, namely; Baggaley, Mount Pleasant, Connellsville, Uniontown and Brownsville. The superintendents were instructed to select one man out of about every fifty employees to take the training. The selection was made from mine foremen, fire- rib- and coke-bosses, electricians, motormen, hoisting engineers, miners and some outside employees. The company had a number of trained helmet and rescue men, and also quite a number of employees who had received first aid training, and they were afterwards added. So the number of men who actually attended the meetings comprised one in every thirty employees, or a total of nearly eight hundred men. A course of seven lectures was given weekly, with an intermission of two weeks, thus extending over a period of two months. The meetings were held in halls, centrally located, and all during the day time and on idle days, except in the Baggaley division. All the men instructed were supplied with the American Red Cross abridged first-aid textbook, the foreigners receiving Polish, Slavish and Italian editions, and the course of instruction pursued is the one found on page 164 in that book, namely: (1) Structure and mechanism of the body and the materials for first aid; (2) general directions for rendering first aid, study of fractures, dislocations, strains, bruises and shocks; (3) wounds, burns, scalds, and electric burns; (4) unconscious conditions, the handling and carrying of the injured; (5) special and mine injuries; (6) sanitary matters and the prevention of diseases; (7) a general review in the form of first aid contests. These lectures lasted about half an hour and then the men were given triangles, roller bandages, splints, and other first aid materials, and a practice drill took place which lasted from an hour to an hour and a half. This drill was superintended by the Company physicians and myself, and the finished work examined and criticised, and the meetings closed by free discussion of the subjects gone over in the lecture. The lecture, drill and discussion together made the total time devoted to each meeting two hours. The course ended on Nov. 25, by a series of contests in each division and the following are the names of the winners in the team obtaining first place, and the percentages scored by all the teams.

DAVIDSON MINE SQUAD



FIRST-AID AND HELMET MEN

Brownsville Division.—Edenborn mine 100%—James Curry (captain), Cyrus Flesher, John Mullen (subject), Thomas Daugherty, Austin Kane, Thomas Laughran. Leckrone mine 99.%. Lambert mine 99.5%.

Uniontown Division. — Continental No. 2 mine 100%—John Tupper (captain), George Haines (subject), Wm. Cosgrove, Gideon Pike, Huston Doyle, John Bloom. Phillips mine 99.2%. Yorkrun mine 97.5%.

Mt. Pleasant Division. — Marguerite mine 100%.—A. S. Snyder (captain), Michael Kavanshansky (subject), Thos. McDermott, A. M. Weaver, Steve Susa, Harry Hudson. Standard mine 98.3%. United mine 98%.

Connellsville Division.—Davidson mine

*First Lieutenant, Medical Relief Corps, U. S. Army, Scranton, Penn.

99.1%—Max Reidman (captain), Frank Bell, John J. Malloy, Joseph Morgan, James Yocum, George Rushnock (subject). Leisenring No. 3 mine 98.3%. Everson car shops 97.5%.

Baggaley Division—Baggaley mine 94%. John McKenna (captain), Frank Bolton, George Hoke, R. H. Barry, Harry Blystone (subject), Christ Hoke. Whitney mine 93%. Dorothy mine 91%.

The first aid department of the American Red Cross Society gave bronze medals as first prizes and certificates of merit for the second and third prizes. As contests are the next best proof to real accidents of first aid efficiency, these competitions showed some remarkable results. They proved that the men had taken a deep interest in the work and demonstrated a capacity to deal with any and all kinds of accidents in an intelligent way and I might add that contests are not only educational, but school the first aid man to be cool and calm in a real accident and remember what he knows. These contests were judged by two physicians and one practical mining man.

A table of specific discounts was prepared by the judges and read out prior to the beginning of the contest. It was as follows:

DISCOUNT FOR FIRST AID CONTESTS

	%
For loose or granny knot	5
For a loose bandage	5
For a loose splint	5
For faulty artificial respiration	5
For not stopping bleeding	10
For not taking care of shock	10
For not doing the most important thing first	5
For slowness in work	5
For captain's failure to command men properly	5
For awkward handling of patient or stretcher	5
For failure to be aseptic	5
For failure to entirely cover the wound	5
For lack of neatness	5

SAFETY THE FIRST CONSIDERATION

Each team consisted of six men, captain, subject and four assistants, and the squads were started out with a credit of one hundred per cent. and discounted from the above table. There were fifty-four teams entered and the halls where the contests were held were crowded with spectators. In this work I received the hearty co-operation of Mr. Clingerman, the general manager, and the other officials, specially C. L. Albright, secretary of the Beneficial Association. The organization and training of this splendid body of first aid men rounds out the motto and policy that President Thomas J. Lynch has adopted and carried out: "Safety the first consideration," a motto which he has striven to embody, not alone in first aid, but also in manifold schemes for accident prevention.

DAVIDSON MINE OF THE H. C. FRICK COKE COMPANY

First Aid Hints

All large mines should be equipped with four rescue corps, two inside and two outside. Each crew should consist of no less than six men, trained, not only in the use of apparatus, but also to implicit obedience to the commands of their leader. Such crews should receive instructions and training once a week.

When working in unbreathable gas see that all members of a rescue party keep close together and that every precaution is taken for their safety. Establish a relief station and a relief crew at the end of the breathable air. Patrol all doors and brattices leading to this station as a protection to the waiting relief crew. When working in thick smoke see that each rescue party retains the end of a rope that is stretched to fresh air.

When an accident has occurred remove the patient to a quiet place, taking him to the hospital room at once if his condition permits. Never carry a seriously injured patient to the engine room, as the jar of the engines is often the cause of intense agony to his shattered nerves and bones. The noise of the moving machinery also causes acute mental distress to a suffering man. Handle the patient calmly, gently, and without the appearance of nervous haste. If the head is injured it should be elevated above the body, otherwise keep the whole body on a level unless the patient is faint, in which case raise the feet or lower the head. Injured legs or arms may be benefited by being raised slightly from the level of the body. A gentle pulling of the leg of the patient not only aids, but gives him a marked sense of relief. The leg muscles tend to contract and draw a broken limb further out of line. This is corrected by gentle traction.

The most comfortable position is usually on the back with the limbs stretched out. Loosen all tight bands, cut all clothing covering the wound, but remove only just enough to allow of a thorough inspection and dressing of the wound. Dress the wound as quickly as possible to prevent infection. Do not permit your hands to come in contact with the wound unless they are aseptic. All severe bleeding should be stopped before the final dressing takes place. If the patient is unconscious, watch him with the utmost attention; if he shows signs of vomiting, place him upon his side, with the head lowered, so that the vomit may not pass into the lungs. In case of burns the wetting of the clothing with a solution of luke-warm water and baking soda will tend to relieve the pain. After the wound is dressed, let the patient rest quietly a short time before he is removed.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Coal and the Money Trust

An interesting feature in connection with the demand for a money trust inquiry is found in the fact that Mr. Lindbergh, of Minnesota, who is demanding the investigation, is apparently disposed to charge that what he terms the "money trust" is operating in connection with the coal industry. Mr. Lindbergh has submitted to the Committee on Rules, which is considering this matter, together with other data, the following statement:

"These subsidiary railway corporations, outside of the value of the express companies as stock-holding concerns, are small affairs. Their total capitalization is not over $259,000,000, with a market value of under $350,000,000. The anthracite-coal monopoly created by Morgan and Baker through the railroads is of more consequence.

"About $160,000,000 worth of anthracite coal is produced annually in the United States. All this comes from a small area of Pennsylvania. The railroads have been for 40 years buying control of these anthracite-coal lands. The first important work of Morgan as a maker of monopoly was the eliminating of competition by buying control of a competing railroad line for the New York Central. The second was an attempt to create an anthracite-coal monopoly through railroad combination. He worked at this for 20 years, and George F. Baker nearly as long, and 10 years ago the monopoly was formed. The roads that hold it are now all in the control of the seven men. These roads now own lands containing about 95 per cent. of the anthracite coal in the United States. They produce only 82 per cent. It is their policy to let the independent operators work out their deposits. This will give them in the future a still greater control of this mineral.

"It has been difficult to create any monopoly of the bituminous coal of the country; it covers so great an area. But this, like anthracite, is naturally controlled by the railroads which take it to the consumer; and there are many effective local monopolies. Morgan has been active in creating these in connection with Eastern roads. West of the Mississippi a great share of the usable coal is controlled either by the Union Pacific, the Gould system, or the Hill Lines."

This is one of the grounds upon which Mr. Lindbergh demands that investigation shall be undertaken by the committee; it being a fundamental feature of his ideas that there exists an improper relation of some kind between the banks, which, he alleges, control the money of the country, and the persons who are engaged in the production of various staple articles of which coal is one. It has not yet been decided whether to undertake the investigation or not, but the chances still favor the probability that the investigation will be begun on this or some other basis.

Progress in Pittsburg-Lake Freight-Rate Case

The Interstate Commerce Commission has resumed work on the so called Boileau case which involves the question of the relative rates between the Pittsburg district and the lake ports on the one hand and the West Virginia mines and the lake ports on the other. The discussion has now largely degenerated into a battle between accountants who are endeavoring to show what proportion of the revenues of the various roads are actually derived from coal and what proportion of the outlay is caused by the transportation of coal, this for the purpose of determining a "reasonable rate."

The Works, Coal-Mines Bill

A bill to provide for the inspection and regulation of coal mines has been introduced by Senator Works, of California. This authorizes the Secretary of the Interior to make and enforce such rules and regulations as may be necessary for the control of coal mines operating in the territories or producing coal in any state for transportation to any other state, thus taking up the old idea that the Federal government may supervise the conditions under which commodities entering into interstate trade are produced.

Section 3 of the bill provides for coöperation with state mining bureaus or commissions, and Section 4 authorizes the Secretary to go into any mine that he may wish for the purpose of ascertaining what changes of management are needed. The section continues as follows:

"That when the said Secretary shall make any order respecting the management or operation of any mine or the use or disuse of any device, apparatus, or appliance in the operation thereof, the owner or lessee of such mine shall comply with such order within a time to be fixed by said Secretary. If such owner or lessee of any such mine, or any officer or agent of such owner or lessee, shall fail or refuse to comply with any such order he shall be guilty of a misdemeanor and be fined not less than one hundred dollars nor more than five thousand dollars, to which may be added imprisonment for not exceeding six months, and each day that he shall so fail or refuse shall be a separate offense, and the said Secretary may, in his discretion, require that such mine be closed and not operated until such order is complied with, and may enforce such requirement by proper legal proceeding if not complied with."

Alabama

Birmingham—Fire, Jan. 7, at the Carbon Hill mines of the Galloway Coal & Coke Co., in Walker County, destroyed the engine house and damaged a large amount of machinery. It was with difficulty prevented from spreading to other buildings on the property. The loss is estimated at $50,000.

The Tennessee Coal, Iron & R.R. Co. has started work on the construction of 150 miner's houses at its No. 12 mines, Ensley, Ala. A new town is also being built at Edgewater near the No. 13 mines.

Colorado

Fort Lupton—Following the arrest of five union miners at the Alpha coal mines, Jan. 7, charged with riot and unlawful assemblage, all troubles ceased at the mine, and a small force of non-union miners began work the next day.

Trinidad—The Wootton Land & Fuel Co., controlled by J. P. Morgan, B. F. Cheney and a syndicate of Boston capitalists, is now operating two mines on the historic Wootton estate. The new tipple has just been completed and more than $100,000 has recently been spent in development work. Colonel J. A. Owenby, formerly of Boulder, is in charge of the properties.

Illinois

Harrisburg—The O'Gara Coal Co., which at present has a group of 17 coal mines in this vicinity, is preparing to sink two new shafts east of Harrisburg, where the company has held options for some time on the coal under 3000 acres of land. The coal is practically the same as found in other sections of this and surrounding counties.

Springfield—The Tuxhorn Coal Co. has resumed work at its mine which

has been closed down since Oct. 1, owing to a lack of orders. The mine has opened with the full force of 175 men and the prospects are good for a large business.

Canton—Owing to the falling of doors that govern the passage of air from the fan at the mine of the National Coal Co., near Middle Grove, between 15 and 20 miners were affected by lack of air, one morning recently, and operations were suspended for the remainder of the day. A similar accident took place at the No. 2 Blackhawk mine, Farmington, where 40 men were taken out from the workings before being seriously affected.

Streator—The local mine of the Harrison Coal Co. was closed down recently for a time on account of water which had seeped in from the abandoned workings at No. 4 shaft about a mile distant.

Chicago—At a meeting of representatives of the coal operators of Illinois, Indiana, Michigan, Wyoming, Montana, Iowa, Kansas, Missouri and Oklahoma, an organization known as the American Federation of Coal Operators was effected, Jan. 16, for the purpose of bringing about a peaceful solution of labor disputes. H. N. Taylor was chosen president, C. S. Keith vice-president, and Charles L. Scroggs secretary and treasurer.

During the recent cold weather the coal supply in Chicago became seriously depleted, on account of the difficulty in moving freight and operating the mines. Severe coal famines were also reported from many points in central Illinois.

Belleville—The Illinois mine-rescue car, after being stationed at Collinsville for several weeks, came here, Jan. 14, for a five or six weeks' stay.

Indiana

Indianapolis—Practically every loaded car of coal has been sent forward from the Indiana mines and empty cars sent in. Probably every mine in the state was in operation Monday, Jan. 22, for the first time in two years. Thanks are due to the good work of the railroad commission, the members of which went into the coal-distributing yards and ordered the companies to move the coal. If the mild weather continues there will be a rush to store coal by large consumers in preparation for a suspension or strike after Apr. 1. The belief persists that there will be trouble between the miners and operators.

Clinton—The Oak Hill Coal & Mining Co. has been sold to J. K. Dering, and the property transferred. Five mines in the Clinton field and about 3600 acres of coal lands are included in the deal which is said to involve $1,000,000, although the sum was not made public. The local management will not be changed except for Edward Shirkie's retirement, and the mines will continue active.

Sullivan—The last of the $100,000 which was the price paid by the Jackson Hill Coal Mining & Transport Co. for 2000 acres of coal land in Haddon township near Paxton, was paid over recently, thus closing what up to that time was the biggest coal deal ever put through in Sullivan County. Since the deal was closed last July, a large number of surveys have been made in the vicinity of Paxton, and it is said steps will be taken in the near future to sink mines.

John P. White, of Oskaloosa, Iowa, was reëlected president of the United Mine Workers by a majority of 45,424 over his oponent, Thomas L. Lewis, of Bridgeport, Ohio, according to the report of the tellers made to the convention, Jan. 18.

The wage-scale committee of the United Mine Workers of America organized Jan. 18 with J. H. Walker, of the Illinois district, as chairman. The scale committee will demand an increase in the mining rate for both bituminous and anthracite fields. Some of the members say they favor an increase of 10c. a ton, while others have indicated a preference for a 5c. advance, with a run-of-mine basis.

Iowa

Des Moines—Serious coal shortage was recently reported from practically all parts of the state; in some places it amounted to a famine. The local Commercial Club was inclined to blame the Rock Island R.R. Co. for much of the suffering in Des Moines.

Kentucky

Central City—Five men were killed as a result of an explosion in a mine of the Central City Coal & Iron Co. about 5 o'clock in the morning of Jan. 17. Four bodies have been removed. The cause is unknown. The mine is not badly damaged. Two hundred men usually are at work in the mine, but the explosion came soon after the day shift had come out and before the night men had gone down.

Louisville—The mine owners of Kentucky, carrying out a plan which had been under consideration for some time, have organized the Mine Owners' Association of Kentucky, the announced object being to promote the interests of the mining industry. The association was formed at a meeting held at Louisville. Officers were chosen and authorized to take immediate steps toward affiliating the body with the American Mining Congress.

Whitesburg—The new city of Jenkins in the Elkhorn coal field has been incorporated.

The Louisville & Eastern is to be extended from Torrent to Jackson, by way of Devil's Creek. In order to hasten this extension, owners of property along the proposed route are offering every encouragement possible in the way of reasonable charges for rights of way.

Middlesboro—The Gibson-Carr company, of Middlesboro, will be ready to ship coal by the first of February from its new mine, opened on Tye Fork of Brush Creek, Knox County. The Sneed & Meguire Coal Co., of Louisville, recently leased 10,000 acres on Colver Creek, and the Louisville & Nashville is building a branch from the terminus of the Black Mountain & Wasioto road, 20 miles north of Harlan, to the Sneed & Meguire property.

Minnesota

Albert Lea—Specimens of lignite coal, found in a trench in Mansfield, have been received here. The coal seems to be a good quality of lignite, and, as it was found close to the surface, it is presumed larger quantities can be found more deeply embedded. Some gas and indications of oil also are said to exist in the locality of the coal find. It is not probable any active investigations will be made until spring.

Missouri

Windsor—Two men were entombed and 300 had a narrow escape in the afternoon of Jan. 13, when an explosion wrecked the mine of the Bowen Coal Co., near Windsor. The day shift, comprising 300 miners, had been out of the workings only 30 min. when the explosion occurred. The cages were thrown off the guides and jammed in the shaft by the force of the blast. Rescue parties were immediately organized and through another shaft entered the west part of the mine, but no trace of the shotfirers was found. Efforts to enter the east part failed because of the smoke and heat. There is no gas in the mine, and it is believed dust caused the explosion. As soon as the explosion occurred, the fans were reversed, and an effort made to draw the gases from the mine, but this failed, because the brattices that direct the air currents were shattered by the explosion. The mine has been considered one of the safest and best equipped in the state.

Ohio

Ashtabula—This city is experiencing a coal famine. Dealers are entirely sold out, but shipments of coal are expected daily.

Gallipolis—One hundred and fifty coal barges are held up at the mouth of the Great Kanawha River in a dangerous freeze-up. Rivermen fear considerable damage when the ice breaks up.

Steubenville—A heavy ice gorge at Cables Eddy, on the Ohio River, three miles above this place, broke Jan. 18, and carried away a towboat, 18 empty coal

barges and a wharfboat. Three of the barges were sunk.

Youngstown—A number of the merchant furnaces, which have large ore mines in the Lake Superior district, and coal mines in the Pennsylvania and West Virginia districts, have signified their intention of entering a steel merger, which, it is reported, will take place here soon.

Martins Ferry—Three hundred miners, employed by the Moore's Run Coal Co. in its operations west of this city, are on strike because of a claim that they are not getting full weight for coal mined. The men object to the "dumper" in use at the mine.

Pennsylvania

Bituminous

Washington—The Vesta No. 5 mine, at Fredericktown, idle for more than a year, has resumed operations. A large new tipple has been built and much modern machinery installed. Only about 225 men are to be employed; later a much larger force will be taken on.

Charleroi—It was reported here recently, on excellent authority, that negotiations have about been completed by which the Diamond Coal & Coke Co. will take over the coal holdings at Charleroi of the Pittsburg Plate Glass Co., known as the Charleroi Coal works. Twelve hundred acres of virgin coal land are included in the reported transaction. The purchase price is in the neighborhood of $1,250,000.

Pittsburg—The mines of the Pittsburg-Buffalo Co., at Marianna, Penn., have resumed operations, and immediate employment will be given to 500 additional men. The 200 coke ovens operated by the company t Marianna will be lighted and employment for more than 1100 men will be afforded next month. The mines now have a daily output of about 3000 tons, and this will be increased to 4000 tons next month.

The coal operators of western Pennsylvania, Ohio and Indiana decided at a joint meeting held here, Jan. 18, to accept the invitation of the miners to meet in Indianapolis, on Jan. 25, to negotiate a wage scale.

Colver—The construction work on the new tipple which the Link-Belt Co. has recently designed for the Ebensburg Coal Co.'s mine here, is well under way. This tipple will be one of the largest and most uptodate installations in this vicinity, being equipped with loaded and empty car hauls, shaking screens, rock conveyors, etc.

Anthracite

It has been announced that the Monongahela Coal & Coke Co. will this spring build a block of 23 houses near California for the employees of the Crescent mine.

Monongahela—The Dunkirk mine, of the Pittsburg & Westmoreland Coal Co., resumed operation recently, after being shut down for a month. Over 250 men are employed.

The Webster mine of the Henderson Coal Co. will be ready to run the latter part of this month.

Pittston—Firemen, ashmen and others employed about the Clarence colliery of the Hillside Coal & Iron Co., had a miraculous escape from injury or death, Jan. 12, when one of a set of five boilers at the colliery exploded, completely wrecking the fireroom and sending portions of the boiler flying for a distance of a hundred yards. At the time of the explosion the ashmen and firemen happened to be outside the fireroom.

Wilkes-Barre—Cold spells during December had the effect of keeping up the demand for anthracite coal and the price per ton averaged $4.89 during that month. This gives the mine workers an increase of 7 per cent. over the regular rate of wages. It will be applied on the January earnings. For the two months previous the sliding scale was 8 per cent., and the prospect is that January will witness another record-breaking demand for coal.

It is rumored here that the coal operators have decided to grant a general increase of 10 per cent. in wages to the miners at the expiration of their contract, on March 31. This will be the only concession the operators will make, but it is regarded as a stroke which will prevent any effort to strike. The offer will be made to the miners as soon as their demands are presented.

Shenandoah—Six miners were seriously injured, Jan. 12, when a box of dynamite caps exploded at the Knickerbocker colliery.

Washington

Ellensburg—What is believed to be the most important coal strike yet made in this state was recently reported here. Nine hundred feet of gangway have disclosed a seam from 14 to 20 ft. thick and a borehole 840 ft. deep shows nine distinct veins of good coal. The coal is apparently an excellent grade of bituminous and suitable for coking. Capital has been raised for development and a tipple will be built at an early date.

West Virginia

Parkersburg—A deal has been closed whereby the Spruce Park Coal Co. becomes owner of 3400 acres of coal land in Logan and Lincoln Counties, for a consideration of $250,000. C. H. Blair, of Philadelphia, president of the company, was in Parkersburg, to close the deal, and said the company already has made arrangements for leasing a large part of the land and will itself operate the remainder of the property.

Welch—The United States Coal & Coke Co., operating at Gary, McDowell County, lighted 1100 coke ovens recently, giving employment to a number of men at the ovens, and necessitating the employment of many more men in the mines, in order to provide the needed increase in output.

Keyser—The case of the Central R.R. of New Jersey against the Davis Coal & Coke Co., claiming $2200 demurrage on cars of coal shipped over its lines to tidewater after transfer from the Western Maryland R.R., was heard here, Jan. 19, and a settlement of $1925 agreed upon.

Fairmont—Full operations are being resumed in the Annabelle mines of the Pittsburg-Buffalo Co. at Annabelle, Marion County, and the Dorothy mine in Raleigh County will be operated to its full capacity. Two hundred men will be needed next month at each of the two mines. Contracts have been closed for the entire output of the coke ovens of the company during the present year. At Annabelle, 1000 tons a day is being mined. This will be doubled in February, and in a few months it will run at its capacity of 6000 tons a day. Dorothy mine will turn out 4500 tons daily within a few months.

Wyoming

Kemmerer—Five men were killed and 18 injured, Jan. 20, by a dust explosion in mine No. 4 of the Kemmerer Coal Co. The explosion occurred in what is known as the second north entry, 100 ft. from the main slope and 1000 ft. from the surface. The force of the explosion was confined and only those working in the immediate vicinity were injured. Miners in other portions of the mine made their way to the surface uninjured. The fans remained in operation and the afterdamp soon was cleared from the entries.

Canada

Nova Scotia—The Dominion Coal Co., one of the subsidiaries of the Dominion Steel Corporation, will soon have five new collieries in the Lingan district, the best coal section of Nova Scotia; two more in Morien and three others at Springhill, making 10 collieries added to 10 old ones. Expenditures for these and other additions will aggregate $5,475,000, of which $3,250,000 is still to be spent. Production this year is expected to total 4,500,000 tons of coal.

Alberta—A new discovery of coking coal has been made at Cardston, near Lethbridge, and a company has been organized under the name of the Cardston Coal & Coke Co., with a capital stock of $150,000, to develop the property. The company has secured leases and will commence work at once.

Personals

Dr. R. N. Mackey, formerly of the Moses Taylor Hospital, has accepted a position with the Red Cross Society and will be detailed in the near future for mining work, a special car being provided for his use.

Col. R. A. Phillips, general manager of the coal department of the Lackawanna R.R. Co., has published a book on "How to Prevent Mine Accidents." The book will be distributed to all Lackawanna mines for benefit of the employees.

Charles L. Fay, mining secretary, Pennsylvania State Y. M. C. A., was in Washington last week and secured Dr. A. J. Holmes, Director U. S. Bureau of Mines, as one of the principal speakers at the Y. M. C. A. state convention to be held, Feb. 22-25, at Bradford, Penn.

Earl Bradbury has returned to Rock Springs, Wyo., to assume the duties of assistant chief engineer for the Union Pacific Coal Co., to which position he has just been promoted. Mr. Bradbury has been stationed at Rock Springs at different times during his work with the company, but has recently been stationed at Hanna.

G. A. Burrell, chief chemist of the U. S. Bureau of Mines, Pittsburg, Penn., recently made a trip of inspection through Alabama and Tennessee. At Birmingham, Ala., Mr. Burrell visited the newly equipped state laboratory in company with Chief Mine Inspector Nesbit and made analyses of air from several Alabama mines.

Kuper Hood, well known in middle-west and southern coal circles, has been appointed general manager of the Thacker company, succeeding F. H. Benedict, who will remain with the company in an advisory capacity until April, when he will go to the Pacific Coast to settle permanently. Mr. Hood was formerly assistant manager.

William Griffith, mining engineer, Scranton, Penn., has been appointed one of a committee of five of the American Mining Congress to coöperate with the Secretary of the Interior regarding the most feasible plan for the development of mineral and coal lands in Alaska. Mr. Griffith has been engaged in development work in Alaska for several years.

John P. Walter, who for nine years has been chief engineer for the Pennsylvania Coal & Coke Co., at Cresson, Penn., has resigned and will sever his connection with the company, Apr. 1. Mr. Walter leaves with the best wishes of his associates for his future success and the deserved recognition of his employers of his ability in handling the problems that have confronted the coal company in its many operations.

Obituary

John Farrell, a first-aid man attached to the Bureau of Mines, was killed, Jan. 20, while examining the condition of a gaseous mine, at Cherry Valley, Penn.

John N. Luther, assistant general manager of the Spring Valley Coal Co., died suddenly, Jan. 17, at the Mercy Hospital, in Chicago, following an operation. Mr. Luther had been an official of the coal company nearly 20 years.

William Immenhort, Jr., assistant general manager of the Marmet-Hahn Coal Co., Columbus, Ohio, was drowned recently in the Ohio River. Mr. Immenhort, who was 35 years old and well known to the coal trade, was looking after the company's fleet of barges, which were at the time caught in an ice jam and in some danger of being carried away. He fell from one of the barges and his body was not recovered for several days.

Construction News

Harrisburg, Ill.—The O'Gara Coal Co., which has 17 coal mines in this county, is preparing to sink two new shafts east of Harrisburg, where options are held on coal under 3000 acres of land.

The Saline County Coal Co. is sinking a shaft two miles west of Harrisburg.

Glacier, Wash.—The Washington Anthracite Coal Co. is planning the erection of a tipple and complete surface works to handle the output of their mine here. H. O. Watrous, Glacier, is manager.

Washoe, Mont.—The Montana Coal & Iron Co. is taking bids for sinking a rock slope approximately 315 ft. long and on a 15-deg. pitch, on their property here. E. M. Cortright is engineer and W. W. Worthington, Washoe, is president of the company.

Brownsville, Penn.—George F. Hosack, president of the Cross Creek Coal Co. has awarded the contract for sinking two shafts near Burgettstown, to the Brownsville Engineering Co.; contract price, $90,000. The shafts are to be 270 ft. deep.

Birmingham, Ala.—The Pratt Consolidated Coal Co., of Birmingham, will expend $75,000 for improvements at its Flat Creek mines, the betterments to include a new prison, hospital and other accessories for about 300 convicts.

Charleroi, Penn.—The Monongahela River Consolidated Coal & Coke Co. will build 23 houses at its Crescent mine, California, Penn., and it is understood, will install a 150-hp. steam turbine at the Coal Bluff mine, Gastonville.

Beech, W. Va.—The Spruce Bend Coal Co. has just placed an order with the Link Belt Co., Chicago, for a car-haul and shaking-screen outfit to be furnished and erected complete at their mine.

New Publications

COLORADO SCHOOL OF MINES MAGAZINE FOR JANUARY, 1912. 22 pp., 6¾x10 in., 25c. Colorado School of Mines Alumni Association, Publishers, Golden, Colo.

PRODUCTION OF COAL AND COKE IN CANADA, 1910. By John McLeish, B. A. Bulletin of Department of Mines, Canada. Government Printing Bureau, Ottawa.

This is an advance chapter of the annual report on the mineral production of Canada, 1910, giving statistics of coal and coke production, exports and consumption for the calendar year 1910, and also for the past 30 years. Figures are tabulated and given by districts.

THE USES OF PEAT FOR FUEL AND OTHER PURPOSES. By Charles A. Davis. Bulletin No. 16, Bureau of Mines, 1911. 214 pp., 6x9 in., 1 plate. Free on request.

There are extensive and widely distributed deposits of peat in the United States, but until quite recently its production for fuel on a commercial scale has been accorded but little attention. This bulletin by Mr. Davis is a comprehensive treatise on the subject of peat in general, its formation, composition and uses, and on the origin and characteristics of its several forms. Processes for the preparation and manufacture of peat fuel are reviewed in detail, including such matters as the mechanical equipment of plants, costs, methods of operation and commercial possibilities. These data are necessarily acquired largely from the practice in European countries where the peat industry has reached a comparatively advanced stage of development. The use of peat in connection with gas producers is emphasized as giving particularly gratifying results, and its value as a raw material for other products than fuel is explained at some length by numerous examples. Tabulated analysis are given of samples of peat from practically every known area in the United States.

Trade Publications

General Fire Extinguisher Co., New York. Bulletin, "Grinnell" Automatic Sprinkler. 24 pp., 7¾x10½ in., illustrated.

Ingersoll-Rand Co., New York City. Bulletin, Form 4204, "Arc Valve" Tappet Rock Drills. 16 pp., 6x9 in., illustrated.

The positive quality of the valve movement in this drill renders it peculiarly useful when steam is used and when water of condensation is likely to be encountered. Catalog shows sectional views of drill and also gives list of duplicate parts, together with descriptive table of sizes and capacities.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The return of milder weather has effected a considerable change in market conditions. Transportation, while by no means back to normal, has improved materially; the result is that heavy tonnages are being moved. The mines have increased their output and there is again some evidence of surplus coal.

The movement to Atlantic coast ports has probably suffered the most and there is still a pronounced fuel shortage at these points. The railroads were tied up and water cargoes ice-bound, while the coal was frozen and difficult to handle; however, conditions now are much easier.

In Pittsburg and vicinity, the mines are working better time, and the production is heavy. Railroad service is still in bad shape, but improving, and the market is active, particularly in slack. The cold weather has cleaned up all free coal in Ohio and prices are stronger, especially in the smaller sizes, for which there is a heavy demand; weather conditions also affected transportation, especially on the Ohio River, where heavy losses, due to ice-floes, have been narrowly averted. The customary winter storing of slack, usually effective at this time in West Virginia and Tennessee, has not yet started because of the curtailed production at the mines.

In the Middle West, the situation, as regards supplies, is much improved, and the market is softer. The scarcity of coal, due to poor railroad service, has been relieved, and it is generally believed that continued warm weather will result in a heavy influx of standard sizes. In the West and on the Pacific Coast the trade is quiet and unchanged.

Boston, Mass.

Conditions early in the week bordered on distress for many of the shippers and dealers. Cargoes were ice-bound along the coast, and rivers and inlets ordinarily navigable were impassable. Spot deliveries of bituminous were therefore in demand and as high as $4.35 on cars, Providence, was paid for temporary supply. At Boston, many consignees have been on the ragged edge, but managed to pull through when milder weather let in some delayed arrivals. At the loading piers, dumping is slow because of frozen coal, and the whole market is decidedly irregular.

Water freights are the same as last week, $1@1.10, Hampton Roads to Boston, with premiums of 10@20c. for shoal boats. The rate to Providence is $1, and for New York loading 75c. has been paid. Shippers continue cautious over making charters.

The following are current prices for Pocahontas and New River steam:

Providence, on cars	$4.10@4.35
Boston, on cars	4.20@4.35
Shipments from Hampton Roads, f.o.b.	2.70

New York

The market here during the past week has been extremely active. Owing to the unusually cold weather, railroad transportation has been almost completely tied up for four or five days, with the result that the tonnage on hand at the piers has been gradually reduced. Coal at the piers is in a badly frozen condition so that there has been delays in loading of from three days to a week, which has made it difficult for shippers to satisfy the demands of their customers. This delay in loading at the piers has created a shortage in the supply of loaded coal; consequently water cargoes have commanded a considerable premium over f.o.b. coal, depending upon the urgency of the demand. Some loaded cargoes are reported to have sold as high as $3.40 alongside.

Car supply at the mines has been short all during this extreme weather so that it will be some time before the standing tonnage at New York is again at the normal.

There has been a strong demand for the higher grades of steam coals and all of these are practically out of the market for the present, as the shippers, without exception, have all they can do to take care of contract obligations. West Virginia steam coals f.o.b. New York are quoted from $2.55 to $2.65; ordinary Pennsylvanias $2.65 to $2.75, with the better grades out of the market.

Philadelphia, Penn.

While the weather has moderated considerably in this vicinity compared with the last week or two, the dealers continue to be quite busy in delivering orders. The offices of the local wholesalers are besieged with dealers, begging shipments on their orders for almost every size, particularly stove, chestnut and pea, which are in short supply. The streets, however, are now clear of ice, and the expensive deliveries have been eliminated.

The scarcity of certain sizes has resulted in pinching some of the dealers who have taken contracts at low prices with operators who have not been able to furnish them with the coal and they are compelled to pay considerably higher prices for the size required. One instance is noted of a concern having a contract to supply a hospital with buckwheat at a price of $1.15 at the mines, and it is understood that they were compelled to pay $1.50 at the mines for the coal. A number of instances of this kind occurred, and confirms earlier predictions that there would be a "squeeze" on some sizes before the winter season had passed.

The wholesale market was never better; even egg coal is no longer consigned to the storage yards, but applied on direct orders, and there is delay of two to three days in making shipments at that. Prompt shipment of any size at the present time is not promised, and on stove, chestnut and pea, orders have to take their turn; from one to two weeks elapse before even one car of these sizes will come out. Broken coal demand still exceeds the output, while the stocks of pea and rice have been entirely disposed of, and the production of these sizes is entirely inadequate to supply the market at the present time.

Pittsburg

Bituminous—Mine operations are being conducted to better advantage, as the severest of the cold snap is over. The percentage of operation is higher and coal movement is also much better, so that a fair supply is now being given to consumers. A disposition to stock up against the expected suspension of mining is beginning to be manifested, and the mines will have little difficulty in finding business to work up to the output the weather and shipping facilities will permit, from now to the end of March.

The coal market is steadier, fancy prices being less often paid. We quote: Nut, $1.05@1.10; mine-run, $1.10@1.15; ¾-in., $1.20@1.25; 1¼-in., $1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg.

Connellsville Coke—While there are signs that the movement of coke will loosen up, spot coke continues scarce and is commanding practically as high prices as at any time. In the past week sales of small lots of prompt furnace coke have been made at all the way from $1.85 to

$2, depending upon the exigencies of the case. It now appears as if the higher prices had come to stay, as operators are asking about the same range on contract coke.

The price situation is undoubtedly greatly helped by the prospect that there will be a suspension in the union districts Apr. 1, which would furnish a considerable market for Connellsville coal, the scarcity making up for the fact that Connellsville coal is at a freight disadvantage of 15c. a ton over the Pittsburg district. Operators would rather sell their coal at $1.10, at mine, than accept lower than present prices for coke. We quote: Prompt furnace, $1.85@2; contract furnace, $1.80@1.90; prompt foundry, $2@2.25; contract foundry, $2.10@2.25.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Jan. 13, at 391,432 tons, an increase of 68,000 tons, and shipments at 3620 cars to Pittsburg, 5051 cars to points West and 670 cars to points East, a total of 9341 cars, an increase of 250 cars.

Buffalo, N. Y.

There is a decided improvement in the demand for slack in the bituminous market, though the local trade is not offering it at a very uniform price. There is a certain lack of confidence in this trade, as a result of a long period of control by the consumer, that keeps most dealers from making a steady price and sticking to it.

The late holiday season was not over before there came on a week or more of severe weather, so that the output of all mines tributary to this market has been unusually light. In fact, the entire January output will be much smaller than anyone would have estimated, but the trade is not able to obtain any advance in prices. The expected stocking up against a possible strike does not materialize, which is a great disappointment also. In fact, the dealers as well as consumers are about agreed that the prospect of an April strike is small.

As a rule the orders on contract are more liberal than they were. The cold weather would alone insure an increase, and business is at least as good as it was last year. Quotations are therefore a little more confident at $2.50 for Pittsburg three-quarter, $2.40 for mine-run and $2 for slack. Coke is stronger at $4.25 for best Connellsville foundry and $3.50 for stock coke.

Cleveland, Ohio

Conditions in this market the past week have been rather serious on account of coal not being brought in by the railroads. Prices on all grades have increased in consequence, more especially in slack coal.

A number of mines in the Ohio district have not worked on account of the severe weather, which disabled their equipment, and the coal in transit has been delayed on account of snow blockades. In the past few days, however, the railroads have brought in considerable coal, which was quickly delivered to the customers, and now little is remaining on track and the prospects do not look bright for any large quantity coming in the next week.

Conditions, however, up to the present have not developed any serious shortage, but should the weather continue severe, there certainly will be a shortage in the next 10 days. Coal has been in transit from mines in West Virginia to this market for some 13 to 14 days, which should arrive here, when conditions are normal, in about four days. The same thing exists in the Ohio and Pennsylvania districts.

Columbus, Ohio

While the weather during the early part of the year was favorable for a good demand, it also interfered with mining and transportation, and now coal men are clamoring for higher temperatures. The change in the thermometer came toward the middle of last week and as a result conditions have improved.

The demand for domestic grades is still good and prices are ruling firm in every particular. There is also a good demand for the steam grades and as has been the case for some time prices for the small sizes are up. The fine-coal trade has been the feature of the market since the close of Lake navigation, and prices have steadily risen from 35 and 40c. until they are now 75 and 80c. Even at these prices fine coal is difficult to secure and many manufacturers are using mine-run instead. Retailers have been having a harvest, with prices strong and up to the usual winter level in many cases. There is also quite an appreciable increase in the requisitions of manufacturing establishments for steam tonnage.

Prices which prevail in Ohio fields are:

Domestic lump in Pomeroy Bend district	$1.65@1.75
Domestic lump in the Hocking Valley	$1.50
Three-quarter inch	1.35
Nut	1.15
Mine-run in eastern Ohio	1.00@1.05
Mine-run in the Hocking Valley	1.05@1.15
Nut, pea and slack	0.70@0.80
Coarse slack	0.60@0.70

Cincinnati, Ohio

The last week has been a strenuous one for the coal men in this market. To add to the ordinary troubles, such as tie-ups on the railroads, there has been a serious river situation which at this time threatens to parallel the excitement of several years ago when thousands of tons of coal were lost in the Ohio River by reason of ice gorges and later high water.

The extreme weather undoubtedly cleaned out any free coal that was on the market, but it is predicted that with the easier movement of coal resulting from the warm weather there will be another large amount of fuel ready for delivery and concerns which have been ordering more freely than they could store, in the hope that someone would be able to ship, will find themselves overstocked unless another cold snap should again relieve the situation. Such another extended cold spell would indeed put a keen edge on the market. The retail price of domestic fuel was advanced 25 to 50c. a ton, but this was due to the increased cost of delivery on account of the ice and snow. It was stated by dealers that even this did not nearly cover the added expense.

Charleston, W. Va.

Conditions have undergone no material change. The cold weather has continued to affect mining and shipping but prices for domestic are as good if not a little better than reported last week. With the breaking of the weather, however, production will increase and the output for the month will, in all probability, show a considerable increase over the same month last year, which was below the average.

A shortage of cars on the Kanawha & Michigan caused a shut down at nearly all the mines the latter part of last week and the early part of the present one. The shortage is reported to be due to a block on the lines in the Middle Western states, causing a slow return of the cars. The Kanawha & Michigan was the only line in West Virginia that during the past year caused any serious delays at the mines through car shortage. All the coal over this line, however, goes West and North—the lake points and Western markets.

Louisville, Ky.

The local coal situation remains practically unchanged. The flurry resulting from the record breaking cold spell, when dealers in both domestic and steam coals were pushed to the limit to supply the demands, passed away without any serious trouble. Prices are remaining unchanged and it seems now as if there will be little change before the drop which always accompanies the coming of spring. One thing seems certain and that is if the Louisville dealers can handle a situation such as that early in January, they will be able to meet most any condition which may develop this winter.

Nashville, Tenn.

One cold spell of weather continues to follow the other, and the conditions in the cities and towns in this district are critical. They are all practically out

of coal; there is no regular price and nearly anything is offered for spot shipments.

A bad shortage of cars was in evidence during this week on the L. & N., and this, together with freezing temperatures in the mining fields, was the cause of the entire district not being able to produce over 40 to 50% of its usual tonnage. The way it looks at the present time is that the only thing which can save the situation is at least one week of unusually mild weather accompanied by a good supply of empty cars for loading.

Screenings are still in big demand. This is the time of the year that many of the large users of screenings attempt to accumulate storage piles for the spring months when the mining of lump coal ceases. But it has been all that they could do to get enough to run from week to week; consequently they have accumulated nothing and will very likely find themselves in a bad fix this coming spring.

Indianapolis

The situation here has well nigh cleared up toward the close of the week. Of course, there is a stack of orders from the Northwest, to be filled as soon as possible. The commission found that the 16-hour law greatly hindered the railroad companies from rushing shipments. Under this law the crew may not work over sixteen consecutive hours.

Coal prices here and elsewhere in the state have been increased on an average of 25c. a ton. Local dealers say that the stock of coal is low, but they do not anticipate a famine.

Chicago

Milder weather has resulted in a softening of the market and a decline in the unusual prices that prevailed during the recent cold snap.

The full effect of the change is not yet apparent, but there are enough indications to demonstrate that a downward movement is well under way. Coal dealers do not expect a remarkable drop, but the decline, they say, will be of a substantial character.

A scarcity of coal has been one of the chief features in the recent market excitement. Service on the Chicago & Eastern Illinois has been crippled, and the Illinois Central has had thousands of cars of coal which it was unable to handle. Almost every effort to move smokeless coal in this market has been blocked at some junction point. Freight-traffic managers of Western roads say that with a rising temperature a heavy influx of coal in the Chicago market may be expected, and marked alterations in price schedules now in effect are sure to follow.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.62@2.87
Steam lump	2.37@2.87
Screenings	2.37@2.87
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.32@2.82
Mine-run	2.32@2.82
Screenings	2.32@2.82
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.27@2.77
Mine-run	2.27@2.77
Screenings	2.27@2.77
Pocahontas and New River:	
Mine-run	$3.15@3.30
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.50@4.65; byproduct, egg and stove, $4.85; byproduct, nut, $4.55@4.65; gas house, $4.85.

St. Louis, Mo.

Conditions this week are somewhat on the order of last week, with the exception that the market has broken considerably. It is impossible to give any scale in prices, for, while Carterville opened at $2 for lump and egg, there were times when it went down to $1.65, and the Carterville sizes of nut were much on the same order, going at $1.60 as an average. Carterville screenings opened at about $1.25, but broke during the middle of the week, although indications are that they may go higher the latter part of the week. This same thing applies to Franklin County when it comes into St. Louis, but the past week or two has seen little of this coal in this market.

There is no Saline County nor Springfield coal coming in, and Murphyboro Big Muddy is hard to get at any price. The Mount Olive coals started out at about $1.90 at the mines, but has weakened some, as the demand is not as great, and coal is now moving freer.

Minneapolis—St. Paul

Cold crisp weather has continued throughout the present week, but has not been so severe as during the first two weeks of the month. A few cars of coal have been received at the various yards and some record-breaking time has been made in cleaning them up. Railroads are confiscating considerable coal for their own use. Hard coal is scarce, especially stove and the smaller sizes. Nut coal has not been sold as readily as in former years. Last year the price of nut coal was raised 25c. and dealers claim it had a tendency to stimulate the demand for other sizes.

Retail prices have not advanced any, with the exception of Pocahontas lump and egg, which advanced 25c. per ton, when the price at the docks was raised 50c. Wholesale prices at the docks are reported to be at circular. Illinois mines have all withdrawn price lists, and a number have no coal for sale at all.

Circular prices in the Twin Cities are as follows:

Anthracite	F.o.b. Dock	Minn.-St. Paul	Retail Delivered
Egg and stove	$6.50	$7.75	$9.00
Nut	6.75	8.00	9.25
Pea	5.25	6.50	7.75
Buckwheat	3.75	5.00	6.25
Pocahontas			
Lump and egg	5.00	5.90	7.50
Mine-run	3.25	4.15	5.50
Screenings	2.75	3.65	5.00
Sunday Creek Hocking			
Lump	3.50	4.40	5.75
Stove	3.50	4.40	5.75
Dock-run	3.10	4.00	5.35
Screenings	2.25	3.15	4.50
Youghiogheny			
Lump	3.50	4.40	5.75
Dock-run	3.20	4.10	5.45
Screenings	2.50	3.40	4.75
Smithing	4.25	5.15	6.50
Cannel (all rail)			8.00

Portland, Ore.

The cold spell that swept over this territory did not last long and as soon as it was over, the rush for fuel ceased with the melting of the snow and ice. So abrupt was the check on the business that dealers have seen fit to reduce coal values 50c. per ton, bringing the price on Australian and Rock Spring coals down to an even $10 per ton, including cost of delivery within the city. Bunker coal is quoted at 50c. less per ton, but there has been no demand for such coal here for some time. The coasting steamers are burning oil and the foreign steam craft that come here are either fully supplied or coal at British Columbia. Vessels in the oriental trade usually carry coal from the other side.

Production and Transportation Statistics

Chesapeake & Ohio Ry. Co.

The following is a statement of the coal and coke traffic over the lines of the Chesapeake & Ohio Ry. for November, and five months ending November, 1911, in short tons:

Destination	November	5 Months
Tidewater	284,872	1,603,154
East	200,002	869,036
West	825,597	4,798,682
Total	1,310,471	7,270,872
Coke	18,605	93,040
From Connections		
Bituminous	18,464	94,122
Anthracite	2,273	15,411
Grand total	1,349,813	7,473,445

Norfolk & Western Ry.

Statement of total coal and coke shipments over the N. & W. Ry. for December and the year 1911, in short tons:

Destination	December	Year 1911
Tidewater foreign coal	101,118	995,400
Tidewater foreign coke	5,713	75,867
Tidewater coastwise coal	293,850	3,084,674
Other domestic coal	1,413,644	15,363,913
Other domestic coke	116,988	1,434,985
	1,931,313	20,954,839

Ohio Coal Traffic Statement

Statement of bituminous coal mined in Ohio and shipped over railroads specified, November and first 11 months of 1910 and 1911, in short tons:

OHIO COAL TRAFFIC STATEMENT

Railroads	November 1910	November 1911	Eleven Months 1910	Eleven Months 1911
Hocking Valley	465,215	444,543	4,301,978	3,306,526
Toledo & Ohio Central	218,601	204,767	2,007,069	1,743,903
Baltimore & Ohio	199,434	199,388	2,237,989	1,647,304
Wheeling & Lake Erie	356,010	392,082	3,459,033	3,353,577
Cleveland, Lorain & Wheeling	249,685	298,420	2,813,142	2,795,274
Zanesville & Western	109,976	124,261	1,088,447	1,048,866
Toledo Division, Pennsylvania Co.	209,006	196,708	2,069,139	1,743,890
Lake Erie, Alliance & Wheeling	142,448	122,326	1,166,382	1,142,741
Marietta, Columbus & Cleveland Ry	7,098	2,248	90,042	24,541
Wabash, Pittsburg Terminal Ry	7,155	1,072	62,071	53,097
Kanawha & Michigan Ry	....	19,103	....	104,747
Total	1,964,628	2,004,918	19,295,292	16,964,466

Imports

The total fuel imports for November, 1911, were 102,475 tons, valued at $299,-443, and for the first 11 months were 1,101,228 tons, valued at $3,241,478.

Coastwise Movement

Statement of domestic coal shipments by water from five principal Atlantic ports for November and first 11 months, 1910 and 1911, in long tons:

Ports	November	11 Months
New York	2,344,362	22,907,744
Philadelphia	617,832	6,444,082
Baltimore	246,186	3,904,028
Newport News	228,382	2,440,418
Norfolk (1)	423,040	4,214,834
Total, five ports	3,859,802	39,911,106

(1) Includes amount shipped by the Virginian Railway at Sewells Point, Va.

Exports

The total exports for November, 1911, were 2,122,753 tons, valued at $6,621,-927, and for the first 11 months of the year 23,139,169 tons, valued at $71,377,-595. These figures include bunker fuel laden on vessels in foreign trade.

Various Railroads, Rivers and Canals

Statement of coal and coke movement over different railroads, rivers and canals for November and first 11 months, for the years 1910 and 1911 was as follows, in short tons:

COAL AND COKE MOVEMENT OVER VARIOUS RAILROADS, RIVERS AND CANALS

Railroads	Month of November 1910	Month of November 1911	Eleven Months 1910	Eleven Months 1911
Baltimore & Ohio[1]	3,159,141	3,403,842	33,712,324	32,208,476
Buffalo, Rochester & Pittsburg[3]	746,010	750,748	7,438,306	7,497,928
Buffalo & Susquehanna[3]	170,115	178,649	1,580,855	1,768,109
Chesapeake & Ohio[1 2]	1,125,020	1,588,262	13,659,569	13,589,330
Erie[3]	581,166	667,786	5,805,619	6,678,894
Huntingdon & Broadtop Mountain[1 3]	100,478	101,593	1,150,281	1,012,111
New York Central & Hudson River[3]	703,777	723,061	7,194,792	7,351,102
Norfolk & Western[1 3]	1,698,876	1,962,155	18,427,493	19,023,526
Pennsylvania (east of Pittsburg and Erie)[1 4]	5,747,408	5,961,138	60,047,801	58,908,439
Pittsburg & Lake Erie[1 4]	1,472,209	1,440,529	16,483,283	14,846,979
Pittsburg, Shawmut & Northern[3]	127,956	139,538	1,146,812	1,323,189
Southern Railway[2]	378,886	350,290	3,564,793	3,156,688
Virginian Railway[1 3]	222,297	288,621	1,492,386	2,558,332
Western Maryland Railway	250,501	227,058	2,979,255	2,412,906
Rivers and Canals				
Chesapeake & Ohio Canal	22,112	22,568	184,882	186,440
Davis Island Dam	80,200	166,870	1,660,495	2,554,140
Monongahela River	683,247	810,348	8,703,580	8,296,493

[1] Includes coal received from connecting lines. [2] October and ten months' figures. [3] Includes company's coal. [4] Does not include company coal hauled free.

Foreign Markets

Germany

The production, imports and exports of fuel in the German Empire for the first 11 months of 1911 was as follows, in metric tons:

	Production	Imports	Exports
Coal	147,309,185	9,958,356	24,806,125
Lignite	67,081,079	6,463,976	52,582
Briquettes	*20,029,757	195,984	2,236,907
Coke	23,025,879	549,013	4,079,834

*Including subsequently reported quantities.

Great Britain

The following is a comparative statement of the British exports for the years 1910 and 1911, in long tons:

	1910	1911
Anthracite	2,445,932	2,454,523
Steam	45,190,390	47,119,017
Gas	10,142,708	10,504,172
Household	1,549,735	1,540,710
Other sorts	2,776,711	2,980,844
Coke	964,053	1,064,839
Briquettes	1,470,791	1,612,741
Totals	64,520,320	67,276,846

The outlook in regard to the labor situation is serious, and strong conditions are in evidence in nearly all departments for early deliveries. For backward loading most sellers are inclined to hold their coal in the meantime. Quotations are approximately as follows:

Best Welsh steam coal	$4.32@4.44
Seconds	4.20@4.32
Thirds	3.84@3.96
Best dry coals	4.14@4.20
Best Monmouthshire	3.90@3.96
Seconds	3.66@3.72
Best Cardiff small coals	2.34@2.40
Seconds	2.16@2.22

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½% discount.

Spain

Imports of coal into Spain for the first 11 months of 1911 were 1,864,315 tons as compared with 1,828,108 tons for the same period in 1910. Coke imports for this period in 1911 were 293,841 tons as compared with 268,690 tons in 1910. Practically all imports are from Great Britain.

Financial Notes

Lehigh Coal & Navigation Co. has declared the regular quarterly 2% dividend, payable Feb. 29, to stock of record Jan. 31.

Jefferson & Clearfield Coal & Iron Co. has declared the usual semi-annual dividend of 2½% on preferred, payable Feb. 15 to stock of record Feb. 6.

The Dominion Coal Co. has declared the regular semi-annual dividend of 3½% on its preferred stock, payable Feb. 1 to holders of record Jan. 18.

The Colorado Fuel & Iron Co.'s charter expires on Oct. 21, 1912. Under the Colorado laws the company may apply for a 20-year extension on a vote of two-thirds of the stock outstanding.

The Pittsburgh Coal Co., contrary to expectations, earned the 5% dividend on the preferred stock in the fiscal year ended Dec. 31, 1911, according to officers of the company. Payment on the preferred dividend takes $1,353,590. In 1910 the earnings applicable to the preferred dividend amounted to $1,965,450.

The Reading Coal & Iron Co. has done an annual business of $35,000,000 without paying dividends. To a speculator this fact at once suggests large buried equities, since it is not conceivable that the coal company has been doing business without earning the same handsome margin of profit that other hard-coal concerns have made.

Joseph H. Hoadley, who is absolutely in control of the Alabama Consolidated Coal & Iron Co. as yet, is endeavoring to have $490,000 first consolidated gold 5s underwritten for the purpose of taking up and retiring the $426,000 first extension and improvement sinking fund gold 6s, which are held by the St. Louis Union Trust Co. as security for borrowed money. As the first-named bonds will probably not yield to the company more than 80, and the bonds which it is intended to retire with the proceeds of the sale are worth par, there will be a difference of $29,000 yet to be paid, which will be included in the general financing of the merged company, so it is said.

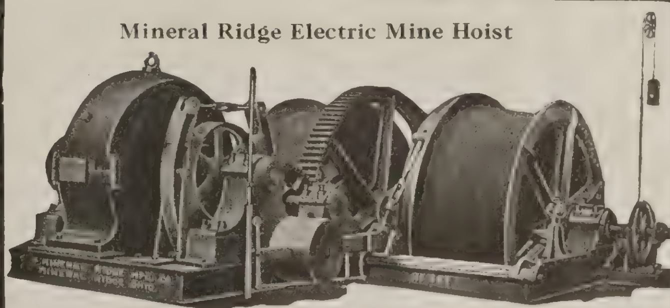
Mineral Ridge Electric Mine Hoist



Efficient And Reliable Under Any Conditions

Mineral Ridge Mine Hoist

Because of their *reliable* efficiency and their lasting efficiency, Mineral Ridge Hoists are suited to give most satisfactory service under any mine conditions.

They are so arranged that they can be operated from a distance, or can be made entirely automatic in action. Easily controlled, have a very low operating cost, and are perfectly safe at all times.

You will find that Mineral Ridge Hoists, either steam or electric, will answer your hoisting requirements in the most satisfactory manner.

THE MINERAL RIDGE MFG. COMPANY

MINERAL RIDGE, OHIO

Positions Vacant

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—An experienced mine electrician who can wind armatures and keep in thorough repair, a half dozen direct current generators, a dozen locomotives, and several motors located at different mines; location a plain mining camp, on short branch in central West Virginia. Wanted, by same company, a superintendent-foreman for small mine having an output of 400 tons per day, man who can survey preferred; state age, experience fully, where obtained, in what positions, education and where obtained, married or single, teetotaler or otherwise, and salary expected. Address Box 7, Coal Age. Feb. 3.

Wanted—Coal miner, to run undercutting machine or act as shift boss on American-owned mine in Arctic region; salary $125 per month and expenses, beginning May 1; two-year contract. Full particulars to "Arctic," 1004 Oliver Building, Boston.

Situations Wanted

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—Contract work (mine, mill, etc.), or assistant, by married physician; one year hospital experience; also private practice in Pennsylvania. Address Box 5, care Coal Age. Jan. 27.

Position wanted as manager or general superintendent; twenty-eight years' experience in mining, and have filled positions from door boy to general superintendent; I am a graduate mining engineer, familiar with every detail in producing, washing and coking coal, including costs and accounts; married and temperate in habits; references furnished. Address Box 6, care Coal Age.

Position as assistant superintendent or superintendent is desired by a man of ability and push, having two first mine foreman certificates, gaseous mines or otherwise, expert on ventilation, opening new mines and reopening old mines, by salary or contract; best of references furnished on request. Address Box 9, care Coal Age. Feb. 10.

Wanted—To get into communication with bituminous coal mining company which is in need of a high class mining engineer or superintendent; am thoroughly conversant with all modern and uptodate methods of mining, mine development, haulage, power, coal cutting and coal handling machinery; am well up on the question of costs and with my experience and knowledge of mining am able to take the kinks out of an expensive operation and reduce the cost; only a strictly first class proposition will be considered; can furnish highest references. Address Box 8, care Coal Age.

C A

COAL AGE

Vol. 1 NEW YORK, FEBRUARY 3, 1912 No. 17

THE bitter fight of the socialist element of the United Mine Workers, to have the Indianapolis convention indorse *government ownership of industries*, and declare for *political as well as industrial union*, compels attention of thoughtful men to the recent amazing spread of socialistic sentiment.

No intelligent person any longer believes that the industrial world will go back to an unorganized individualistic production and distribution of wealth. In fact, the most radical utterances, or what is termed "advance thought," concerning the regulation of big business, have emanated lately from our famed captains of industry; men who were expected to champion individualism in its highest degree.

A glance at the record of events leading up to the advent of the present social and industrial situation shows there is little occasion for surprise. With an insistence no less certain than the laws of gravity, social evolution has pursued its steadfast way. The advance has been of necessity born, and arguments as well as pleas have failed to retard its progress.

A couple of centuries ago, the lighting of streets in towns was a matter of individual enterprise; every householder was supposed to have a lantern before his door. The system failed through the selfish neglect of the individual and it was necessary to create laws compelling the display of a street light at each house. Soon it became apparent that the lighting of the streets was for the common good, and therefore was a communal function; immediately the householder was relieved of individual duty, and who of us would care to return to the early practice?

In like manner, every house once had its own well. But it was perceived that water was a common necessity, and the community undertook to furnish the supply. Lately, many people want to know, "why the supplying of water and light is any more a communal function than the supplying of artificial heat or the provision of transportation in our streets"? Probably in the future, as in the past, the science of one age will be the common sense of the next.

The cry has always been raised, "Don't deprive the world of the incentive that lies in individual effort." However, the early malcontents have been hushed, and we are today wrestling with the greater problem of how to democratize business. We have wallowed in the throes of excessive competition, the certain outgrowth of which is excessive coalition. The proposed remedy for the latter may be one thing, or it may be another—whatever the cure, it has yet to be proved.

We of the coal industry have little to fear and perhaps much to gain from the application of newer theories and the more restricted regulation of our business. When Prussia wanted coal mines, she went into the market and bought enough stock to give her control. New Zealand followed the same plan and the fuel industry in both countries was helped rather than hurt by the move.

Without holding any brief for socialism, or entering into a discussion as to whether the principles of the creed can be safely applied, we are secure in saying that such outbursts as occurred at the miners' convention are prophetic, rather than ominous. Many coal men with much at stake now invite reasonable government regulation, and if the will of the people goes further and demands government ownership, there is no doubt but that Uncle Sam can buy one mine, or many—all are for sale; sentiment won't interfere.

The principal danger to society today is from the inability or refusal of many people to distinguish communism and nationalism from socialism. The motto of the latter is, "Every man according to his deeds"; that's not so bad. What we have to fear are the disciples of the other two forms of social faith; these men too often follow the red flag of industrial death and physical violence. Firedamp in the mine is no less deadly when called by a different name, and hydrogen sulphide is just as foul when corked in a bottle labeled "Attar of Roses" It's the man behind the mask we dislike most—the pirate who strives to loot under the guise of a patriotic support of a plausible principle.

The Lignite Fields of Colorado

By R. A. Pierce *

Description of a field that holds an important place in the commercial trade of Colorado. The coal is a high-grade lignite and the seams vary from 4 to 11 ft. in thickness. Machines are used, and, as a general rule, the mines are dry.

*Chief engineer, Northern Coal & Coke Co., Denver, Colo.

The lignite coal fields of Colorado lie in the northern part of the state and immediately east of the Rocky Mountains. The workable beds are irregular in outline and extent, and are mainly confined to Boulder County and the southern part of Weld County. Coal has been found as far north as Wyoming, but its quality is such that it has no commercial value. It has also been mined to the west of Denver near Golden, and to the east near Scranton, but was never extensively developed owing to the inferior quality.

The field is divided into five general districts. The Marshall district, the Erie district, the Louisville district, the Lafayette district and the Dacono district. Each district is named after the principal town in that section. The working seams are all geologically related to one another, but have become separated and distinct by faults or erosion.

Rex No. 1 Mine, Louisville, Colorado

Historical

Coal was first mined around Marshall in 1863 and it is one of the oldest, if not the oldest district in the state. In 1864, which is the earliest record obtainable, 500 tons was produced in this field, the product coming from the Marshall, Golden and Scranton mines.

Closely following the opening of the Marshall field, development of the mines around Erie was started. With the completion of the railroad, and the rapidly increasing demand for coal, the production of the Erie district for 1872 was 54,340 tons. The mining excitements and the rapid growth of Denver and adjoining mining towns, created a heavy demand and the mines were soon working to capacity. Together with the Marshall mines this district produced the main supply of coal until 1888.

Next of importance was the opening of the Simpson mine in Lafayette, and the reopening of the old property at Louisville known as the Welch mine. Other openings followed in rapid succession and today the bulk of coal produced comes from these two districts.

The Dacono district is the newest one in the field. In 1907 the first properties were opened and eight mines are at present producing, the largest of which is the Puritan.

Geology

The coal beds are entirely confined to the sandstone and shales that constitute the Lower Larimie formation of the Upper Cretaceous period. The general stratigraphic conditions remain practically the same from Denver to the north line of the state.

On the west, and along the foothills, the formation is considerably disturbed, the strata having been sharply upturned, which together with numerous faults and folds, has complicated mining operations. At Marshall we find the greatest displacement has taken place, the coal being broken and numerous croppings found. Two general faults originate to the south of town, and traverse the coal in a northeasterly direction. The main, or north fault has a general trend of N 40° E, but gradually swinging north, while the fault on the south runs in a more easterly direction. The area south of this latter fault has been but slightly disturbed and contains a large body of workable coal; little, however, has been removed from this side of the fault, the earlier workings being on the north.

From the foothills, the coal rapidly flattens out to the east, and is in a more nearly horizontal position, with a general dip to the south and east which follows closely the contour of the prairie.

The deposition of the coal is mostly in synclines, separated by folds which have become eroded and in many cases

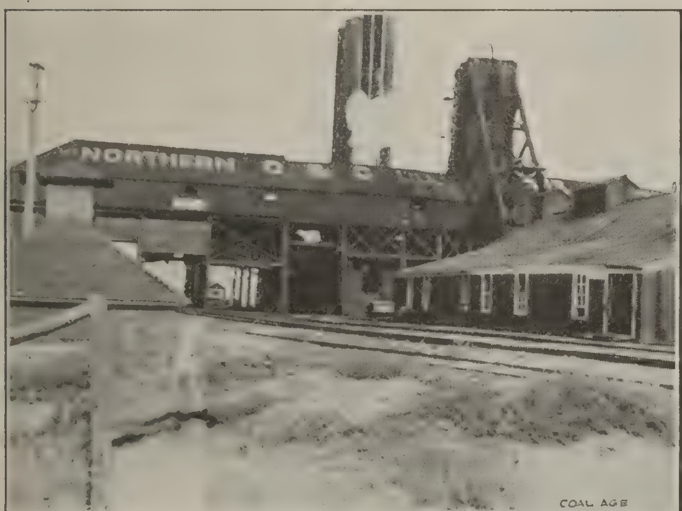
faulted. The axes of these synclines are northeast and southwest, and the basins have a varying width of from one to three miles. Local faults, of light throw, are encountered in mining, especially in the Louisville syncline.

The Coal

Most of the coal seams lie within 300 ft. of the surface and vary in size and number in the different districts. At Louisville, two seams about 60 ft. apart are worked, and the seams commonly mined vary in thickness from 4 to 11 ft. Coal under 4 ft. is considered unworkable under present conditions, but as the thicker coal is exhausted and the demand increases, 4 ft. and even 3 ft. will be worked at a profit.

Industrial Mine, Superior

Gorham Mine, Marshall



Views of Simpson Mine, at Lafayette, Colorado, Showing Tipple, Power Plant and Machine Shop

The general character of the coal throughout the district is the same, although that nearest the foothills is of a superior quality, due to regional metamorphism.

The coal represents the highest grade of black lignite, although according to the carbon-hydrogen ratio classification, it closely approaches the lower-grade bituminous. The physical properties are such as would indicate that it belongs to the lignite coals; namely, a lower specific gravity, burning with a clean flame, noncoking and slaking on exposure. This coal has been classified by the government as a sub-bituminous.

The following is a typical average analysis for coals in the different districts:

District	Carbon	Hydrogen	Nitrogen	Oxygen	Sulphur	Ash
Marshall	67.03	5.15	1.25	22.50	0.30	3.77
Erie	65.95	5.23	1.40	22.83	0.43	4.16
Louisville	66.03	5.00	1.28	23.08	0.43	4.18
Lafayette	65.10	5.13	1.25	21.58	0.29	6.65
Dacono	65.33	5.00	1.40	21.07	0.46	6.74

The coal shows an average calorific value of 11,200 B.t.u. in air-dried sample. The moisture is variable, being less in the western portion and increasing to the east. For producer-gas purposes, the tests made at St. Louis by the government, show satisfactory results, 1.71 lb. of dry coal giving one electrical horsepower as compared with 4.85 lb. under the steam boiler, showing a gain of 183 per cent. in efficiency.

Prospecting and Developing

The irregularity of the coal beds renders imperative the thorough prospecting of any tract before starting operations. The usual method of prospecting is with the churn drill, using pipe rods. Faults and splits in the coal can be determined easily and without great expense, owing to the light cover and the soft overlying strata. Satisfactory results have been obtained with the churn drill as shown by checking the actual measurements of the coal whenever exposed in the workings, with the records as shown by drilling.

The following table will show the relative cost per foot throughout the district. This includes all costs except casing:

Depth	Cost per ft.
0 to 400	$0.50
400 to 500	0.75
500 to 600	1.00
600 to 700	1.50
700 to 800	2.00

The size of the hole on starting is dependent on the depth it is expected to go.

The area worked by one shaft as a general rule is not great, and accounts for the large numbers of mines, short life and the less expensive equipment used. The new plants, which have been installed in the last few years, are more modern and uptodate, and more territory is acquired and systematically drilled and prospected. The shafts are placed near the center of the property, or if the measures have a definite pitch the shaft is sunk with reference to securing the proper ventilation and drainage of the mine. First-motion hoists, self-dumping cages and other improved labor-saving devices are also being used in the newer plants.

Methods of Development

The greater part of the coal is taken out through shafts which vary from 50 to 275 ft. in depth. These are usually three-compartment shafts, two for hoisting coal and the third for pipes, ventilation and manway. The cages are single deck and carry one car.

The room-and-pillar system is used generally through the field. The usual method of exploitation is to drive two parallel entries, with 50-ft. pillars, in opposite directions from the shaft; cross entries are then turned at intervals, depending on the length of the rooms, at 90 deg. to the main entry, 175 to 225 ft. being the average length of the rooms. These cross entries are carried to the boundary line, if the distance is not great, the rooms being worked as the entry advances and the room stumps and chain pillars removed on the retreat. When the territory to be developed is large, additional entries are driven parallel to the main entry, at intervals of about 700 ft., blocking the cross entries into panels.

Casino at Hecla Mine, Louisville

By maintaining one pair of cross entries as a main haulage road, the coal from all panels can be delivered to the shaft with a minimum amount of haulage. Rooms are driven on sights and about 36 ft. on centers, 20 ft. being the average room neck.

The roof is mostly shale and disintegrates readily on exposure to the air. Where the thickness of the coal will permit, roof coal is left to protect the entries. Timbering is required in all the rooms.

The methods of mining throughout the field are comparatively simple, and only slight changes in the different districts are necessary, due to the difference in the physical characteristics of the seams. The measures are approximately flat, and the minor faults are not troublesome. The water made is not excessive, except possibily in the Erie field, where constant pumping is necessary. Very little gas is encountered and no serious trouble has ever occurred from this source. Under these favorable conditions, mining with some definite plan of operation is easily accomplished, and such a plan is generally adhered to, especially by the large companies.

Mining

The method of mining the coal at the face is with an undercut of about 4 ft. by air machines, and in coal up to 8 ft. thick, three holes are placed across the face about midway of the vertical height. The center hole is inclined to open a cut, and the side holes are placed near the rib to break the coal. The usual charge is about 12 to 14 in. of FF black powder.

Hecla Mine, Louisville

The pillar work is mostly hand mining and is started at the top of the room and drawn back to the stump. This is carried back in blocks of half the pillar or the full width. In cases where the pillar has been made larger than the average, which is 16 to 20 ft., a skip is first taken along the side.

Where bone or slate is encountered in the coal, it is removed in the mine, and in narrow work loaded into pit cars. These are taken to the surface and dumped. The miner is paid so much per inch-yard for removing slate or bone from the coal. In narrow work, where it is loaded into cars, 25 to 35c. per car extra is paid for loading, the price depending in the size of the car.

Wage Scale

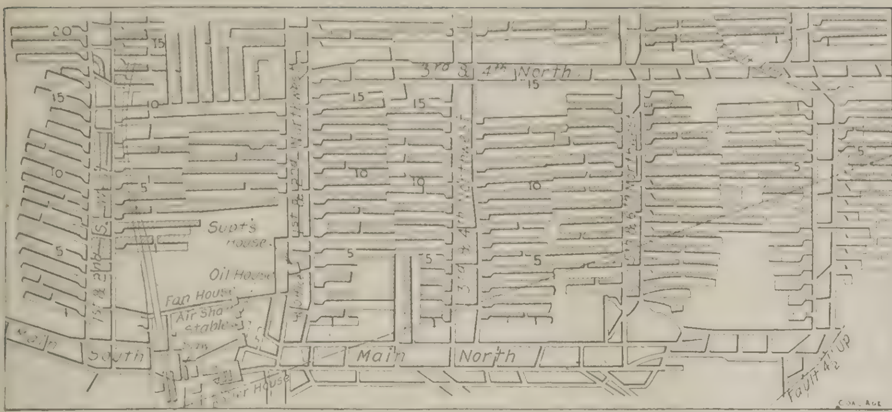
The price paid for loading coal after machines is from 34½c. to 43½c., depending on the height of coal and the district. Pick work runs from 47c. to 68⅔c., depending on the height of coal and the district. Narrow work is paid for by the yard, ranging from $1.20 per yard to $2.25, depending on whether hand or machine mining.

The total number of men employed in and about the mines will average 1750 for 1908-9-10. Coal is hoisted for eight hours during the day, the shift commencing at 7.30 a.m. and working until 4 p.m., one-half hour being taken at noon.

The coal is put on the market in three sizes, run-of-mine, lump and slack. The lump is made by passing over a 2½-in. shaking screen and the slack is the coal passing through a 2½-in. screen. The average proportion of lump and slack coal is 60 per cent. lump, 40 per cent. slack.

Surface Equipment

The mine cars are dumped over home dumps in most cases, the car crossing over the tipple scales before passing into the dump. Two dumps are provided, one



Map of Lehigh Mine, Illustrating Typical Method of Working

for each compartment, in mines where the empty cars cannot be run around the shaft and caged, as the loaded car is removed. Crossover dumps are used on tipples having room enough to operate. As most of the mines are operated from both sides of the shaft the bottom is provided with switches and sidings permitting the coal to be caged from both sides.

An effort is made to keep the coal as clean as possible by removing the bone and slate before coming to the surface. The lump coal is loaded into box-cars to protect it from the weather, while the slack and mine-run are loaded in open cars. All precautions are taken to make the coal as merchantable as possible. Box-car loaders are used to load the lump coal.

The companies have built at each camp, accommodations for all their men, and can operate their mines independent of the towns which are situated in the districts. This policy was adopted after the labor trouble in April, 1910. Prior to this, most of the men lived in the town nearest to the mine in which they worked.

The camps have their own water system, the water being supplied from holes drilled to the artesian flow which is about 800 ft. deep. Streets have been laid out, and electric street and house lights are used in most of the camps.

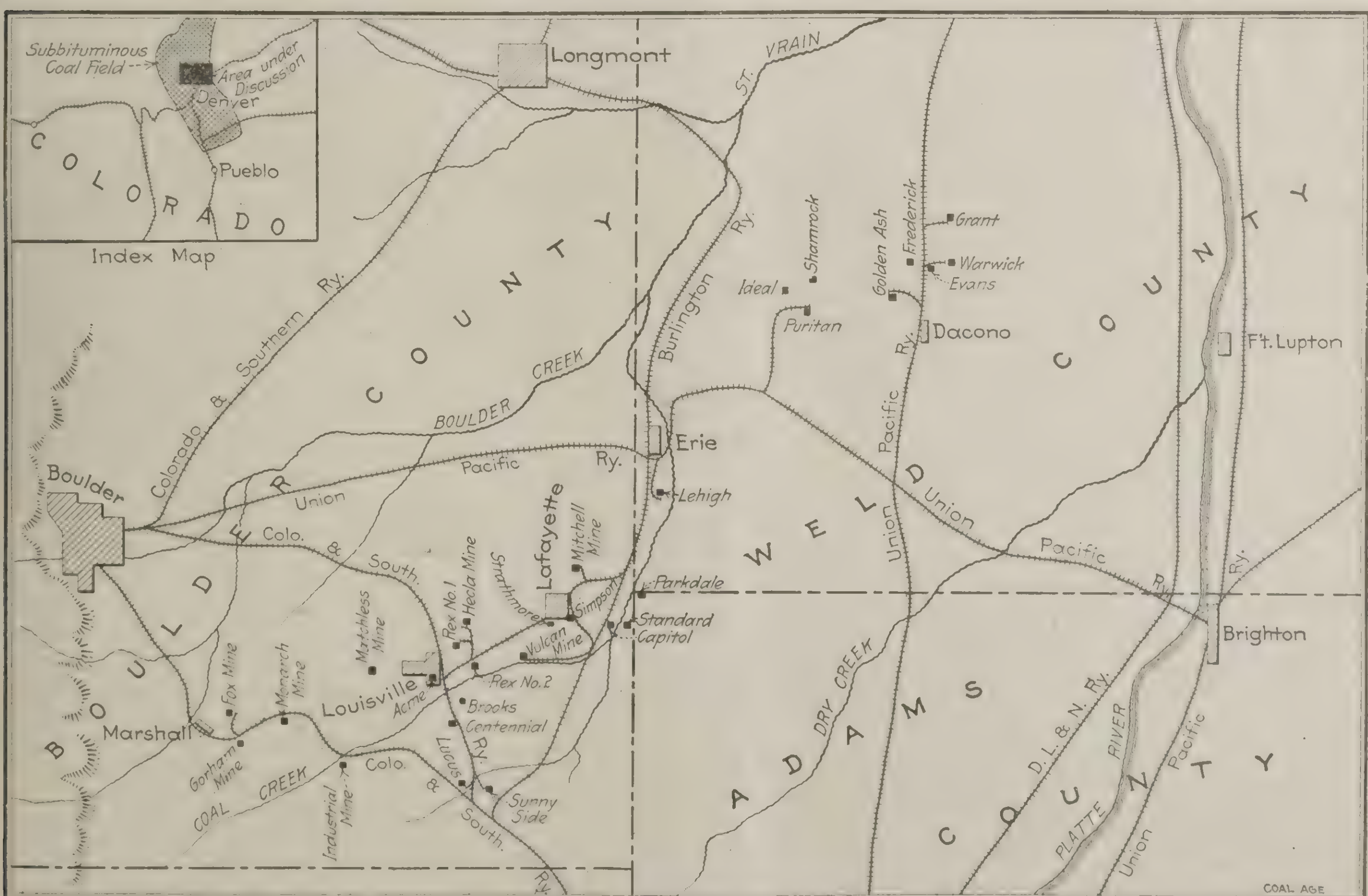
The houses are mostly of the four-room variety. A few five-room houses were built, but are not in demand by the ordinary coal miners. Large boarding houses have been built for the single men, the largest of which will accommodate 75 persons. Wash houses containing hot and cold water, cement floors and 74 lockers are placed in each camp.

We have built at our main camps, club houses for the amusement of the men and play grounds for the children. The play grounds are equipped with swings, turning poles, slides, etc. The casinos are equipped with pool and billiard tables, card rooms, reading room, store where soft drinks, tobacco and supplies are sold. The camps are all in charge of one person who is responsible for the sanitary condition and the order kept.

Summary.

The mine-run and slack coals are used for steam purposes, while the lump supplies the domestic trade in Denver and towns in the northern and eastern part of the state. During the winter months some coal is shipped into Kansas and Nebraska.

During the year of 1910 there were 33 mines in operation representing 21 separate corporations or individual operators. The largest of these companies is the Northern Coal & Coke Co., operating 10 mines. The National Fuel Com-



Portion of the Northern Colorado Lignite Field, Showing Railroad Connections

pany operates 4 mines and the balance are independent operators. The Northern Coal & Coke Co. produced for the year 491,770 tons and the National Fuel Co. 245,277 tons.

In the following table will be found the amount of coal mined in Boulder and Weld Counties for the last 11 years compared with the total production of coal in the State:

COAL OUTPUT OF COLORADO

Year	Total Production of State	Boulder & Weld Counties
1900	5,495,734	719,748
1901	6,210,405	559,131
1902	7,522,923	871,699
1903	7,775,302	918,807
1904	6,776,551	858,921
1905	8,989,631	978,443
1906	10,308,421	149,824
1907	10,965,640	1,602,946
1908	9,773,007	1,494,277
1909	10,772,490	1,665,068
1910	12,104,887	1,091,755

The decrease in 1910 was due to a strike being called in April, lasting throughout the year; although no settlement has been made up to the present time, the mines are all in good condition and ready to work full capacity during the winter months. There is some evidence that a strike may occur in southern Colorado; in this event, the lignite mines would be taxed to capacity.

European Wash House Practice

The question of the health of the miner is receiving especial attention in this country at the present time. In view of the important nature of the problems it will be useful to make a brief examination of the present methods of equipment adopted in this and other countries, particularly in such districts as the Belgian, where such provisions appear to be very fully adopted. On the Continent there is little difficulty in inducing the workers to take advantage of the facilities provided, and there appears to be a strong objection on the part of the men to appearing in the streets in a dirty condition. Of the tctai number of Belgian collieries, 45 are known to be provided with sanitary installations.

The Dolcoath Mine

The following particulars as to what has been done in the provision of baths at the Dolcoath tin mine in Cornwall are of interest. They were supplied to H. M. Chief Inspector of Mines, R. A. S. Redmayne, by R. Arthur Thomas, general manager of the mine.

The lavatory is contained within a brick building, 38 by 28 ft. (see Fig. 1). The sides of the room are occupied by 36 enamelled wash basins countersunk into a slate bench. These basins are provided with hot and cold water, and the waste therefrom is conveyed by a pipe into a half-round enamelled earthenware gutter. Ten bath-rooms, each 7 ft. 6 in. by 5 ft. 6 in., occupy the central portion of the building.

This structure is in the form of sectional partitions, each containing a bath. The gradient of the cement floor towards the enamelled earthenware gutter enables all the waste and overflow from the baths and wash basins to be conveyed away from the building.

The following details refer to the plan Fig. 1: *A*, wash basins, white enamelled 12 in. diameter, countersunk into slate bench *B*, and fitted with a pipe conveying waste into the enamelled earthenware gutter *D*. The baths *F* are enamelled inside and on the roll, and are complete with hot and cold globe cocks, plug, and pipe conveying waste into the gutter *D*.

This is the second of a series of articles on wash house construction. European practice (especially the Belgian) is further advanced than the American. This article is the most comprehensive yet published on the subject.

Note—Abstract of paper appearing in the Iron and Coal Trade Review (London), Nov. 24 and Dec. 5, 1911.

Each man before entering the bath usually has a preliminary wash of the hands and face in the basins provided, and the actual time occupied in the bathroom is from 8 to 10 minutes. On an average the men have a bath once a week, but may do so daily if desired. They do not contribute towards the cost of the upkeep or the interest on the capital expended. The "dry" and baths are under the sole control of the management.

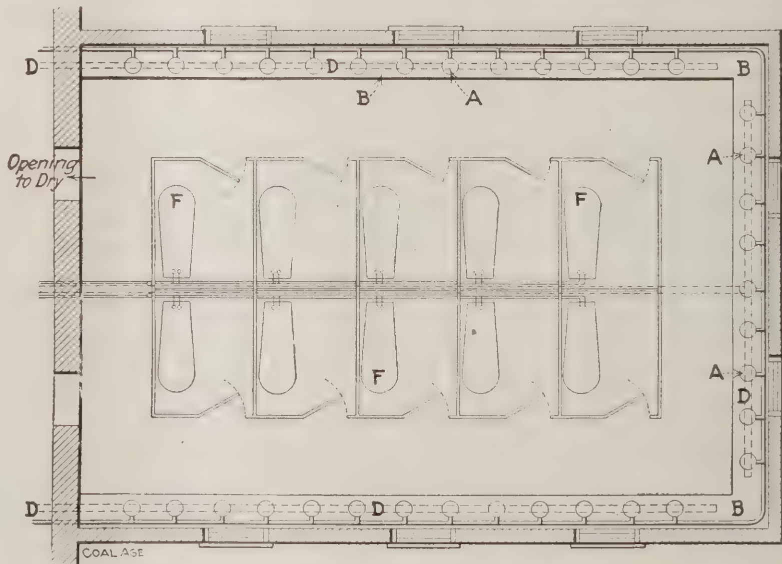


Fig. 1. Plan of Baths at the Dolcoath Mine

The Wharncliffe Silkstone Colliery

A beginning in the provision of miners' baths and changing accommodation was made some time ago at the Wharncliffe Silkstone Colliery, but is only for a small percentage (about 3 per cent.) of the 1825 persons employed. The following particulars have been kindly given by G. Blake Walker:

There are eight shower baths and six slipper baths, 48 lockers for clothes and an attendant's room, the initial cost being about $2400. The cost of upkeep (attendance, heating, lighting and depreciation) is $7.20 per week. The men using the baths each contribute 48c. per quarter and provide their own soap and towels. The baths are used with fair regularity by 48 men, but there is no demand for extension. A man can usually wash and change in 15 minutes; some do so in 10 minutes.

Monceau-Fountaine Collieries

The management of the Société Anonyme des Charbonnages de Monceau-Fontaine, which within recent years has equipped its pits at Pieton, Goutroux and Marchiennes with dressing-rooms and douche baths, has recently installed a fine equipment at its No. 8 pit at Forchies.

The central area is flanked on three sides with annexes. The central building is the dressing-room of the workmen. In the annexes are the entrance hall, the lamp-room, the miners' baths, the engineers' bathing-room, the space reserved

to the overseers, the women's dressing-room and baths, the clothes-room, and the room for the payment of wages.

The entrance hall gives access to the dressing-room and baths for the men and boys and to several accessory rooms, as will be noted in the plan, Fig. 2. It is for the use of the engineers, miners, etc., and is closed at the ends by swinging doors. It is capable of being warmed. The workmen's dressing-room is 130 ft. long, by 40 ft. broad, by 24 ft. high.

The Miners' Bath

Eight hundred men engaged at this pit daily use this room for changing clothes. Each man has his own clothes-hanger entirely to himself. The system of retaining the clothes consists of suspending them in the upper part of the dressing-room. Thus while the man is in the pit, or having left work has gone home, the warmed air constantly renewed by the ventilating appliances in the room traverses the damp or soiled clothing and dries and purifies them.

The suspension of the clothing is obtained by means of a small galvanized iron chain passing over two small pulleys fixed to a grille formed of sectional steel held by the roof trusses. When suspended, each set of clothes hangs clear of those of the other workmen. Each hoist is provided with a lock and key, the latter being kept in the possession of the user, so that theft is impossible. The only other interference with the free space of the dressing-room are the benches, of which there are eight.

Lamp Room and Engineers' Baths

Separate from the dressing-room there are two groups of miners' baths, comprising 120 cabins or compartments. Each cabin has two compartments. The first, closed in front by a sliding curtain, is used for dressing and undressing. The second, behind the first, has an overhead spray. All the cabins are finished in enamelled brick with rounded corners. They are reinforced with iron stays in the interior of the walls. The average time taken by a workman in the bath itself is about five minutes, and about nine gallons of water are used per bath.

TABLE 1. DETAILS CONCERNING EQUIPMENT OF EUROPEAN WASH HOUSES

Name of Colliery	Number of Shower Paths for Miners	Initial cost of installation	Maintenance cost per month, heating, lighting and attendance	Number of men employed	Number and percentage of men using the baths	Cost per bath, including soap, brushes and salaries of attendants	Number of clothes hoists

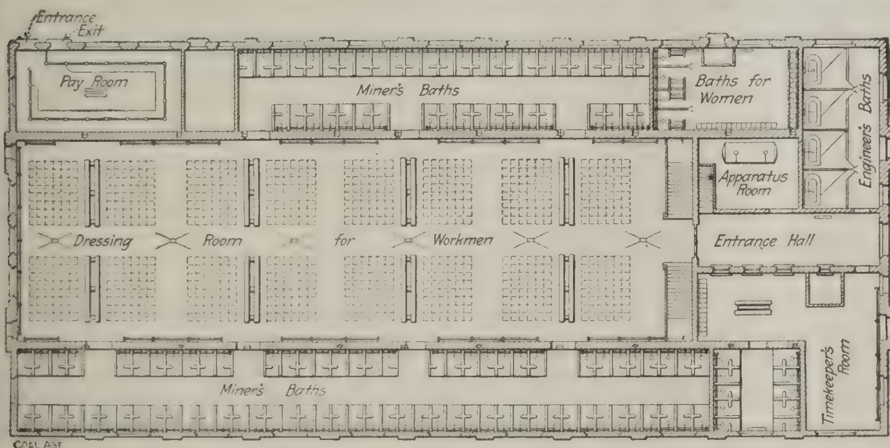

Fig. 2. Miner's Baths at the Monceau-Fontaine Colliery

The engineers' bath-rooms consist of four cabins of enamelled brick, 10x10 ft. and 6 ft. 6 in. high. A somewhat similar arrangement is installed at the St Charles pit of the Charbonnage Poirier. The engineers have at their disposal a bath of enamelled iron, fed by a bronze tap, which gives hot or cold water as required. A douche is also provided, and included in the equipment of the bath-room are a clothes chest, a chair, etc.

The Overseers' Bath

In the overseers' quarters, which include a dressing-room and bathing accommodation, is a clothes drier of iron with a double face suitably heated, and 20 clothes receptacles. The overseers have ten brick compartments in the bathing-room similar to those provided for the miners.

The water for the baths is mixed with steam in two mixers of boiling and cold water, thermometers indicating the boiler water temperature and that of the water going to the baths; the temperature is variable according to the different hours at which the supply is used. At night, both arc and incandescent electric lamps are used in order to provide efficient illumination in all parts of the building.

Twenty ventilation shafts placed in the walls of the central building and surmounted by cowls insure efficient ventilation, while ventilation of the dressing-rooms and lamp-room is also well looked after. Efficient means for the disposal of the waste water are also provided, and the whole equipment provides a notable example of modern hygienic principles applied in a most practical form to the purposes of a mine.

Belgian Practice

The accompanying table is submitted by R. A. S. Redmayne, giving particulars of thirteen installations in respect to cost of erection and maintenance of baths, and the number of persons using the same. The provision of douche baths was not obligatory before July 5, 1911.

By this law they have to be established and maintained at all new collieries, but the workmen are not obliged to use them.

In regard to the above it may be noted that at the St. Nicholas and Bonne Fortune pits there are six shower baths for surface women workers, and latrines are provided at each installation, in addition to a few superior baths for officials. At l'Esperance and Violette collieries there are also 15 shower baths for women workers, and 40 women use them. At the Marihaye pit the dirty clothes of the workmen are washed on the premises at small cost, for this purpose a washhouse and drying-room having been erected.

This costs about $21.87 per month, and slightly increases the cost per bath. The actual time expended in bathing varies from 3 or 4 minutes to 10 minutes.

Summary of Costs

Epitomizing the tabulated results of the 13 collieries named, we find that the equipment for about 785 shower baths costs $97,777, or, roughly, $12,458 per 100 baths which is about $10,220 per 1000 men. The cost of maintenance is a little less than $973 per month, or, roughly, $122 per month per 100 baths. The total number of colliers employed at these mines when the figures were taken, i.e., in 1906, was 9570; of these 6640 used the baths daily, or about 70%. The average maintenance charged per bath was a little over ½ cent.

Taking the coal field of Liege, the average cost works out at about 0.8c. per bath taken for the 25,078 underground workmen at the mines, which is the number given in the official statistics for 1905. The total number of shifts worked were 7,604,320 and the total expenditure would be about $59,215 for the whole of the collieries of the province of Liege, the total output of coal from which was 5,874,410 tons. This gives a cost of about 1.04c. per ton, the total cost of production being $2.41 per ton. Of this the proportion of miners' baths, therefore, is 0.41 per cent.

Taking into account the interest on, and redemption of, the capital involved in constructing the baths at 15 per cent., the total cost per bath amounts to 1.4c. or 1.8c. per ton. The capital cost of erecting the baths varies from $9.73 to $17 per head, but for the last figure a very elaborate installation can be provided. At a cost of $9.73 per workman using the baths, a fairly complete installation can be provided. With 500 workmen the cost per unit may be stated as varying between $9.73 and $14.60 and taking a cost price of $11.65 per workman, and a rate of 15 per cent. for interest and amortization of capital as well as depreciation, and allowing 300 working days to the year, the capital cost works out at 0.6c. per bath.

French Practice

The provision of baths for miners in France is not compulsory, though many collieries have voluntarily provided them for the men. Mr. Redmayne, however, is informed by M. Leon (Mining Inspector for the Pas-de-Calais) that the provision will, in the very near future, be made compulsory. A rule is to be issued before the end of the year to the effect that douche baths with a dressing-room shall be constructed at the entrance to each working colliery in those cases where the number of men simultaneously employed underground exceeds 100. The scale of the installation shall be such as to allow of the workmen to bath as fast as they come out of the mine.

The douche baths will be placed at the service of the surface workers under such conditions and at such hours as shall be fixed by the mine manager. The Lens Colliery Company, Pas-de-Calais, has built at the Nos. 5, 8, 12 and 13 pits baths with 44 cabins each, but they are only used by miners coming from villages some distance away. The use of baths on the part of the miners is not compulsory, nor is it intended to make it so.

German Practice

In Westphalia the provision of miners' baths by the owners is compulsory, but the use of the bath on the part of the men is optional; practically all the workmen, however, make use of them. The building and installation of miners' baths cost about $19,460 for every 1000 workmen, the yearly consumption of water is about nine cubic metres per man, and the coal required for heating baths and buildings about one ton per man per year, the cost amounting to about 4.5c. per man per week.

J. S. Martin, I.S.O. (late H.M. Inspector of Mines) gives the following particulars regarding the washing establishments at three large collieries:

COLLIERY A—INTENDED FOR ABOUT 3000 WORKMEN

Cost of buildings	$34,550
Cost of inside fittings	19,470
Total	$54,020

This building, however, included a pay hall, office for surface and underground officials, as well as officials' bath room and lamp room, the latter alone costing $3942. The number of men employed underground is about 2600, of whom 100 work on the night shift, leaving 2500 to make use of the establishment on the day and afternoon shifts. During the changing of the shifts the men make use of the establishment, i. e., between 2 and 3 o'clock, about one-half of the men coming out while the other half change into their pit clothes.

COLLIERY B

No. 1 pit; 2000 men and boys:	
Cost of buildings	$28,700
Cost of inside fittings	10,700
Total	$39,400
No. 2 pit: 1000 men and boys:	
Cost of buildings	$15,570
Cost of inside fittings	6,570
Total	$22,140

In both cases the buildings include offices for underground and surface officials, lamp room and baths for managers and officials.

At Colliery C, employing about 1600 persons underground, the cost of maintenance, supervision and water supply is $2480 per annum, i.e., $1.54 per man employed underground.

The cost of erecting the buildings as well as maintaining them is borne by the owner. The use of the baths on the part of the men is not compulsory, but the men in the great majority of cases use them without exception, except in the Ruhr District and in Silesia.

In accordance with instructions issued by the management the workmen are obliged to bring clean working clothes with them every Monday, and to take their dirty clothes home on Saturday. If this is not done they are subject to a penalty. Special regulations do not exist for the working of the establishments; the workmen, however, mostly conduct themselves with propriety while in the building.

Canadian Coalettes

A "coalette" factory has been added to the list of industries of Fort William, Ont. Consul General John E. Jones, of Winnipeg, explains that Fort William was selected because it is here the great barge transportation companies have their wharves and coal docks and because practically all the coal coming from Pennsylvania mines is routed through the Great Lakes to Fort William.

This new $100,000 enterprise is financed by local capitalists, and has a contract with the several railroad and lake transportation companies for the coal dust or screenings collected at their dumps. The company has installed a Renfrew (plunger type) coalette machine, manufactured at St. Louis, Mo., with a capacity of 10 tons per hour.

The company has been quite successful, being able to market immediately its entire output, and is considering the installation of several new machines.

The "coalettes" find ready sale in Canada as far west as Edmonton, and are sold in Winnipeg at $9 per ton, as against $10.50 for hard furnace coal. Wholesale prices vary from $4.75 per ton for the coalettes made from American anthracite to $5 per ton for those made from Pocahontas coal. The company transacts its Western business through agencies.

Air, Electric and Mule Haulage

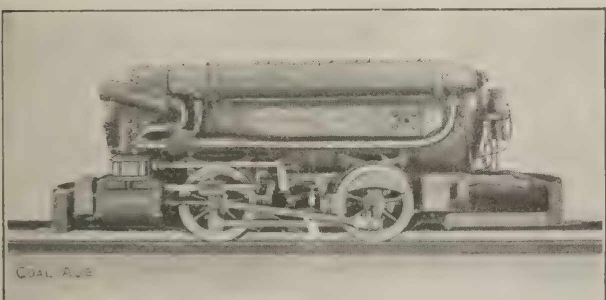
By C. B. Hodges*

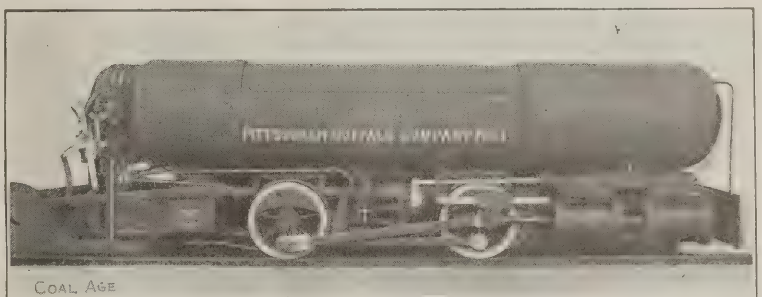
Comparisons of costs for different types of mine haulage are apt to be misleading unless carefully corrected to compensate for variance of conditions. Cost of compressed-air and electric haulage differs but little and for gathering service the mule is still a close competitor of both.

*Manager of sales, compressed-air department, H. K. Porter Co., Pittsburg, Penn.

Technical papers from time to time publish statements that it costs so many cents or fractions of a cent per ton-mile to haul coal with mules, compressed-air locomotives and electric locomotives, respectively, the generally accepted hypothesis being that the cost descends from the mule to the electric locomotive, with the compressed-air locomotive somewhere in between.

Eli T. Conner's paper, "Anthracite and Bituminous Mining," in the COAL AGE of Nov. 18, 1911, contained some figures in regard to the cost of gathering coal with electric locomotives and gathering coal with mules, and hauling it to the surface with an electric locomotive. These figures urge me to show how utterly foolish it is to compare mere ton-mile computations of the costs resulting from the use of various types of motive power without making a thorough analysis together with radical corrections to compensate for the disparity in conditions and requirements.





COMPRESSED-AIR LOCOMOTIVES FOR GATHERING AND MAIN-HAULAGE SERVICE

Comparison of Costs

The mine Mr. Conner selected as an example had a capacity of 8140 gross tons per month and the grades in the rooms were 12 per cent. He does not state how steep they were on the entries. The figures presented here for comparison are for compressed-air locomotives and mule haulage and were taken from the books of a coal mine in western Pennsylvania having a capacity of about 35,000 tons per month. The grades in this mine are variable, some of them in favor of, and some of them against the loads, and are in places as steep as 6 per cent. The capacity of the mine cars is two tons, and their empty weight 2700 lb. In the case of the electrically operated mine, the car capacity was not definitely stated, but presumably it was about 3000 lb., and the weight of the car itself about 1300 lb. A comparison of figures for the two cases is given in Tables Nos. 1 and 2.

TABLE I. ACTUAL COSTS ON THE BASIS OF 553 LOCOMOTIVE HOURS PER MONTH, OR TWO SHIFTS PER DAY, FOR A FOUR-TON ELECTRIC LOCOMOTIVE AND A SIX-TON COMPRESSED-AIR LOCOMOTIVE IN GATHERING SERVICE

	Hours		Hourly Rates		Amount, Dollars		Tons		Cost per Ton	
	Electric	Air	Electric	Air	Electric	Air	Electric	Air	Electric	Air
Locomotive runners	553	553	22½	30 5/9	124.43	168.97	4045.19	10,404.6	0.0307	0.0162
Brakemen	692	553	20	28 8/9	138.40	159.76	4045.19	10,404.6	0.0342	0.0153
Total labor					262.83	328.73	4045.19	10,404.6	0.0649	0.0315
Supplies					18.42	78.00	4045.19	10,404.6	0.0045	0.0075
Repairs and maintenance					18.00		4045.19		0.0045	
Power					20.00	117.56	4045.19	10,404.6	0.0050	0.0113
Interest 6% on $10,000 for one month					50.00		4045.19		0.0123	
Interest 6% on $5,900 for one month					......	29.50	......	10,404.6	......	0.0028
Depreciation eight years					35.42	......	4045.19	....	0.0088	......
Depreciation 10%					......	49.17	....	10,404.6	......	0.0047
					404.67	602.96	4045.19	10,404.6	0.1000	0.0578

TABLE 2. RELATIVE COST PER MILE AND DATA FOR ESTIMATE

Average haul with electric locomotive	3600 ft.
Average haul with compressed air locomotive	2100 ft.
Total ton miles, electric locomotive	2758
Total ton miles, compressed air locomotive	4138
Total cost per ton mile, electric locomotive	14.68c.
Total cost per ton mile, compressed-air locomotive	14.57c.

Working two shifts is a decided advantage to either electric locomotives or compressed-air locomotives as compared with mules, because mules cannot be worked two shifts, whereas locomotives can, thereby distributing the increased interest and depreciation charges over double the number of hours. As a matter of fact, the compressed-air locomotives at the mine cited above, only worked one shift, but the costs per hour and per ton have been held exactly the same as they actually were with the exception that the interest and depreciation are distributed over 553 hours per month and over the amount of coal that would have been gathered in 553 hours had the locomotives continued to work at the same rate which they maintained for nine hours per day and six days in the week. This was done in order to make the costs more truly comparable.

It should be observed in connection with the above figures for cost per ton and ton-mile that neither of these costs is in general an accurate basis for testing the comparative merits of the two types of haulage, particularly as regards gathering service, although the same considerations apply to a more limited extent in connection with main haulage. When gathering, the locomotive necessarily spends most of its time in collecting the trip, while the ton mileage is run up by the long haul between the point where the coal is gathered and the point where it is delivered. The expense of haulage does not increase directly in proportion to the length of the haul because the time spent in gathering remains a constant regardless of the length of the direct run. Usually if an analysis is made of the power expended and time spent in gathering and in hauling the gathered cars to the terminus, it will be

found that the strictly gathering service is the most expensive part of the work.

Necessary Corrections

Changing those items in the foregoing table which are either manifestly not chargeable to the gathering type of locomotive or else need correction, Table No. 4 is derived. The figures are for the same locomotives working under the same conditions as before, but with the engineers and brakemen receiving the same rate of pay, and with Mr. Conner's charge for power increased from $20 to $50 per month, and with the item "depreciation 8 years, $10,000" raised to $84.20 per month. The reason for changing the rate of $20 per month for power as given in Mr. Conner's paper is explained in following paragraphs.

Based on the corrected and equalizing figures of Table 4 the cost per net ton-mile would be 17.55c. for electric locomotive and 12.32c. for the compressed-air locomotive.

Mule Haulage

In the same mine where the compressed-air gathering locomotives operate, horses are used for gathering coal in another part of the mine. The coal gathered by both the small air locomotives and the horses is hauled to the foot of the shaft by large compressed-air locomotives. The cost of gathering by horses in this mine is as follows:

TABLE 3. COSTS OF GATHERING BY HORSES

	Day	Week	Cost per Ton
Nine drivers at $2.60 per day	$23.40	$140.40	
One d iver at $2.70 per day	2 70	16.20	
Total labor		$156.60	$0.0318
Stable expense		83.60	0.0170
Th rteen horses, $3250 depreciation 5 years		12.50	0.0025
Interest, 6% on $3250		3.75	0.0007
		$256.45	$0.0520

With the ten drivers, eleven work horses and two spares, 4918 tons of coal were gathered per week and hauled an average distance of 900 ft., giving the cost per ton as stated above in detail and a total cost per ton-mile of 30.6c.

The cost per ton for gathering with mules or horses in the mine to which Mr. Conner referred was as follows:

TABLE 5. COSTS OF MULE HAULAGE

			Cost per Ton
Average distance of mule haul			1200 ft.
Drivers, 250 hr. at 30c	$75.00		
Drivers, 398 hr. at 18c.,	71.64		
Drivers, 294 hr. at 19c	55.86		
Drivers, 310 hr. at 20c	62.00		
		$264.50	$0.0646
Stable boss		35.00	0.0086
Blacksmith, shoeing		30.00	0.0074
Feed		79.20	0.0193
Miscellaneous supplies		18.52	0.0043
Depreciation, 5 years		25.00	0.0062
Interest 6% on $1500		7.50	0.0018
Total		$459.72	$0.1122
Total cost per ton mile			49.4c.

The coal gathered by the mules in this mine cited by Mr. Conner was hauled to the pit mouth, an average distance of 2500 ft., by an electric locomotive.

The comparative figures for main haulage in the two mines under consideration, one using electricity and the other compressed air, are given in Table No. 6.

The electric locomotive moved the coal an average distance of 2500 ft. and the compressed-air locomotive hauled it for an average distance of 3400 ft., so the costs per ton-mile, is as follows:

For electricity: $\frac{2500 \times 4095}{5280} = 1938$ ton miles

$\frac{209.83}{1939} = 10.83$c. per ton mile

For air: $\frac{3400 \times 19{,}688}{5280} = 12{,}677$ ton miles

$\frac{386.31}{12{,}677} = 3.05$c. per ton mile

Correction for Cost of Power

In explanation of the correction of Mr. Conner's figure of $20 per month for power as given in Table 1 and increased to $50 in Table 4, it should be noted that the costs of power per ton-mile for gathering and main haulage as given in Mr. Conner's paper are as follows:

Cost for power in gathering	$20.00
Ton mileage as calculated from Mr. Conner's paper	2758

$\frac{\$20.00}{2758} = \$0.00726$ per ton mile

For main haulage, as calculated from Mr. Conner's paper:

$\frac{\$20.00}{1939} = \$0.01032$ per ton mile

TABLE 6. MAIN-HAULAGE COSTS—ELECTRIC LOCOMOTIVES AND COMPRESSED-AIR LOCOMOTIVES

	Hours		Hourly Rates		Amount		Tons		Cost per Ton	
	Electric	Air	Electric	Air	Electric	Air	Electric	Air	Electric	Air
Locomotive runners	277	277	$22\frac{1}{2}$	$30\frac{5}{9}$	62.32	84.6[illegible]	[illegible]095.10	19,687.7	0.0153	0.0043
Brakemen	346	277	20	$28\frac{8}{9}$	69.20	80.0[illegible]	[illegible]095.10	19,687.7	0.0169	0.0041
Total labor					131.52	164.66	4095.10	19,687.7	0.0322	0.0084
Supplies					2.65	......	4095.10	......	0.0006	0.0013
Repairs and maintenance					7.24	25.3[illegible]	4095.10	19,687.7	0.0018	
Other repairs and maintenance					5.71		4095.10		0.0014	
Power					20.00	80.18	4095.10	19,687.7	0.0049	0.0011
Interest on investment, 6% on $5,000					25.00	......	4095.10	......	0.0061	
Interest on investment, 6% on $8,650					......	43.25	......	19,687.7	......	0.0022
Depreciation eight years					17.71	......	4095.10	......	0.0042	
Depreciation eight years on $8650						72.83	......	19,687.7	......	0:0037
					209.83	386.31	4095.10	19,687.7	0.0512	0.0197

It will be seen from these figures that the cost per ton-mile is 42 per cent. greater for the main haulage than for the gathering service.

The costs of power per ton-mile for the same two classes of service at the mine that I investigated were:

For gathering: $\frac{\$117.56}{4138} = \$0.0284$ per ton mile

For main haulage: $\frac{\$80.18}{12677} = \$0.0063$ per ton mile

These figures show the cost for gathering with compressed-air locomotives to be 4.48 times as great as for main haulage. There are many reasons why the cost for power per ton-mile for gathering should be much more than for main haulage, but none why it should be less,

TABLE 4. ACTUAL COSTS CORRECTED FOR COMPARISON—COMPRESSED-AIR LOCOMOTIVE AND ELECTRIC LOCOMOTIVE IN GATHERING SERVICE

	Hours		Hourly Rates		Amount, Dollars		Tons		Cost per Ton	
	Electric	Air	Electric	Air	Electric	Air	Electric	Air	Electric	Air
Locomotive runners	553	553	$22\frac{1}{2}$	$22\frac{1}{2}$	124.43	124.43	4045.19	10,404.6	0.0307	0.0120
Brakemen	692	553	20	20	138.40	110.60	4045.19	10,404.6	0.0342	0.0106
					262.83	235.03	045.19	10,404.6	0.0649	0.0226
Supplies					18.42	78.00	4045.19	10,404.6	0.0045	0.0075
Repairs and maintenance					18.00		4045.19		0.0045	
Power					50.00	117.56	4045.19	10,404.6	0.0123	0.0113
Interest 6% on $10,000 for one month					50.00	......	4045.19	......	0.0123	......
Interest 6% on $5,900 for one month						29.50	......	10,404.6	......	0.0028
Depreciation eight years on $10,000					84.20	......	4045.19	......	0.0208	
on $5,900						49.67	......	10,404.6	......	0.0047
					483.45	509.75	4045.19	10,404.6	0.1193	0.0489

unless a condition when all the main haulage is up hill and all the gathering is down hill might be cited as an exception.

In all the above figures it is the ton of coal moved one mile in the desired direction that is considered. In actual service, the cars and the locomotive must be moved as well as the coal, and because the car and the locomotive must move approximately twice as far as the coal in order to get the empty cars back to the loading place, the gross ton mileage is nearly twice the net ton mileage for main haulage. For gathering work the gross ton mileage will be from four to six times the net ton mileage because in gathering cars from the rooms the locomotive must make many movements with only one car or without any cars. While doing this work the percentage of net to gross tonnage is exceedingly low because the locomotive itself forms a large part of the total weight of the moving train.

Any remaining inconsistency in the relative costs of main haulage and gathering service with the compressed-air locomotives is readily accounted for by considering the following adverse conditions of gathering as compared with main haulage: Ordinarily the gathering locomotive has poorer track than the main-haulage locomotive; a greater percentage of curves, more frequent stops and starts, and a somewhat lower efficiency, because of handling only one car at a time instead of being loaded approximately up to its capacity.

From the foregoing considerations it seems certain that Mr. Conner's figure of $20 as the cost of power for the electric gathering locomotive needs correction; more especially as this locomotive operated two shifts per day, while the main-haulage locomotive operated only one shift.

Mr. Conner's conclusion that, as it cost only 10c. per ton to gather and haul 4045 tons of coal per month with one locomotive working two shifts, and as it cost 16.34c. per ton to gather 4095 tons of coal with mules and haul it 2500 ft. to the pit mouth, there is, therefore, an advantage of not less than 4c. per ton in gathering by electric locomotives, does not seem to have sufficient support to make it generally true.

Gathering Locomotives vs. Mules

In the mine using compressed-air haulage, coal was gathered and hauled by mules an average distance of 900 ft. at a cost of 5.2c. per ton and was afterward hauled an average distance of 3400 ft. by main-haulage compressed-air locomotives at a cost of 1.97c. per ton, giving a total cost for gathering and hauling of 7.17c. per ton, a lower figure than any that Mr. Conner quotes. This figure is also slightly lower than the results achieved with compressed-air gathering and main-haulage locomotives in sections of the same mine where the gathering locomotives worked but one shift, as is shown by the following costs:

Gathering by compressed-air locomotives	6.72c. a ton
Main haulage	1.97c. a ton
Total cost	8.69c. a ton

Thus it is seen that the coal was delivered to the shaft bottom more cheaply by mules and main-haulage locomotives than by gathering locomotives and main-haulage locomotives; but in order to achieve these results with the mules it was necessary to keep the mule haul down to 900 ft. or less in order to enable the animals to gather, as they did, 41.6 two-ton cars per mule. If the mules had to haul the coal an average distance of 1200 ft., as did the gathering locomotives, and had been forced to encounter the adverse grades that the locomotives did, the cost for mule haulage would have been 50 per cent. greater, throwing the balance again in favor of the gathering locomotive. In other words, it was possible to obtain the good results that were obtained with mules in this mine only by working them in selected places under the most favorable conditions, all of which goes to show that it is extremely dangerous to draw general conclusions in regard to the relative economy of the various types of haulage unless the conditions are strictly comparable, or accurate corrections are made to compensate for differing conditions.

Conclusions

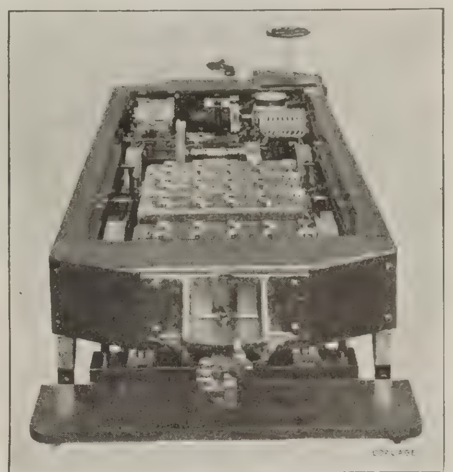
The writer does not believe that the foregoing figures in regard to the relative cost of haulage by electricity and compressed air represent with any degree of accuracy the relative merits of the two systems. The much greater tonnage handled by the compressed-air locomotives gives them a decided advantage, but there is a lamentable dearth of accurate information in regard to the relative costs of the various systems of haulage. Many of the opinions expressed in regard to relative economy are founded largely on prejudice, with little or no basis of accurate information, and a consideration of the above figures in regard to capacity and performance show, if they show anything, that the relative costs of haulage by the two systems depend more upon their intelligent installation and handling than upon either type of haulage, and that with equal energy and experience the difference in the cost of haulage by either system will appear only as small fractions of a cent. Further, they show that if the mule haul can be kept short and the grades not too steep, the mule in gathering service is a close competitor with either type of locomotive and will remain so until the general advent of the three- or four-ton mine car enables the locomotive to get more coal each time it makes a trip up the room.

Storage Battery Locomotives

The success of the storage battery equipment for electric vehicles has been so marked that it has been applied to electric cars, electric locomotives, etc. The storage battery locomotive is designed for service where a trolley system cannot be installed or is not desirable, and finds applications especially in short distance hauls at low speeds. These locomotives may be built to haul their loads or to carry them on the platform.

Advanced Mechanical Construction

The General Electric Company is now placing a storage-battery locomotive on the market. The mechanical design is in accordance with the most approved and uptodate practice. The frame consists of two steel I beam sides and two steel channel ends, carefully fitted at the joints



End View of Locomotive Truck Impelled by Storage Batteries

and held rigidly together with steel angles and heavy bolts. The end frames are faced with wood bumpers to which suitable coupling devices are attached, these latter being designed to suit the customer's cars. The cast-steel pedestal jaws which carry the journal boxes are bolted to the lower web of the side frames.

The cast-steel journal boxes are of special design and are fitted with roller bearings which ensure efficient mechanical transmission of power and so effect economy of battery current. The weight of the car is supported from the journal boxes by two heavy coiled springs.

Brake tension is effected by a screw and nut appliance, the brake spindle having a square thread on which travels a nut carrying an equalizing bar which is attached to the brake-lever system. This furnishes an efficient method of braking, as a slight exertion only on the part of the operator is required and the brakes are automatically locked in any position without the use of pawls or ratchets.

The wheels are pressed on and securely keyed to the axles. The latter are made of a special grade of steel and are case-hardened at the journals, so that there is very little wear either on the roller bearings or on the axles.

Electrical Efficiencies

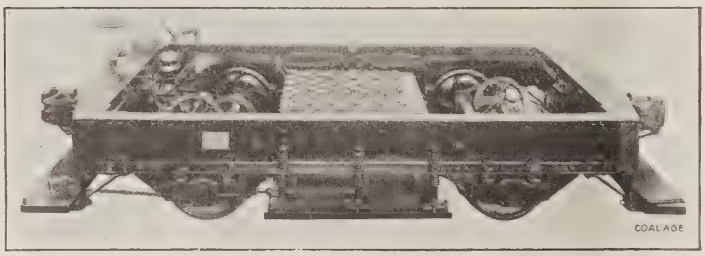
The motors used are of the automobile type designed to be operated by batteries and have characteristics that effect the maximum possible economy in the use of battery current. They have high efficiency, large overload capacity and practically sparkless commutation. The high efficiency is obtained by designing them with a small air gap and running the iron at low magnetic densities; by virtue of the latter, the speed and torque characteristics are steeper than in the case of the ordinary series motors, a feature which tends to reduce the overload which can be thrown on the battery. The armature shaft rotates in ball bearings and consequently the friction losses are light and the wear of the bearing is practically negligible.

The motors are compactly designed, yet they are readily accessible for inspection and repairs. They are also dust and moisture proof and are mounted in a cast-steel suspension cradle, one side of which is supported on bearings on the axle while the other side is spring suspended from the locomotive frame, this manner of suspension being equivalent to standard railway practice. The motor drives the axle through double reduction gearing. An intermediate shaft which is supported in the housing of the bearing and cast integral with the suspension cradle carries the intermediate gearing.

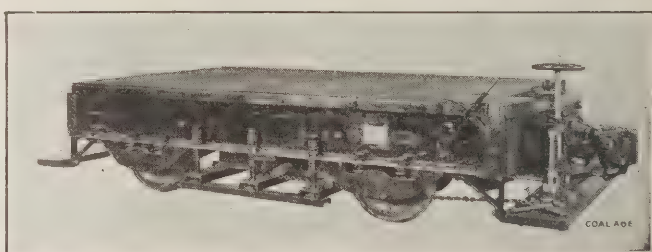
As the service required of a storage battery locomotive is ordinarily performed at low speed, the use of the double reduction gearing permits slow speeds to be obtained without any rheostat losses and, due to the large gear reduction from armature shaft to wheel tread, high tractive efforts are obtained at comparatively small current inputs to the motor. When carrying light loads these locomotives have speeds of from 4 to 5 miles per hour, while on heavy loads the speed is from 2 to 2½ miles per hour.

The storage batteries are especially designed for the service, being very rugged in construction and due to the use of specially constructed plates, have high ampere hour efficiency. The battery cells are grouped in four or more trays and are mounted in an angle iron crate which is spring-suspended from the locomotive frame.

A 20-ton Load of Castings Carried by Storage-battery Truck



Locomotive Equipped with Storage Batteries; Cover Plates Removed



Storage-battery Locomotive Complete with Iron Floor Plates

When robbing pillars the yield may be increased at least 2 per cent. by the use of posts set 3 ft. apart, tight up against the coal, to protect the stump from roof falls.

Kentucky's Coal Output

An estimate of the production of commercial coal by the Kentucky mines for the calendar year 1911, has been given out by the Chief Inspector of Mines and Director of the State Geological Survey. The estimate, which is based on returns that had been received up to Dec. 24, indicates that the output for the last year fell about 1,550,000 tons short of that for the year 1910. A number of companies had not reported for the month of November on the date named; hence the output of some important companies for November and December is estimated.

As indicated by the returns received, the output for the year was about 13,170,227 tons, the production of the respective districts being about as follows:

Western (including 1,057,000 tons estimated)............	6,800,276
Southeastern (including 566,000 tons estimated)............	4,019,545
Northeastern (including 506,000 tons estimated)............	2,350,406
	13,170,227

The total for the year 1910 was 14,720,011 tons. The returns for 1911 indicate a loss of over 1,500,000 in the western district and a loss of about 235,000 tons in the southeastern district, but a gain of about 312,000 in the northeastern region. Although the output was much less than for 1910, it exceeded the production for 1909 by 2,800,000 tons.

There were no large disasters during the year, and so far as reported the total number of fatal accidents was less than for 1910 (the 50 lives lost through explosions during the latter year being omitted from the comparison).

Notwithstanding the fact that 1911 proved rather a bad business year for the coal industry, the interest of investors in Kentucky has not flagged. The development of mines in the eastern coal field is increasing rapidly. Harlan county began shipping commercial coal in October, and is expected to become an important producer in 1912. Letcher county will become a commercial producer in 1912, and a large output is expected from it. The Survey correspondence indicates much interest on the part of capital in the western coal field also. Two reports covering a large part of this field, which with others have been awaiting publication for some time, are to come from the press by May.

Causes of Iowa Mine Explosions

By John Verner*

The mines in Iowa, which are dry but nongaseous, appear to be subject to explosions when first developed and immune when further extended. The movement of air is retarded by the greater resistance of the lengthened passageways. This results in slower feeding of coal dust and air to the explosion flame, preventing propagation beyond the point of origin.

*Chariton, Iowa.

Coal mining in Iowa commenced in a very small way about the year 1840. There was little increase in production during the following years and in 1867 the annual output had only reached 150,000 tons. From that time progress in the coal industry was more rapid and in 1883 Iowa produced 4,500,000 tons or within 500,000 tons of the combined coal production for that year of West Virginia, Kentucky and Tennessee. In 1910 the output of the Iowa mines amounted to nearly eight million tons.

Only about one-seventh of the coal produced in this state is mined without the use of powder, and the great remainder of the output, owing to the hardness of the coal and the absence of a sufficiently soft clay to permit undercutting, is blasted from the solid. In all mines producing coal in this manner the room-and-pillar method is used together with the double-entry system.

Mines Are Generally Dry

The mines are generally dry and many of them more or less dusty, but there is no provision either by law or through voluntary action on the part of the operator for the systematic artificial humidifying of dry mines. In the recent session of the Iowa legislature it was provided that "The owner, operator, lessee or person in charge of any mine shall not permit the accumulation of dust upon and along the roadways; and where the roadways are dry and dusty shall cause the same to be sprinkled at least once each week and as much oftener as conditions may require."

It is conceded, however, that the intent of this measure is to improve mine sanitation rather than to increase mine safety. The shots are prepared by the miners and are examined before they are charged, the examiners having the power to prohibit the charging of any shot they consider unsafe. The firing is done, generally by the examiners, at the end of the shift and after the miners have left the mine. The shots are set off by fuse and are fired in rapid succession.

Much powder is used and in the larger mines the daily consumption of a ton of powder is of frequent occurrence. Owing to the high cost of yardage and for other good reasons the elaborate ventilating methods found in many Eastern mines cannot be used in Iowa, but nevertheless the mines are now somewhat efficiently ventilated, although in former years their condition, in this respect, was often unsatisfactory. This condition resulted mainly from bad management but perhaps an important cause was the entire absence of firedamp, which has never been found in any mine in this state.

Explosions Are Infrequent

No explosions, causing loss of life or great destruction of property, occurred in the Iowa mines prior to 1892. In that year, on Nov. 8, the Pekay explosion occurred, killing three miners and wrecking the south side of the mine. On Feb. 14, 1893, the explosion in the Cedar mine caused the death of seven persons, but the years 1901 and 1902 proved the most disastrous in this respect. In these two years seven explosions occurred, doing much damage in the mines affected and killing 27 miners. The loss of life would have been very much greater had it not been for the fact that shotfirers were employed in all the mines, except one.

To prevent these disasters the legislature in 1902 enacted a law requiring the examination by competent persons of all shot holes before they are charged and this method has proved fairly effective, for under its application mine explosions have become less frequent, those occurring since 1902 being of comparatively little extent and showing a correspondingly decreased destructive force. During the last three years only one explosion occurred, and that a small one, which did no material damage and caused no loss of life.

A detailed description of past Iowa mine explosions would be of no particular benefit at this time, but it may be of some value to those interested in the explosion problem to have a knowledge of the conditions in some representative mines before explosions made their appearance in Iowa and about the conditions that existed in other mines, visited by explosions, before and after their occurrence.

Mine No. 1 was opened by the Whitebreast Coal Co. in Lucas County in 1876 and Mine No. 2 in 1880. The mines were dry and turned out to be large producers, measured by the Iowa standard, No. 2 employing more than 400 men during its best years. They were opened by skilled and experienced miners, much pick work was done, powder was used sparingly, the shots were well prepared and as the squib was used to fire them, the holes were firmly tamped all the way. The shots were lighted one at a time in a place and the miners did their own firing at quitting time.

Miners Change Mining Methods

In this manner the work was done for several years with satisfactory results and then a change came, first in the way of shot preparation and then in the method of firing. The miners in narrow work found that by drilling the holes 2 or 3 ft. ahead of the cut, coal cutting was made less laborious and more of it could be done in a given time. Of course, the amount of powder used was much increased by this practice, which brought with it an increase in the production of fine coal.

Then to escape the unpleasant and somewhat dangerous task of going back through the powder smoke to fire their second or third shots, the miners generally resorted to the use of fuse. To avoid cutting the latter the holes were tamped loosely with dry drilling dust. In the meantime the mines had become quite extensive, with the workings a considerable distance from the shafts, the air courses were much obstructed by falls and otherwise, the ventilation was unsatisfactory and the presence of black-damp became noticeable, especially on the returns.

The mines remained dry and the accumulation of dust increased to such extent that great clouds of it were raised by men and mules traveling on the haulage roads. Occasionally a water car, discharging its contents through a hole in the rear end, was used to wet the roads between the rails, but this was not done through any fear of a possible explosion, but to abate somewhat and for a little time the existing dust nuisance. Such conditions existed for years and continued until the mines were abandoned. Yet hundreds of heavily charged shots, tamped with dry coal dust, were fired daily by the miners at the end of the shift, in probably less than ten minutes, and it is a conservative statement to say that fully 5 per cent. of these shots blew out their tamping and that at least another 10 per cent. were more or less ineffective, yet nothing occurred to show that there was danger in the presence of the great accumulations of dry dust.

A Mysterious Difference between Old and New Mines

It might be said that the dust in these mines was not of an explosive nature and it would be difficult to disprove this, were it not for the fact that an explosion occurred in Mine No. 3. This mine was opened adjacent to No. 2, connected with the latter, which was still in operation and which in turn was connected with the workings of No. 1. The first explosion in Lucas County occurred in No. 3, a new mine, well ventilated, with roomy roads and air courses containing little dust, and worked under the same methods that had been used for years with impunity in the older mines. This happened twelve years after the opening of No. 1 and after several million tons of coal had been produced from the same seam.

The Pekay mine, located in Mahaska county, was opened in 1891. A number of the men, who had worked for years in Mines 1 and 2, came to the new mine and brought with them the practice of blasting in use in those mines. But they soon discovered, as in Whitebread No. 3, that the practice found safe in one mine under apparently like conditions may be extremely dangerous in another, for a violent explosion occurred in the Pekay mine while its workings were yet within a few hundred feet of the shafts.

I examined the mine shortly after the explosion and found that although several kegs containing powder were exploded in different places, the presence of coal dust undoubtedly was a large factor in extending the explosion through all the south side and part of the north side of the mine. The disaster naturally made the men more careful in placing their shots, but aside from that no other preventive measures were taken and it appeared that their absence brought no harm, for several years passed and the mine remained apparently safe.

A Similar Increase in Safety at Pekay Mine

In 1899 I was assigned to the 2d Iowa inspection district in which the Pekay mine was located. I found the mine in an unsatisfactory condition especially with regard to ventilation, the air courses being much obstructed by falls of roof and otherwise throughout their entire length. The south workings still remained dry and dust accumulations had increased with the mine's extent with no provision for the systematic sprinkling of the dust in the dry parts of the mine.

The miners evidently had come to the conclusion that there was no further danger from explosions, for the shots were tamped with dry dust and very rapidly fired by fuse at the end of the shift. I found that as many as five holes, tamped loosely with dry dust, had been fired almost simultaneously in one room without the slightest evidence of bad effects. In addition to all this, blown-out and ineffective shots were a daily occurrence. The dust contained in the mine seemed to have lost its power to do harm, for the mine was worked safely for years under above mentioned conditions and until it was abandoned 10 years after the explosion.

A New Mine and Several Explosions

In 1899 and 1900 the Whitebreast Fuel Co. opened Mine No. 4 in Lucas county, a few miles west of the location of Mines 1 and 2. The new mine was dry and there was some dust. Shot examiners passed judgment as to the safety of the shots prepared by the miners and fired those accepted after the day force had left the mine. But these safeguards, while removing the possibility of great loss of life, did not prevent explosions, for in January, 1901, a violent explosion occurred, killing the shotfirers, followed by another a month later of still greater destructiveness. In January, 1902, a third explosion wrecked a part of the mine and killed the shotfirer.

I had charge of this mine as inspector and examined it carefully immediately after each explosion. I found that explosion No. 1 was caused by improperly prepared and overcharged shots, that No. 3 was caused the same way and that in No. 2 the two shots in the room where this explosion started, did their work fairly well and were not overcharged and that all three explosions were propagated and extended by the presence of dust.

Three explosions in one year was plain evidence that the mine was worked under extremely dangerous conditions and that a decided change in the methods used was necessary for the better protection of life and property. But there was no change. The miners and the mine management were well aware that the danger was due primarily to the use of powder but they concluded that it must be used or the coal left unmined.

No sprinkling or spraying system was installed to keep the dust in moist condition, because it was generally realized that it would be of little practical value in rendering harmless the fresh dust at and near the working faces, that was produced daily in comparatively large quantities by blasting and the handling of the shattered coal. But there was the expectation that the danger would become less threatening in the future, and this expectation was based upon observation of conditions in other mines and the belief that increased extension of the mine would decrease the possibility of an explosion.

Whether this faith in future events was fully justified or not, the fact remains that no further explosions occurred in this mine, although it continued in operation for six years after the last explosion and remained dry until the end, with dust accumulations increased in proportion with the mine's extent, and with no perceptible decrease in the number of blown-out or ineffective shots.

Two of Three Factors Are Constant

In the two mines named explosions occurred only during the first two years of their existence. What, then, was the cause of their disappearance and continued absence during the remaining years of their operation? It has been found that only three elements are necessary in the make-up of a dust explosion—air, combustible dust and flame. These elements were present in those mines when the explosions in them occurred, but they were likewise present afterward, with no noticeable difference in the condition, quality and quantity of the dust, with dry coal dust used for tamping in the Pekay mine until the last, with the continued abundance of flame at shotfiring time and with no appreciable decrease in the number of blown-out shots.

The only apparent difference in mine conditions was the constantly increasing distance between the live workings and the shafts, longer and less open air courses, and less satisfactory ventilation. At first glance it appears to be more than doubtful that this difference in distance, etc., was a factor in preventing further explosions, but a careful review of the whole situation not only removes that doubt, but brings the conviction that their continued absence must have been due, in some manner, to the change in the conditions named.

A dust explosion in a mine is started and propagated through intense combustion of the available fuel, and intense combustion requires intense draft. Many, however, believe that this has no application in a dust explosion, and that propagation is accomplished by the flame striking into the dust cloud which has been driven ahead of the explosion by the latter's force. It is a complicated theory and the assumed process appears unnatural.

If the dust is driven ahead of the explosion, the same is true of the air, and with dust and air receding at an equal ratio with the flame's advance, it seems impossible to maintain sufficiently intense combustion to produce explosive results. I believe that the laws applying to a mine fire apply with equal force to a dust explosion in a mine, and that intense draft, which is such a powerful factor in starting and spreading the former, is even more potential in starting and extending the latter, for in a mine fire such draft becomes a destructive agency mainly through chemical action, while in a dust explosion its power is exerted both in a chemical and physical way by carrying not only the oxygen, but also the fuel to feed and enlarge the explosion's flame.

The Insucking Theory

Abel says: "As the explosion originates and as it progresses, the motion of the air is such that particles of coal dust must be whirled up into it." Mallard and Le Chatelier conclude that "the propagation appears to be effected by the internal movements of the air instead of by conductivity or radiation." Peckham and Peck are more definite and declare "it is a draft carrying a thick cloud of dust that is dangerous," and the correctness of their view is proved by the facts brought out in the investigation of the Delagua and other explosions.

In fact, every extensive dust explosion has furnished good circumstantial evidence of the presence of intense draft opposite to its advance, evidence that is further strengthened by the direct testimony of credible men, who were caught in explosions, thrown to the ground by the inrushing air, felt the explosion's heat pass over them immediately after in an outward direction and who lived through the ordeal to give their experience.

If draft is recognized as an indispensible factor in a dust explosion, it follows that, with other conditions the same, the character of draft facilities in a mine may be considered the deciding influence between safety and danger. All the Iowa explosions referred to above started within 1200 ft. from the shafts, and the entries leading from the shafts to their starting points were roomy, of fair height and clear of obstructions. Draft facilities were consequently good and explosions occurred.

But as the workings moved further and further from the shafts, as the entries and air courses increased in length and became obstructed in various ways, draft facilities were impaired correspondingly and explosions ceased to occur. A fire of a given size burning in the furnace in a new mine produces a certain amount of draft. To maintain this draft unimpaired as the workings of the mine are extended, the fire must be increased in proportion; with the fire kept at its original size, the draft decreases with the mine's extent.

Under this law the heat of certain shots fired in the Pekay mine and in Mine No. 4, while these mines were yet of small extent, was sufficient to cause a draft strong enough to convey to the flame the required amount of air and dust to start an explosion, but as the distance between the workings and the shafts increased, the same heat of like shots under otherwise different conditions was insufficient to cause a draft of adequate force to furnish the vital means for the production of explosive results.

Draft and Draft Facilities Control Explosions

The established proof that draft and draft facilities are controlling factors in a dust explosion will have an important part in hastening the definite and final solution of the explosion problem. It will materially assist in the right adjustment of matters about which there is now much doubt and controversy. It will furnish the explanation for the great scope and destructiveness in mines of the Marianna and Monongah type. It will clearly show why the presence of moisture cannot be depended on to stop an explosion under way and why the danger from dust explosions can only be successfully resisted through the concentration of efforts against it at their possible starting points.

Coal Mine Ventilating Equipment

By W. M. Weigel *

The Capell type of centrifugal ventilator embodies a number of distinctive features. This is the fourth article of a series dealing with mechanical ventilators.

*Associate professor of mining, Pennsylvania State College, State College, Penn.

The Capell type of fan is used to a great extent in the bituminous districts of Pennsylvania. It is usually of smaller diameter than the Guibal design and operates at a correspondingly higher rotative speed. The entire fan and casing are constructed of steel plate and iron, and the incasing spiral expands more rapidly than in the Guibal type, thus making the area at the cut-off proportionately greater.

In the original form of Capell fan the wheel had two sets of blades. The outer set, as in the ordinary fan, extended from the circumference of the inlet to the rim of the wheel, and curved backwards from the direction of rotation. The inner set, equal in number to the outer, extended inward nearly to the center of the fan and projected a short distance into the inlet opening. These projections were bent forward to draw the air into the fan and deliver it through the ports, or openings in a cylinder separating the two sets of vanes. The tips of the inner blades were located about halfway between the inner ends of the outer blades. Fig. 2 shows the shape and position of the blades and the openings between the two sets.

Recent Design

In the modern form of this fan, the inner cylinder with ports is done away with. The details of a fan wheel built by the Capell Fan and Engineering Co. are illustrated in Fig. 3. The main blades extend inward to about halfway between the circumference of the inlet and the center of the wheel and their inner ends project out into the fan drift in the form of scoops. Three short blades are placed between each pair of main blades and, as shown, are of a length less than the distance from the circumference of the inlet to the outer circumference of the wheel. Their tips do not extend to the circumference.

All the blades curve forward in the direction of rotation. A small auxiliary blade, called a tail wing, is introduced as shown in the illustration, at the back of

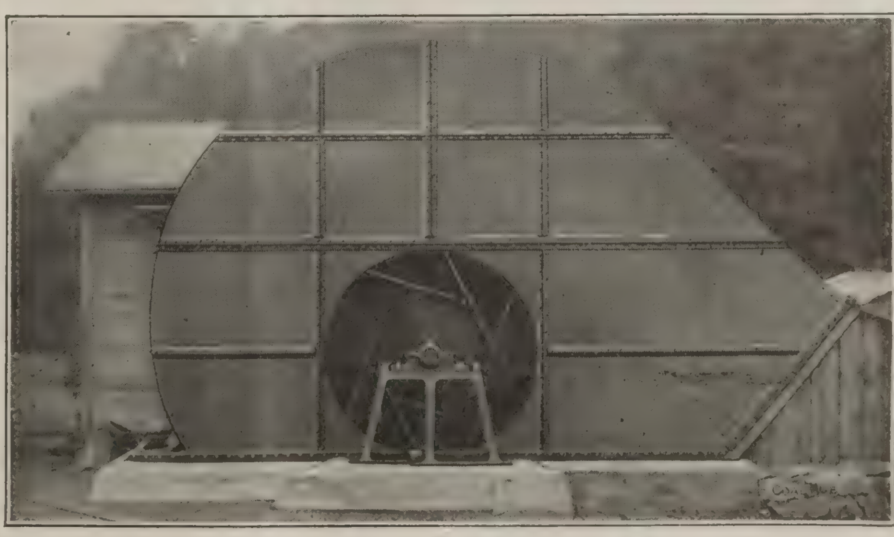


Fig. 1. 12-ft. Beard-Stine Fan, Patton, Penn.

the main wing, its object being to decrease the area between the outer tips of the blades and hence cause an increase in the velocity of the escaping air instead of permitting an expansion of the air at this point. Fig. 4 shows the outlines of the wheel and casing of an 11 ft. x 4 ft. "double inlet" fan arranged for either blowing or exhausting. Table 1 gives the results of a test of a 16 ft. x 8 ft. fan at the Sterling Mine, Fayette Co., Penn.

Modern Steel Plate Fans

Many forms of fans have been introduced in recent years which are neither of the strictly Guibal nor Capell type, some combining distinctive features of both, some resembling one more than the other and some built upon entirely new lines.

A general view of a Beard-Stine fan, made by S. B. Stine, Osceola Mills, Penn., is shown in Fig. 1; the housing being arranged for blowing into the mine. This form of fan is distinguished by the shape of the blades and the spiral casing of the Guibal type. All parts except

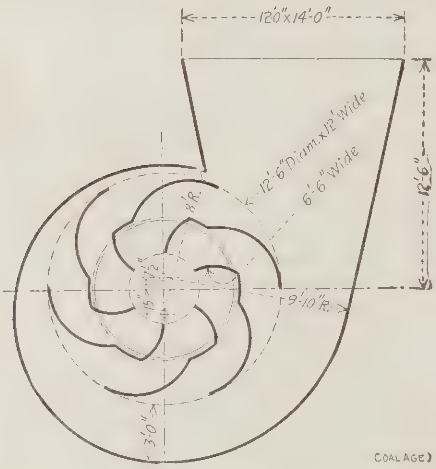

Fig. 2. Capell Fan

the foundation are made entirely of steel or iron. Fig. 5 shows the details of a portion of the fan wheel. The radius of the inlet is a little greater than half the radius of the wheel.

The steel plate blades, of which there are eight or ten, start at the circumference of the inlet, making an angle of about 30 deg. with the tangent, and curve forward in the direction of rotation until they assume a radial direction about midway in their length and continue in a radial line from here on to the tips. The blades are fastened at their center, by two angles, to a steel plate web which is secured between the two halves of the double conoid of cast iron that forms the hub. The inner corners of each blade are also stayed from the rim of the hub by means of round iron rods. This construction leaves the inlets free and unobstructed.

The blades are inclosed on the outside by annular steel disks, or cheek plates. The width of the blades is the same at both their inner and outer ends. This fan is always built with an inlet opening on each side; the curved surfaces of the hub serving to deflect the air currents into the blades.

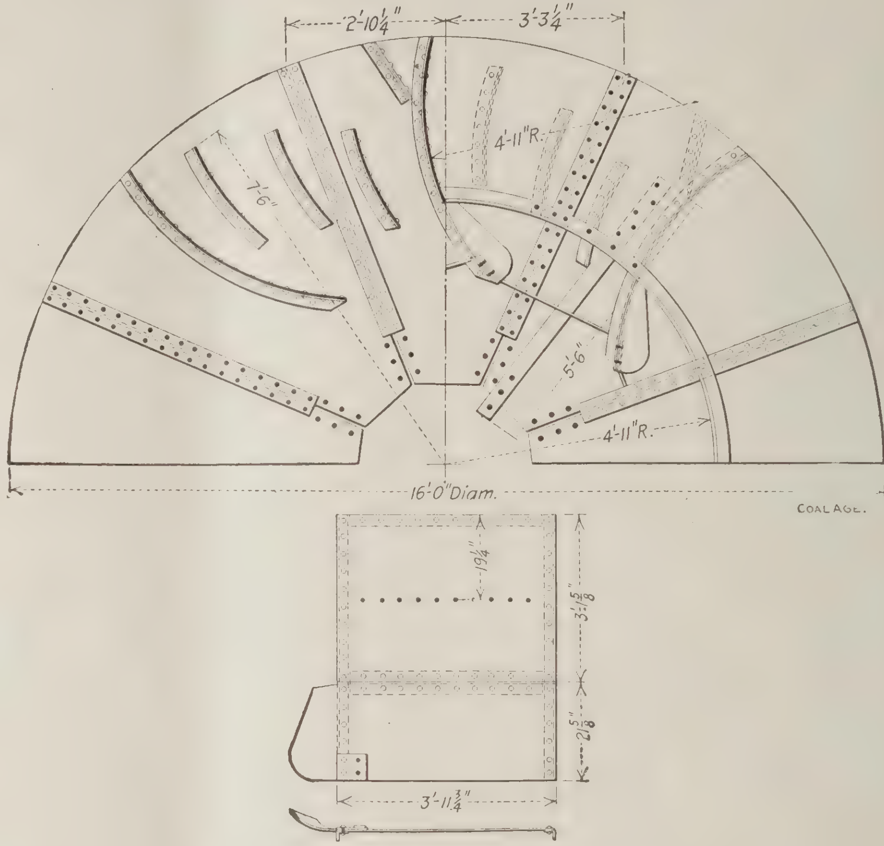

Fig. 3. Details of Capell Fan Wheel

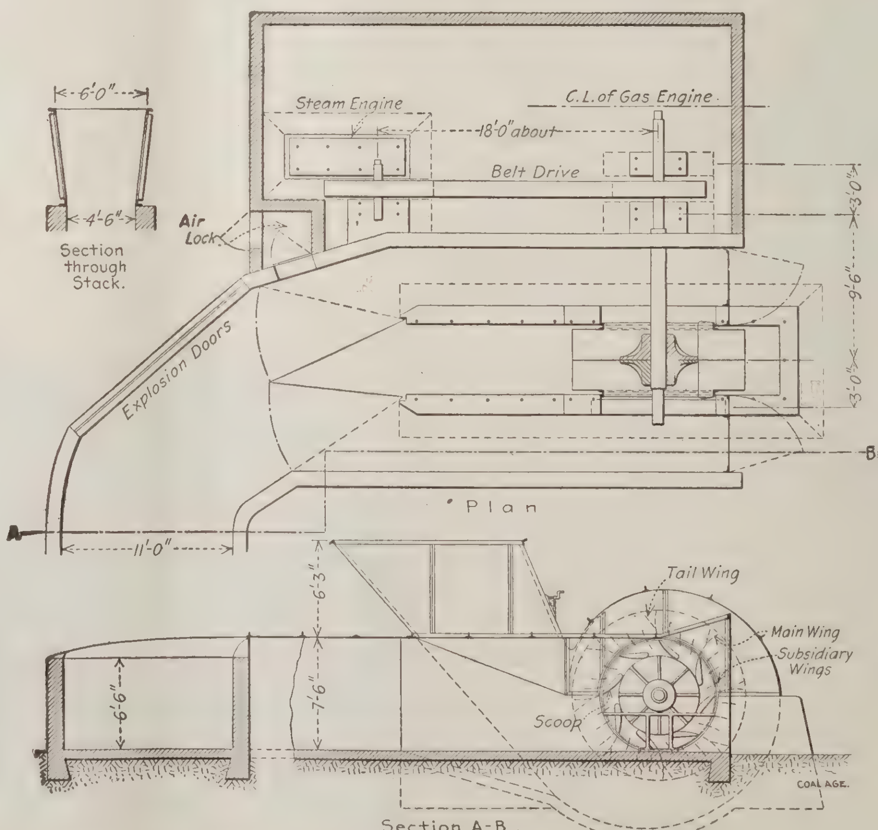

Fig. 4. Capell Fan and Housing, Showing Reversible Setting

Allis-Chalmers Fan

Table No. 2 gives the results of a test of a fan, built by the Allis-Chalmers Co. for the Lehigh Valley Coal Co., at Wilkes-Barre, Penn.

The Allis-Chalmers Co. has for some years been building large centrifugal ventilators, up to 35 ft. in diameter. These fans are in some respects similar to the Beard-Stine fan, notably in that they are always of the double-inlet center-draft type and the blades are supported by sheet-steel arms or web plates, clamped between two cast-iron centers, so shaped as to present the least possible resistance to the air as it enters the fan.

The sides of the fan are inclosed from the periphery of the intake to the periphery at the blade tips, with the idea of preventing loss of air due to clearance between the fan and the casing and also of securing a rigid form of construction. The casing is usually of steel plate, reinforced by angle iron.

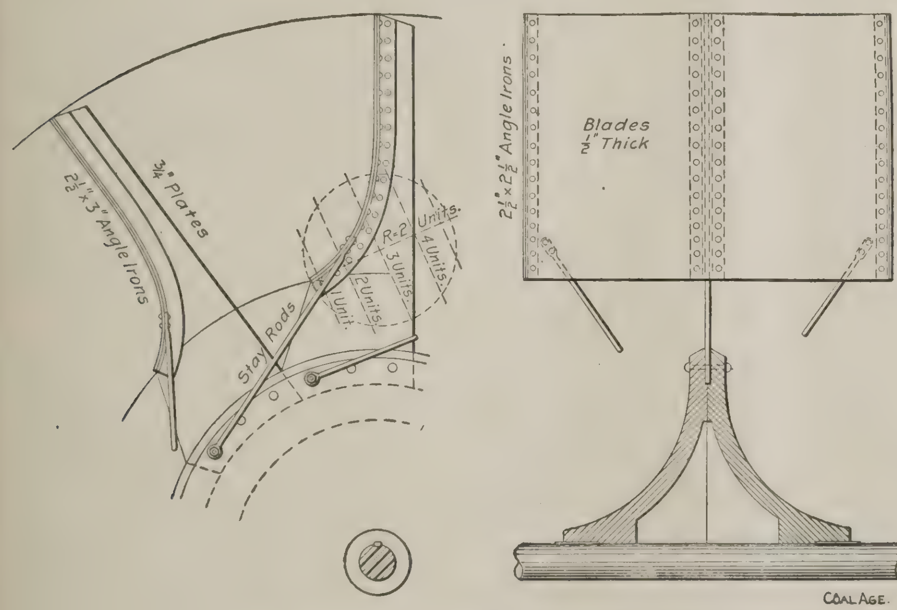

Fig. 5. Details of Beard-Stine Fan

TABLE 2. TEST OF 28 FT. FAN, "HENRY COLLIERY," L. V. C. CO., WILKES BARRE, PA.

Speed, R.p.m.	W. G., Inches	Quantity, Cu.Ft.	Horsepower on Air	I.Hp.	Efficiency	Barometer, Inches	Temp. Fahr.
25	0.4	150,000	9.454	15.45	61.19	29.36	48
50	1.2	292,000	55.214	93.72	58.90	29.36	48
75	3.0	476,000	225.020	317.80	70.80	29.37	50

Outer diameter of fan........ 28′ 0″
Inner diameter of fan........ 12′ 6″
Length of blades........ 7′ 9″
Width of blades........ 7′ 8″
Expansion of casing at cut-off........ 6′ 6″
Double intake area of fan........ $2\ (0.7854 \times 12.5^2) = 245.4$ sq.ft.
Fan drift { east side, area, 120 sq.ft. / west side, area, 121 sq.ft. } .... total area, 241 sq.ft.
Shaft '2x12, a ea 144 q. ft.
Single Corliss engine, size, 24″x48″, direct connected.
Explosion doors arranged to give a 3-in. W. G. at 75 r.p.m.

The efficiencies given above are the combined efficiencies of the engine and the fan, which materially lowers the result at these speeds below the normal working speed (75 r.p.m.) because of the increased friction ratio. Assuming 90% engine efficiency at 75 r.p.m. the power delivered to the fan was 286 hp., making the efficiency of the fan alone at this speed 78.67 per cent.

Coal Workers' Disputes

Records just made of the time required for deciding cases brought before the Anthracite Conciliation Board, the arbitration tribunal established by the Roosevelt strike commission for settling differences between hard coal mine-workers and operators, show great promptness in reaching decisions.

Altogether one hundred and ninety-three grievances have been presented. Two are now pending, and one lapsed without any decision. The time required to reach decisions in the remaining one hundred and ninety is shown as follows:

Decided on the same day as presented, 3; decided in less than one month, 24; decided in between one and two months, 46; decided in between two and three months, 17; decided in between three and four months, 17; decided in between four and five months, 11; decided in between five and six months, 9; decided in between six and seven months, 11; decided in between seven and eight months, 9; decided in between eight and nine months, 3; decided in between nine and ten months, 9; decided in between ten and eleven months, 4; decided in between eleven months and a year, 6; cases not decided within a year, 21.

As all decisions of the Board are retroactive, postponements cannot mean a money loss to the mine-worker. If it is decided that he is entitled to higher rates for certain work, he receives back pay from the day on which his grievance was filed.

United Mine Workers' Convention

Special Correspondence

The miners have indorsed Socialism and repudiated the National Civic Federation by constitutional amendment. Future national elections and conventions are to be held biennially. Wage contracts were approved as presented by committees.

A Socialist Victory

Socialists in the convention of the United Mine Workers of America won a decided victory when they succeeded by a large majority in amending the constitution of the organization to permit it to indorse the Socialist party. The clause in the constitution forbidding the miners to take any political stand was stricken out by the amendment that was adopted Jan. 22.

The convention already had gone on record as favoring government ownership of all industries, but a resolution indorsing the Socialist party as the party of the working classes was voted down as being contrary to the constitution and a substitute declaring the "miners should unite on the political as well as industrial field," was adopted.

The preamble to the constitution also was amended to read that the miners are entitled to "full value of their toil," instead of to "an equitable share."

Biennial Elections and Conventions

Alarmed by the constantly increasing expense of conducting the affairs of the mine workers, leaders of the organization pressed to passage a constitutional amendment that officers shall be elected every two years instead of every year after 1912.

Elections have cost the miners $200,000 each in recent years, according to the announcement of the constitution committee. This committee recommended also that the national conventions be held biennially. The conventions are held at an expense of $7000 per day and seldom are of less than three weeks' duration.

Former President Thomas L. Lewis attempted to have the question of biennial election submitted to a referendum vote, but failed by a vote of 418 to 376.

Wage Scales Approved

Demands for wage increases of 10c. a ton for bituminous coal and 20 per cent. for anthracite coal were indorsed by the convention. Representatives of the bituminous miners arranged to present their proposed new wage contract to the operators of Indiana, Illinois, Ohio, western Pennsylvania and West Virginia, Jan. 25. The joint conference of the anthracite miners and operators will be held in New York, Feb. 27.

The principal provisions of the draft of a new contract for the bituminous miners, submitted to the convention by its scale committee, were approved without change. They are:

Flat 10c. a ton increase in wages for pick and machine mined coal, run-of-mine basis.

Twenty per cent. increase for day labor.

Working day of seven hours "at the working place."

Five hours to constitute work day on Saturday.

Wage contract for period of two years, beginning Apr. 1, 1912.

In regard to the anthracite field, a recommendation that the demands of the tridistrict convention, held at Pottsville, Penn., Oct. 31, 1911, be made a part of the demands of the convention was passed. The demands of the anthracite district, in brief, follow:

A one-year contract.

A workday of not more than eight hours.

A 20 per cent. increase of wages over those awarded in 1903.

A minimum scale of $3.50 a day for miners, and $2.75 a day for laborers engaged in construction work.

Coal to be mined and paid for by the ton of 2240 lb., wherever practicable.

Election Fraud

Investigation of fraud in an election of national officers of the United Mine Workers of America is to be made by the executive board of the organization.

After the report of the committee on officers' reports had been made to the miners' convention, stating that "the person guilty of having stolen" the votes of 40 local unions of Illinois, cast in the election of 1910, had not been identified, a resolution was adopted instructing the executive board to make inquiry "with the purpose of uncovering the thief."

Bituminous-coal operators and miners of the "central competitive field," comprising Illinois, Indiana, Ohio and western Pennsylvania, arranged to meet in a wage conference, Jan. 26. This conference was to have been held Jan. 25, and no reason for the postponement was forthcoming from President White. It was announced that the three original states to the agreement—Pennsylvania, Ohio and Indiana—will caucus together, and that Illinois and West Virginia would not be permitted to enter these caucuses, although these two states would not be barred from participating in the discussions of the conference. It is understood that if a wage contract is negotiated it will be accepted as standard in the other bituminous districts.

Joint Scale Conference

A "courtesy" victory was won by the miners at the first day's session of the joint conference of operators and miners, when it was agreed to permit the executive officials of the miners to attend the sessions.

Great interest was manifested, because it was the first time since 1906 that the central states were represented, thus presenting a united front to the equally solid array of the miners' delegation.

It was not until the afternoon session that the joint conference formally organized by electing J. C. Kolsen, president of the Indiana Bituminous Operators' Association, chairman; Edwin Perry, secretary-treasurer of the miners' organization, secretary, with C. E. Scroggs, of the Illinois association, associate secretary.

President John P. White, of the miners, read the demands as they had been ratified by the convention, and these were not discussed. After the adjournment of the conference the operators of the four states met separately and re-wrote the miners' scale demands. The result was a parallel of the miners' document, and its provisions, in part, read as follows:

All coal be paid for on the lump or mine-run basis as preferred.

A flat 10c. per ton decrease, dead work to be paid for at a corresponding decrease.

A uniform day of nine hours at the working place.

Eight hours to constitute a day's work on Saturday.

This contract shall be entered into for a period of four years.

Constitutional Amendment

The charge by John Mitchell, former president of the United Mine Workers, that the resolution demanding he resign from the Civic Federation, or leave the union, was adopted by a convention that was packed against him, was met by the national convention of miners with an amendment to the constitution prohibiting members of the union from being members of the Civic Federation. The amendment was adopted almost without discussion.

Under the constitution as amended, a mine worker cannot be affiliated with the federation in any way whatever. The amendment reads as follows: "Mine managers, top foremen, operators, commissioners, and persons engaged in the sale of intoxicating liquors, or members of the Civic Federation, shall not be eligible to membership."

Delegates from West Virginia, Alabama, Tennessee and Kentucky met to formulate a request for the miners' organization to take steps to extend the union in these states.

COAL AGE

Equitable Taxation

The people of Scranton have for many years endeavored to find a satisfactory solution for the perils and loss of capital resulting from the instability of the foundations under their city. The means suggested for protection have been a matter of interest to every coal-mining man, east and west, and especially in the anthracite region. It appears that the Board of Trade and its energetic secretary, M. K. Edgar, and perhaps the operators also, who are busily engaged in knocking out the props below the city, have concluded that all the anthracite operators are interested now to such a considerable extent that they should supply the funds so badly needed for the city's welfare.

At a meeting of the Scranton Board of Trade, January 15, a committee reported that the coal mined should be taxed to create a fund for safeguarding the surface against settling. This report was adopted and President H. C. Reynolds will appoint a committee of 15 to act in conjunction with the taxation and legislation committee in devising a law to be presented at the next meeting of the legislature.

The heads of the big coal companies as well as the independent operators in all parts of the state will be consulted by the committee, and it is intended to hold a convention in Scranton some time during the summer, at which the various cities and counties in the coal belt will be represented and to which the coal companies will be invited to send delegates.

Without awaiting the result of this conference, whereat the delegations will receive the alluring hospitalities of the business men of Scranton, we venture to forecast that there will be no result but disappointment and abdominal repletion as an outcome of the meeting, because many coal companies in the anthracite region are not in like difficulties to those working near Scranton, and even if they are, their obligations of surface support are not equal.

It is a safe assumption that those who are mining coal which jeopardizes only their own property or which lies too deep to create apprehension of surface destruction will not favor the imposition of such a tax. Nor will those companies favor it who own the houses jeopardized or who operate where the houses they must support are relatively cheap, because if the tax is to be adequate for such universal support, then it is sure to be excessively burdensome. Nor again will operators who have been careful to obtain leases and coal ownerships which are free or even noncommittal as regards surface support, be likely to range themselves side by side with those who have agreed to leave large pillars.

It is the embarrassed man who first suggests "we will all have one purse," and we have it on good authority that of such a one we should beware. The law maxim that the buyer should take care of himself is a maxim founded on medieval standards of right. It may need modification as far as the seller is concerned, but we are sure that the maxim should apply as regards third parties. If the buyer does not guard himself by buying only such coal as is situated in places where dwellings are not likely to be built, or where the coal is deep, he is to blame. If he does not secure surface as well as coal, or does not have a clause making the destruction of the surface his proper privilege, then the regrets are his; he must foot the bill. Some Scranton operators would lay that burden of the negligent, in equal part on the back of the prudent buyer of an adjacent property who has laid out his "good money" for his own protection.

The same argument applies to a level tax on coal for the protection of the miner. There is little doubt but what the operator with gas and bad roof and a dust potent for mischief, would not hesitate to advocate the spread of risks over the whole industry by an indemnity fund continually replenished by a tax on coal. But such a provision would be manifestly as unfair as it would be to force the use of safety lamps where gas is un-

known; or to compel water cars in mines where the workings are naturally saturated.

When a coal property is bought, the proneness to accidents goes with it. It would be wrong to put as great a tax on a mine working a seam exposed to the surface on all sides, as is placed on a mine working a deeply sunk bed. The gas, dust and roof conditions are all different and a well conducted mine in the latter case might be less safe than a badly managed mine in the former.

The Case Against the Canary

The physiological data regarding animals of every kind is steadily growing, but is still incomplete. If we are not mistaken, the blood content, the amount of hemoglobin it contains, the percentage of carbon dioxide in the expired air, the number of complete breaths per minute and the volumes of normal respiration and of residual air, have not yet been investigated for the more important forms of animal life.

But Miss Florence Buchanan has contributed to our knowledge, many interesting facts concerning respiration and pulse beats, and from these, some estimates may be formed as to the relative resistance of animal life to such gases as saturate the blood to the exclusion of oxygen. From them we may discover whether there is not some animal which will have a more suitable resistance to carbon monoxide than the extremely sensitive canary.

It is a conclusion borne out by measurements, that other conditions being equal, the amount of heat demanded by any animal which maintains an even temperature depends on three causes, the temperature it maintains, the covering by which it is protected and the size of the animal. A large animal needs to generate less heat in proportion to its bulk than does a small one because it exposes a smaller surface to the air for each unit of weight.

It consequently "burns" less carbon, if that expression be permissible in describing a flameless combustion. The product of this combustion is carbon dioxide, which passes off with the breath. Miss Buchanan shows that a canary weighs 20 grams and makes 11.7 grams of carbon dioxide per hour for each kilogram of its weight. A guinea pig weighs 300 to 500 grams and delivers 1.8 grams of dioxide, whereas a man weighing 20,000 to 100,000 grams emits only 0.6 grams of the same gas in one hour, for each kilogram the scales register. It is easy to see that the canary must inhale a larger quantity of air though whether the proportion to that intaken by man is in the ratio of 11.7 to 0.6 per kilogram of their respective weights we cannot say because we are not informed as to the proportion of carbon dioxide in the expired gases.

Miss Buchanan somewhat tantalizingly evades the points which are most interesting to us. Instead of blood content, she gives us two data both less conclusive, but both highly suggestive. The canary has a heart which is 1.04 per cent. of the whole body weight. The guinea pig's heart percentage is only 0.40; the percentage for man is 0.59.

While there is this small difference in the proportionate heart sizes, there is a large and important difference in the rapidities of pulse heat. The canary's pulse beats 1000 times per minute, the guinea pig's frequency of pulsation is 300 while the ebb and flow of blood in man occurs only 70 times per minute.

If hemoglobin in an animal is proportional to blood content, and blood content, proportional to weight, and moreover, if the proportional saturation of the blood is equal to the product of the size of the pump actuating that blood multiplied by the number of strokes, then it is clear that the canary, guinea pig and man will absorb roughly in proportion to 25, 3 and 1, if the arterial system is presented with an equal quantity of gas through its recognized vehicles—the lungs. It is not permissible, however, to accept any such conclusion offhand. But it is interesting to note how closely these ratios parallel those of expired carbon dioxide.

To what conclusions does this argument lead? Perhaps to this, that an animal approaching a guinea pig in size and pulse-rate is the best animal to use for protective purposes in mine-rescue work. Such an animal would give a factor of safety of 3 provided that it were active in a like degree to man. It might be suggested tentatively then that the red squirrel, a hardy, active, perching, light and readily acquired mammal is to be preferred to the canary because while equally available in every way, it may in all probability have a more desirable resistance to blood saturation.

There will be many who will say that a factor of safety of 3 is inadequate, that a man who hurriedly climbs over falls and under dislodged rock, who carries loads and does many kinds of work, will breathe so heavily that he will need a larger factor for protection. Moreover he not only has to go in, but to come out, and his return will reduce the margin of safety to much smaller limits. There is some justice in such a contention, but it is to be hoped that a safety factor much nearer 3 than 25 will be ultimately adopted especially for those whose return is easy, who, while long in advancing can retrace their steps in a relatively short time.

It must be remembered that rescue work is not like other work; it is an heroic form of labor and nearly all rescue men will refuse to listen to a warning which simply declares that the atmosphere is so unhealthy that if inhaled for a few hours it will cause nausea, drowsiness and headache.

Comminution of Dust

Herr Belger at a meeting of the North of England Institute of Mining and Mechanical Engineers, on Dec. 9, 1911, started a new mode of attack on humidification. The conclusions he draws are interesting, if true, but it is pertinent to point out that the experimenter omitted to submit his specks of dust to the action of dry as well as to that of moist air. As physiologists and psychologists would express it, he provided no "control." He might then have discovered that disintegration was at least as rapid in dessicating air as in air which maintains the moisture of the coal.

Three specks of coal dust, the biggest not exceeding $\frac{1}{500}$th of an inch, and the smallest one-fifth as large, were kept at an even temperature of 88° F. in moist air. In a week the three specks had become eleven, and after two weeks these had become so comminuted they could not easily be counted. Herr Belger suggests that the practice of watering mines might result in such excessive comminution as to increase the dangers it was sought to avoid. It might be added, however, that in all probability dust, as it ages, may not only become finer, but also at the same time grow less readily combustible.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Sealing off a Mine Fire

[*In the Jan. 20 issue of* COAL AGE, *the editorial foreword called attention to the importance of having in mind a predetermined plan for immediate use in case of a serious mine fire. An invitation was extended readers to discuss the question, and the response has been gratifying. The general problem presented for consideration deals with a fire that has gotten beyond control, and that is located at the face of a pair of entries. The principal question is: Shall the first brattice be placed on the intake airway, or on the return side of the fire? The replies received are interesting and should result in bringing about a better understanding of the subject. Some of the letters from our readers follow, and all others who have not yet contributed an opinion are invited to do so.*—EDITOR]

Letter No. 1—I have had considerable experience in mine fires, and have only found it necessary in one or two cases to shut them off.

I close the intake first. This gives us a better opportunity to close the return. By closing the return airway first, the smoke is forced into the intake and fills it so completely that you cannot get so close to the fire on the intake side.

Of course, it is wise, if you have plenty of help, to work at both intake and return and try and close them as near simultaneously as possible, although it is not always practicable to do so. However, I have always found that one must be governed by circumstances under any and all conditions in fighting mine fires.

JOHN H. JONES.

Pittsburg, Penn.

Letter No. 2—In regard to the best method of sealing off a mine fire that has gotten beyond control, I desire to say that, as a general proposition, I would certainly put the first stopping on the intake side of the trouble. My reasons are: (1) This is the coolest and easiest place to work; (2) in most cases it would be quite impossible to put the stopping on the return side first.

After placing the first wall on the intake side, then by properly conducting the air, there should be no serious trouble in building a stopping on the return side.

EDW. H. COXE,

Birmingham, Ala.

Letter No. 3—Referring to your question in COAL AGE concerning fires in a mine, will say that I most heartily agree with the No. 4 superintendent and the No. 7 fireboss. My opinion is that the first stopping should be placed on the return airway. After such a wall has been erected on the return side of the trouble, the men would experience little difficulty in building a tight brattice on the intake, thus shutting off the fire.

W. H. CHURMLEY.

Memphis, Tenn.

Letter No. 4—I have just been reading your editorial foreword concerning mine fires and desire to say I would have proceeded as follows: In the first place, if I had thought there was danger of the flames getting beyond control, I would have sent word through the mine for all the men, except those required for the work of extinguishing the fire, to hurry immediately to the surface.

At the same time, I would have started (working from the intake side) to remove the stopping in the crosscut next outside of the one where the fire was located, if it was possible to get close. If not, I would remove the brattice in one of the crosscuts as near to the fire as I could get, working always on the intake side. I would do this in order to short-circuit the air and thus keep it from feeding the flame.

With the material thus removed, I would build a stopping on the intake entry. My reason for putting the stopping on the intake first is that the men would be working in fresh air.

A stopping can be removed much more quickly than one can be built; it is also a fact that by tearing out the stopping in the crosscut, the air current would be cut off the fire in much less time.

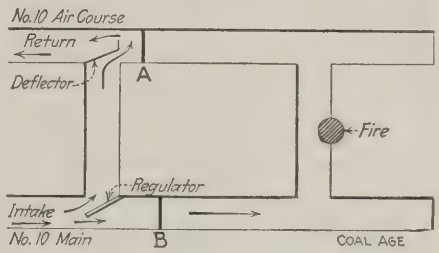
If there were other workings, especially places generating gas on the same split of air, I would endeavor to cut those workings off the split; that is, if they were located on the intake side of the fire.

GEORGE D. EVANS.

Pottsville, Penn.

Letter No. 5—Concerning the question asked in COAL AGE of Jan. 20, 1912, in the last paragraph on page 470, relating to the difference in judgment used by the two sets of officials, resulting in exactly opposite opinions as to the proper plan of attack, I would not consider it possible to prescribe a general method, which would work out with any degree of accuracy for all mine fires. It is true we have rescue helmets for work in all kinds of noxious gasses, but I venture to say not more than 5 per cent. of the bituminous mines have such appliances at the mine. A method of attack where helmets were immediately available, might work out with satisfactory results, while if the same methods were resorted to without helmets, it would certainly result in loss of life to the fire fighters.

If all mines were alike as to thickness of the seam, character of coal, roof and floor, condition as to wetness or dryness, the amount of inflammable gases generated, and the amount of air that could be circulated, then with equal appliances, a general method might be applicable in all cases; however, when conditions vary as widely as they do, it would be unwise to prescribe a hard-and-fast rule for general practice.



SHOWING LOCATION OF FIRE AND POSITION OF STOPPINGS

Fighting a fire without helmets should invariably be commenced from the intake or "fresh air" end, and if in the judgment of the fighters, a stopping should be erected in the air course or return, temporary means must be provided, so the men employed in erecting the stopping can be given fresh air; such an arrangement is shown in the accompanying sketch. It must be understood that in fighting a fire by the direct method, we should invariably do so from the intake end, and the method of procedure in the foregoing case would differ from the plan pursued in sealing off a fire that could not be conquered by the direct method.

In sealing off this fire, or isolating it, the brattice in the return, marked *A*, should be built first, and when completed, the brattice marked *B* should be erected. This would avoid the possibility of an explosion, which would certainly occur if brattice *B* were built first. As soon as the stopping *B* is erected, the supply of fresh air to the fire will be cut off. A large amount of gas will be

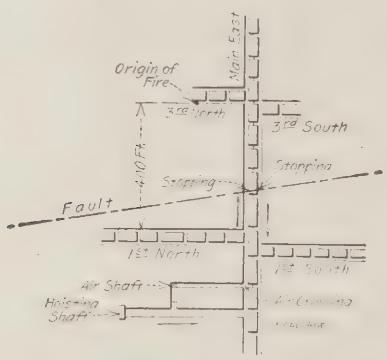
driven off by the heat which will expand the air, and the expanded air and gas will force itself over the fire, and an explosion will occur.

If brattice *A* is built first, an explosion cannot result, because the space between brattice *A* and the fire is filled with the products of combustion, or burnt gases, and this inexplosive mixture fills the space, backs over the fire, and returns to where brattice *B* should be built; also, while this building is going on, perfect safety lamps should be used, so that an explosion cannot occur. In my opinion, the No. 4 superintendent and the No. 7 fireboss were right in their judgment.

Johnstown, Penn. R. Z. VIRGIN.

Letter No. 6—I have had considerable experience with mine fires, but I do not feel that it is a safe plan to lay down any hard-and-fast rule as to how a person should proceed under all conditions. The method I have always adopted where it was necessary to seal off a mine fire, and where two stoppings were required, was to build both stoppings at the same time.

By this method the air current is cut off from the fire completely, there is no unnecessary delay and the danger from any accumulation and consequent explosion of firedamp is reduced to a minimum.



A CASE WHERE THE STOPPINGS WERE BUILT IN A FAULT

The accompanying sketch shows the position of a fire we had to stop off some time ago. The trouble occurred at the face of the third north entry, and extended out to the main east entry. When I was called to the scene, it was utterly impossible to approach the fire, because of the intense heat and large falls of roof.

We decided to seal off the trouble, and the place selected for the stoppings was in the fault shown in the sketch. A temporary wall was built in each entry with brattice lumber and soft clay, both stoppings being erected at the same time; immediately after these temporary brattices were built in, permanent walls of brick and cement were erected just outside the temporary stoppings.

Now, I may state that the north and east entries generated CH_4 and a few days previous to my going to attend to this fire, an explosion occurred at that same point, killing one man and seriously injuring another. These were the only two miners present in that part of the workings at that time.

My method of dealing with other fires has always been along lines similar to the plan outlined above. So far, I have had no occasion to change my ideas, and up to the present no serious accidents have resulted.

Canton, Ill. P. HOGAN.

Letter No. 7—Relative to the proper placing of stoppings when it is found necessary to seal off a mine fire that has gotten beyond control, I would say that, based on personal experience, if the mine is gaseous, stoppings should be erected simultaneously in the intake and return airways, if this be possible. From my personal experience with several mine fires, I do not think it admissible to lay down a positive rule that disregards local conditions. Each fire must be handled with full consideration of all the surrounding circumstances.

ELI T. CONNER.

Philadelphia, Penn.

Letter No. 8—Concerning the treatment of a mine fire that has gotten beyond control, I would suggest that if the fire is located at the face of a pair of entries, the trouble must be attacked from its intake side. I feel sure it would be impossible to approach it in any other way. I therefore agree with the superintendent and foremen at No. 7.

Anglin, Ky. NOAH BURTON.

Letter No. 9—Concerning the discussion of mine fires, and the best way to extinguish them, I want to say that the stopping on the intake airway, in my opinion, should be placed first. In a great measure, if not altogether, this cuts off the supply of oxygen that gives life to the fire.

The second stopping should, of course, be placed on the return side of the fire, and this should be done as quickly as possible to prevent any leakage of gas. If there is any other access to the fire, such points of entrance should be likewise walled off. It is always best to have the stoppings as near to the fire as possible.

Whenever such a plan can be followed, it is well to erect both stoppings at the same time. This latter method is the ideal one for sealing off a bad mine fire.

Republic, Ala. G. T. M.

Letter No. 10—Nothing is more important than quick action and proper treatment in the case of a bad mine fire. Men are endangered and property as well.

My plan of action would be to break down the stopping in the first crosscut, just outside the fire. Then I would build a brattice on the return airway, just beyond the crosscut, in which the brattice had been torn out. Next, I would use a canvas brattice to carry a current of air up the intake and as near to the fire as possible. I would then use fire extinguishers, if such were available. If oxygen helmets were handy, of course we could approach still nearer to the seat of trouble, and the split of air would not have to be carried so far up the intake entry.

If it became necessary to flood the fire, I would build a stout wall on the return side, and let a pipe project through the stopping so that the steam might escape. A wall would also have to be built on the intake side and both these stoppings should be of brick or concrete.

I certainly agree with the No. 4 superintendent and the No. 7 fireboss. To explain why, let me cite a simple case: Suppose we have a fire in the kitchen stove; then assume a man is at the end of the pipe or top of the chimney; if you shut the draft off, your pipe still feeds smoke. It is, therefore, necessary to close the pipe as well as the doors, and the fire will die out; the man at the end of the pipe would be safe. If only the draft were cut off, or the fresh air shut off first, the pipe would smoke and the man would perish.

Red Ash, Va. A. T. WADE.

Letter No. 11—As to whether I would place my first stopping on the intake or on the return side should I desire to seal off a mine fire, will say that my plan of action would depend entirely on physical conditions and circumstances in connection therewith. I have known it to be done in both ways with more or less success.

The general practice seems to be to close the outlet first, having in mind the construction by brattice or otherwise of a separate return on the intake to a point as near the fire as possible. My practice in combating mine fires is to use the direct method and with prompt action and proper appliances I have never seen a failure.

GENERAL MANAGER.

Scranton, Penn.

Letter No. 12—I think the No. 4 superintendent and the No. 7 fireboss were right in wanting to place the first stopping on the return side of the fire. This plan prevents the smoke and fumes from traveling to other parts of the mine. If you build the first stopping on the intake side of a fire, and you have no helmets available, it is then impossible to build a wall on the return airway, because of the smoke and fumes that you encounter.

If I should meet with a fire similar to the one described in COAL AGE last week, I would build both of the stoppings at the same time, erecting the brattices by building from the bottom up.

Bosworth, Ky. DAVID WATKINS.

Letter No. 13—I would advise placing the first brattice on the intake. The su-

perintendent and foreman at No. 7 mine were right.

GEORGE S. BARROWMAN.

Eldorado, Ill.

Letter No. 14—In discussing the best method of dealing with a mine fire, I desire to say that if local conditions are eliminated, there arises room for considerable discussion. It has been my experience to contend with but two fires and my training in this line, therefore, has been necessarily limited. In one of the fires referred to, we had no time to build stoppings and there was only enough time for us to effect a safe escape. The second fire was extinguished with water.

However, should I encounter a fire, such as was described in COAL AGE, and if I had no one with me whose experience in dealing with the problem was greater than my own, I would construct the stoppings on the intake and on the return simultaneously. My plan would be to do the work in the following way:

First, I would select a crosscut as near to the fire as possible and I would then have the men open this crosscut, short-circuiting the air, and in this way, partially cutting off a supply of oxygen from the fire. This, I believe, would also give the workmen ventilation in the intake and return. If conditions were such as to prevent building both stoppings simultaneously, I would attempt to construct the first stopping on the intake, short-circuiting the air at a point near the location of the stopping. I believe, however, that local conditions would have to govern the method of procedure.

G. M. SHOEMAKER.

Pennington Gap, Va.

Letter No. 15—In all our experiences in sealing off mine fires, we have closed the intake side of the fire first.

DOUGLAS BUNTING.

Wilkes-Barre, Penn.

Letter No. 16—As to the best method of sealing off a mine fire that has gotten beyond control, assuming, of course, as specified, that all local conditions be disregarded, the answer to this question, in my opinion, would be to build the first stopping on the intake side of the fire, as the stoppage of the air current passing over the fire would reduce the amount of the products of combustion in the return and give a better opportunity for the building of the second stopping. This procedure would be reversed in the case of workings giving off a large amount of explosive gas, in which case the return stopping should be built first to minimize the danger of accumulations of gas and explosions at the seat of the fire; in this case the intake air current should be utilized to dilute the gases given off and the stopping built in the return, despite the difficulties which would be encountered from the vitiated air from the fire.

In modern colliery practice, with reversible fans, or where the ventilation is so planned that the air current may be reversed at the location of the fire, the first stopping would properly be built on the intake side, the current then reversed and the second stopping built in good air.

In every case, in practice, local conditions will necessarily govern, and the location of stoppings cannot follow any general rule, but must be determined on the ground; the extent of the fire, character of workings, amount of water supply, presence or absence of gas in quantity, amount of timber affected by the fire, proximity of other danger points and facilities at hand for fire fighting, such as chemical extinguishers, oxygen helmets and the like, will necessarily have a preponderating influence in the decision of the question.

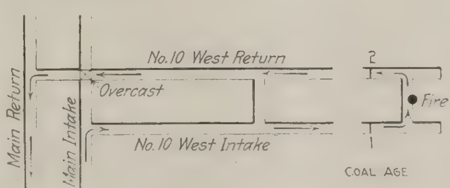
R. V. NORRIS.

Wilkes-Barre, Penn.

Letter No. 17—In discussion of the article on mine fires on the first page of COAL AGE, Jan. 20, I wish to state that I do not believe it possible to prescribe in general whether a fire at the face of a pair of entries should be sealed off, first on the intake, or first on the return side, because local conditions and facilities cannot be disregarded. The only general rule to be followed in sealing off a mine fire is to cut off the supply of air as quickly as possible, with due regard to safety.

To take the case cited (see accompanying sketch), we are confronted with the following conditions:

1. We are in a mine which generates gas, but is not considered dangerous, and therefore is the most dangerous kind of a gaseous mine.
2. The mine is ventilated by the pressure system.
3. The fire is at the point indicated on the sketch.



SHOWING PLAN WHERE FIRST STOPPING IS PLACED IN RETURN

It is assumed that rescue helmets are available to enable work being carried on in smoke, etc. With the above conditions before me, I would place the first stopping at the point 2 in the return airway.

The fire has been burning for some time without causing an explosion, with the conditions of ventilation and pressure as found. If we alter these conditions by building the first stopping at a point 1, in the intake airway, we will increase the chance, and in fact make conditions most favorable for the escape of any gases that may be present, with the consequent risk of an explosion.

On the other hand, by placing the first stopping at 2 in the return, we not only do not reduce the pressure until the last moment, when it is safe to do so, but also as quickly as the barrier is built in the return, the smoke and gases of combustion are driven back over the fire and aid in smothering the same. On completing the barrier at 2, the stopping at 1 can be built in comparative safety and the fire completely sealed off.

It is quite possible that conditions might make the placing of the first stopping at 1 instead of at 2 the best plan; but those local conditions must be known before the situation can be intelligently handled.

In conclusion I would suggest that many cases of uncertainty and hesitation (which may prove disastrous) in handling a crisis of this nature in a mine, may be avoided if managers, or superintendents, would get the foremen, firebosses, etc., together at least once a week, and with the mine plans before them, discuss thoroughly the best and safest method of procedure, in case of fire, "cave in," or any other possible accident or disaster that might occur.

I have used the plan outlined above with successful and gratifying results.

JOHN T. FULLER.

Honesdale, Penn.

[*Our space being too limited this week, letters from James Ashworth, John Verner and others will be published in our next issue.*—EDITOR.]

Truesdale No. 1 Coal Shaft

The two shafts at the Truesdale colliery of the Lackawanna company, near Nanticoke, Penn., although at present called upon to handle only a small amount of coal, were designed and equipped for taking care of a large output in the future. Steel headframes, self-dumping cages and the permanent hoisting-engine equipment were installed. On the front cover of this issue is given an interior view of the hoisting-engine house at No. 1 shaft, which extends to the Ross vein at a depth of 590 ft., and cuts the Baltimore vein on the way down. A landing will probably be established in the latter seam at some future time.

The hoisting engines for this shaft are provided with a tight and a loose drum for hoisting from several levels, and will wind 900 ft. of $1\frac{1}{2}$-in. rope, so it will be seen that considerable allowance was made for possible future developments. These engines were built for the Lackawanna company by the Vulcan Iron Works, Wilkes-Barre, Penn., and are 30x48 in., double-drum, direct-acting or "first-motion" engines of modern design with steam and hand brake and steam reverse. The drums are semi-conical and taper from 9 to 11 ft. The loose drum is controlled by a steam-operated clutch, which is, of course, not used at present in hoisting from only one level.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Alabama Mine Foremen's Examination Held at Birmingham, Ala., Jan. 22-27, 1912

First-Class Mine Foremen Questions

Instructions To Miners

Ques.—What instructions would you give to miners relative to their duties when hiring them; also what instructions would you give them when making your daily rounds?

Ans.—I would first test their ability to read and understand the printed and written notices that it is the custom to post in and about the mine, and instruct them to read and obey them absolutely.. If the mine generates gas, I would give each man careful instructions in regard to the danger of gas; the different kinds of mine gases; the use of safety lamps. If electricity is used in the mine, I would explain to him its danger and the need of constant care to avoid contact with a live wire or any charged iron pipe or tool.

When making my daily rounds I would observe his method of mining the coal, placing shots, caring for powder, charging and firing holes, setting posts and testing the roof. I would observe his safety lamp and give him further instructions, if necessary, in regard to its proper use.

Instructions To Firebosses

Ques.—If you were acting as mine foreman at a gaseous mine what instructions would you give to your firebosses relative to the performance of their duties?

Ans.—I would instruct them to do their work conscientiously and to faithfully examine every working place, in their respective districts, for gas and other dangerous conditions; and to mark the date at the face of each place examined, and place danger signals at the entrances to all places where gas or other danger is found. I would require them to enter, in a book kept for that purpose, a full report of each examination made of the districts in their several charge, and to sign such report. I would further instruct each fireboss to make a verbal report to me, after each examination and advise me personally of any dangers requiring prompt attention.

First Duties of Mine Foreman

Ques.—On entering upon your duties as foreman of a mine that has been in operation for some time, what would you consider your duty in order to make a reputation for yourself and do justice to your employer? What stand would you take with the men, and what would be your first duty upon taking charge and what would be the first thing you would call for?

Ans.—The mine foreman must make a calm, deliberate, but firm stand for what is right between man and employer. Much will depend on his judgment and tact in minimizing the numerous and, for the most part, trivial causes of friction that are bound to arise, from time to time, between the men and the company. The mine foreman's first duty is to prove by his actions and words that his desire is to treat fairly and honorably with both his employers and the men in his charge.

He should demand "a day's work for a day's pay" and treat all men alike on this basis, having no favorites. He should get next to his men in such a way that they will feel both the influence of his sympathy and the force of his will. After acquainting himself thoroughly with the mine and the men, he should call for an accurate mine map and study the same carefully, in every detail, to enable him to decide what, if any, improvements can be made in respect to ventilation, drainage, or haulage.

Ventilation of the Working Face

Ques.—What method would you adopt to have a continuous flow of air past the face of each working place?

Ans.—The air current must be properly directed so as to sweep the face in all working places. In longwall work this is a comparatively easy matter, because where the roads leading to the face are properly curtained with canvas the air follows naturally the line of the working face. In room-and-pillar work, however, it is more difficult to keep a steady flow of air continuously sweeping the faces of the several rooms and headings. As the rooms advance the face gets farther and farther from the last breakthrough by which the air enters the place; and, as a consequence, less air reaches the face, unless a temporary brattice of canvas is used or the waste is built up in the room in such a way as to conduct the air forward to the face.

In room work the breakthroughs or cross-cuts in the pillars between the rooms should be "staggered"; that is to say, they should not be driven opposite to each other; so that one breakthrough will always be not more than half their distance apart, from the face of the room. When this method is adopted it is easier to keep the air up to the face.

In order to insure a continuous air current in the mine workings, it is necessary, also, to build and maintain good airtight stoppings, brattices, doors and airbridges. Double doors should be used at all points between the main air course and return, so as to prevent the temporary short-circuiting of the air when one of these main doors is open to allow the passage of a man or mule.

Control of Two or More Air Splits

Ques.—If you had two air splits in a mine, would it be possible for one of them to work to the disadvantage of the other; and if so, how would you prevent it?

Ans.—Yes; assuming the splits have like cross-sections, the short one will take the most air; or, in other words, the shorter split will rob the longer one of a portion of its air. This is prevented by what is called a "regulator," which is a brattice or wooden stopping built in the airway that takes naturally more than its desired portion of air. The brattice is arranged with a central orifice or opening provided with a sliding shutter, to increase or decrease the size of the opening. By moving this shutter it is possible to obtain any desired division of the air current between the two splits.

Again, when one split runs to the rise and the other to the dip, there will generally be a variation in the circulation in the two splits, according to the season. For example, in winter, the intake air will be colder and therefore heavier than the warm return air. As a consequence, there will be formed, in the dip split, a natural air column assisting the established circulation in that split. Also, in the rise split, will be formed a natural air column opposing the established circulation in the rise split. In the summer, when the intake air is warmer than the return, the natural air columns formed will oppose the circulation of air in the dip split and assist that in the rise. Therefore, in this case, the dip split will rob the rise in the winter; and in summer the rise split will rob the dip. This will require an alteration of the regulator according to the requirements and the season.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Bunker Coal at the Panama Canal

Discussions before the House Committee on Interstate and Foreign Commerce during the past week have been made to turn in an increasing degree around the question of coal supplies for ships passing through the Panama Canal. The committee has been furnished with elaborate data as to vessel tonnage, the amount of space on board required for bunker coal, the amounts needed to be kept in store at the isthmus, in order to enable vessels to coal there, and a variety of other matters. From the navy standpoint, Secretary Meyer has urged the building of a fleet of 12 or 15 colliers, to furnish the coal supply on the isthmus that would be needed by American war vessels passing through the canal.

There seems to be a decided growth in the view that the problem of coal will play a most important part in connection with the question of toll rates. One of the plans which has been urged upon the committee is that of taxing vessels in proportion to their displaced tonnage, thereby imposing the taxation most heavily upon those that are already furnished with freight. This, however, would discriminate against various classes of the freight carried, and would presumably increase the burden upon those ships which attempted to pass through the canal with a full coal supply, instead of arriving light, and coaling after they had passed through the canal and had paid their tolls. Of course, if the tolls were simply a flat sum, paid at the same rate whether a vessel were loaded or not, this consideration would not figure, but it is already evident that the question of cheap and available fuel supply is to play a large part in determining the character of the freight that will go through the canal, and the rate of charge that must be made for it.

Leasing System for Public Lands

Conservation of public lands by means of the leasing system was discussed at length by the Senate committee on public lands, on Jan. 24, and it is more than probable that at the next meeting of the committee, the Newlands resolution, in favor of action by Congress at this session, will be adopted. The discussion of the 24th was a continuance of the one begun a week earlier, when it was proposed that instead of waiting to perfect a bill, the committee shoud give evidence of its intention to act by declaring in favor of the leasing system and then perfecting the details of a bill later.

Senator Newlands maintained that it was high time that action should be taken to protect our natural resources in coal, iron, etc., against monopolistic control under a system of leasing. It appeared that a substantial majority of the committee favored the leasing plan, provided that the revenues, apart from the expenses of administration, would be turned over to the states in which the resources were located.

It was urged that the Western states would not consent to any system that would make them provinces of revenue for the national government; that to withdraw these extensive and valuable tracts from the taxing power of the states would be to cripple them most effectively and to deprive them of the advantages which sister states had enjoyed by the transfer of title to individuals and the consequent taxation of the land. The committee was practically unanimous in the view that the control of the United States should be maintained, not for revenue, but simply to prevent monopoly; that the leasing system should not be pursued for profit, and that the proceeds of the leases should be turned over to the respective states.

It was suggested that the division be made on a basis of 25 per cent. to the general government and 75 per cent. to the states, and it is hoped a resolution will be presented at the next meeting that will insure harmony of action. For many years various conservation measures have been before this committee without substantial result, a fact urged by Newlands in advocating a declaration of policy, after which the perfection of a bill will be a comparatively easy matter.

Alabama

Birmingham—The Pratt Consolidated Coal Co. announces that two colliers will be built and equipped at a cost of $100,000, in preparation for the exportation of Alabama coal from Mobile and Pensacola.

The regular semi-annual examinations for mine foremen and fire bosses were held here Jan. 22 to 27, inclusive. Sixty-four entries were recorded on the first day.

It is reported that the Nashville, Chattanooga & St. Louis R.R. has renewed a contract for 125,000 tons of coal from the Whitwell mines of the Tennessee Coal, Iron & R.R. Co.

California

Salinas—The company operating the Stone Cañon coal mines in the southern part of Monterey County is soon to renew efforts to extinguish a fire which has been smouldering in one of the inclines for the last two years. It is proposed to sink a shaft some distance beyond the fire and to wall up the burning area. That part of the mine where the fire exists will then be flooded. At present no one can enter the incline owing to the presence of gases generated by the smouldering coal.

San Jose—A. B. Campbell recently filed suit in the Superior Court here against each individual stockholder of the Monterey Coal Co., the defendants numbering more than 100, in which he demands $331,231, alleged to be due as commissions on the sale of stock.

Colorado

Denver—Operation of coal mines by the consumer is the policy of the Consumers' League, of Denver, which has incorporated under the title of the Consumers' Fuel & Merchandise Co., for the purpose of running mines and delivering the output to its members. The plan is to sell five $10 shares to each consumer, entitling him to purchase coal and to share in any profit that may accrue.

The Colorado - Wyoming Coal Co., which has a capital of $6,000,000, recently elected officers. It reports holding 1200 acres of lignite coal and expects to produce a large tonnage when necessary improvements have been made. It is said that one mine at Tracyville will be able to ship 300 tons a day within a month. This company is affiliated with the Denver, Laramie & Northwestern R.R., which has recently approved plans for a 152-mile extension from Greeley to Elk Mountain.

Grand Junction—The city commissioners have instructed Director Shaffer, of the bureau of municipal activity, to find, if possible, a market for the millions of tons of undeveloped coal in Mesa County. It is intended to sell the coal on the Pacific slope, if possible, and Director Shaffer has been ordered to begin an advertising campaign with that end in view, and to make an effort to secure favorable freight rates.

Illinois

Duquoin—It is understood that 8000 acres of Franklin County coal land have been purchased by C. W. Seilley of Benton, representing ex-Mayor Busse of Chicago, and W. P. McMillan, also of Chicago. It is also said that a shaft will be started at once to open up this tract.

Marion—The roof of the Chicago Big Muddy Coal & Coke Co.'s mine gave way recently at a point under the water reservoir, and several narrow escapes from drowning were reported.

Belleville—The Missouri & Illinois Coal Co. has enlarged its mines at Rentchler Station, east of Belleville, and at Willisville, southeast of Belleville, and is installing an electric power plant at the St. Clair mine, near Freeburg, to furnish power for the St. Clair and Wilderman mines. A complete new equipment has been installed in the Star mine at Freeburg, including electric puncher mining machines, while a large new engine and electric mining machines are being placed in the Mulberry Hill mine.

The Illinois mine-rescue car arrived in Belleville, Jan. 21, for a stay of several weeks.

Indiana

Clinton—Five hundred miners at the Brazil Block mine No. 8 were recently imprisoned for the greater part of a day, when the hoisting rope of one of the cages parted and let the cage, loaded with coal, drop to the bottom of a 200-ft. shaft. It required about four hours to lift all the men out on the other cage remaining in service.

Booneville—An important business transaction was consummated Jan. 22, when Wilson Bros. sold their interest in the Wilson-White Coal Co. to the Erie Canal Coal Co. It is the intention of the new company to make extensive improvements to the property in order to increase the mine's output to at least 1000 tons per day.

Jeffersonville—An ice gorge here, Jan. 20, caused an estimated loss of $30,000, including boats and barges of coal, coal floats and other property. The gorge broke at 2 o'clock in the morning and in 20 minutes the destruction was complete.

Kentucky

Rockport—Refusal to enter the mines of the Rockport Coal Co. here when requested resulted in a wholesale discharge of the miners, and now nearly 100 men are idle as the result of the ultimatum issued by President Tucker, who declares the men shall not return to work while he is in charge.

Pineville—The commissary of the New Bell Jellico Coal Co. at Bell Jellico was recently destroyed by fire. The loss amounted to about $8000, and is said to have been covered by insurance.

Louisville—The stockholders of the Continental Coal Corporation have organized a selling company with a capital stock of $500,000, to handle the output of the corporation, which operates in the eastern Kentucky coal field. The new company has the same officers as the operating company and will have headquarters in Chattanooga. The Continental Coal Corporation was formed recently by the consolidation of various mines in Bell County.

The Consolidation Coal Co., operating in the Elkhorn field, reports eight mines opened and entries driven, and seven tipples in process of erection, while machine shops, stables and other necessary buildings are rapidly being built. Six more mines have been located and are in process of development. Two hundred miners' houses have been completed and 800 more are in process of erection. A central power plant has been started and temporary power plants are already in operation. All this and other work has reached such a state of development that upon the completion of the first transportation line, the Sandy Valley & Elkhorn R.R., Apr. 1, the present mines will be able to start with a production of at least 2500 tons a day, which will be increased rapidly.

Adjudging that the McNary Coal Co. has failed to carry out the provisions of its 20-year lease of 2100 acres of coal lands, belonging to the Krauth & Fable estate, in Muhlenberg County, Judge James Quarles has signed a judgment declaring the lease forfeited and annulling the contracts.

Nevada

Tonopah—A. S. Thomas, an experienced coal miner, recently made an examination of the Coaldale coal mines and returned to Tonopah with the assurance that in a short time coal from the new fields will be shipped into the southern country. The Nevada Coal & Fuel Co., under the supervision of T. E. Rovinack, has a force of men developing the large veins of coal on its property. The 8-ft. vein on the 75-ft. level is being drifted both north and south and continues its average thickness as the drifts advance. At the T. A. Darms property a shaft has been sunk to a depth of 320 ft. The shaft has a dip to the 280-ft. level of 95 deg., and from that point to the bottom the dip is 20 deg. This property covers an area of 960 acres and has been under development for the past two years, the principal owners being California capitalists.

Ohio

Byesville—Defective electric wiring was responsible for a recent fire which caused a loss of several thousand dollars and endangered the lives of 200 men employed at the Little Cape mine of the National Coal Co. at Byesville. The men escaped through an emergency shaft. The day crew of miners had entered the 100-ft. shaft and were at work when the fire was discovered. Exit by means of the main shaft was cut off and the emergency shaft probably saved many lives. Timbers in the mine were burned and tons of slate had fallen before the fire was checked.

Gallipolis—With the resumption of navigation on the Ohio River more than 1,000,000 bushels of Kanawha and Pittsburg coal, bound for Cincinnati and Louisville, were liberated from the ice. This precludes the possibility of a coal famine in those two cities.

Wellston—The Lake Erie & Ohio River Ry. & Transportation Co., and the International Mining & Manufacturing Co., which have for their purpose the development of coal lands in Jackson, Vinton and Scioto counties were organized recently. The railroad company has a capital of $8,000,000 and will have for its president and general manager, B. F. Howland, of New York. E. B. Bingham is president of the manufacturing company which is capitalized at $25,000,000.

Columbus—At a meeting of the Hocking Valley Operators Association, E. A. Cole and G. C. Weitzel, official heads, respectively, of the Sunday Creek company and the New Pittsburg Coal Co., were selected to represent that body at the joint-wage conference in Indianapolis. As these two corporations are the largest in the Hocking Valley and as this field dominates the state in such matters, it is safe to say that Ohio is committed to a revival of the interstate movement. Ohio coal interests insist that their representatives shall not recede in any way from opposition to a mine-run scale, such as prevails in Illinois, and if this obstacle cannot be overcome in the process of negotiations, Ohio, western Pennsylvania, and Indiana will tie up together.

Oregon

Beaver Hill—An explosion at the Beaver Hill mine, in the Coos Bay district, recently caused serious injuries to four employees. The explosion is reported to have been caused by an electric spark igniting the gas.

Klamath Falls.—Extensive operations are expected soon at the Cascade coal mines property north of Ashland. The property was recently optioned to Seattle capitalists for $300,000—the option to be good for ten years. A royalty of $4,000 is to be paid the first year and $8,000 per year thereafter. The first work to be undertaken is the sinking of a 1000-foot inclined shaft. For this and other work about the mine there will be installed a

complete new outfit of modern machinery. There are five and a half feet of coal now showing in the principal vein and it is expected this will increase to 12 or 15 feet.

Pennsylvania

Bituminous

McKeesport—Five hundred men were put to work Jan. 26, at the mine of the Monongahela River Consolidated Coal & Coke Co. at Bunola, near McKeesport. The mine has been shut down since last September.

Connellsville—The Dunlap-Connellsville Coke Co. awarded a contract Jan. 23 for the erection of 10 houses at the Garwood coke plant, near Brownsville, to cost $10,000. The company is preparing to fire to capacity its plant of 119 ovens, 57 of which are now in blast. Scarcity of labor is handicapping operations.

Within the past three weeks over 4000 idle ovens have been ordered into blast, but they have been unable to get to their productive capacity because of the necessary delay in supplying on so short a notice the complement of men. This complement is a small industrial army of between four and five thousand. The extreme cold weather has also been a serious handicap.

Johnstown—The Valley Smokeless Coal Co. has secured from the Von Lunen estate the right of way over property skirting the Stonycreek River, for a branch railroad to connect with the Pennsylvania R.R., via the Johnstown & Stonycreek Ry. Work on the construction of the spur is to begin at as early a date as the weather will permit, and the coming spring will give the company another outlet for the transportation of its coal to market.

John F. Summerville has started the opening of new mines on the Snyder and Zimmerman tracts in Black township. These mines will furnish locomotive fuel for the Western Maryland Railroad.

Pittsburg—Following a recent meeting of the directors of the Monongahela River Consolidated Coal & Coke Co. it was stated that no steps had been taken to place the company under the operating management of the Pittsburg Coal Co., and that it is probable that the company will be operated as an independent corporation for some little time. The president's report shows that the company now owns 17,950 acres of coal lands in Pennsylvania and 2456 in Kentucky. It mined 7,632,054 tons of coal during the fiscal year under review, which ended Oct. 31, 1911, compared with 7,755,144 tons in the previous year, a decrease of 123,090 tons, out of which smaller tonnage, however, the company derived greater earnings than in the previous year.

Anthracite

Scranton—The anthracite mine workers' joint wage-scale committee will meet with the hard-coal operators at the office of the Central Railroad of New Jersey, in New York, Feb. 27.

Wilkes-Barre—The coroner's jury investigating the explosion in the Parrish mine of the Parrish Coal Co. on Jan. 9, in which six men lost their lives, returned a verdict holding the company responsible for failure to take the proper precautions to protect the lives of the victims.

The State's new anthracite law code commission, named by Governor Tener a short time ago, began work at Wilkes-Barre, Jan. 20, Senator Catlin, the chairman of the commission, presiding.

Pittston—Work has progressed so far that it is expected the plan of the Erie company to get coal from the abandoned workings of the old Schooley shaft in Exeter borough will become operative about the first of April. The Schooley mine has been idle for a number of years, having been flooded by a serious mine squeeze.

Three dwellings in the borough of Yatesville, near here, were disturbed by a mine cave, Jan. 23. The cave is thought to be due to a settling of the workings in the Yost colliery.

Mt. Carmel—Three mine workers were killed in the Alaska shaft of the Philadelphia and Reading Coal and Iron Co. while at work in the night of Jan. 24. The men were caught in a cave-in and their bodies were found after fifty tons of rock and dirt had been removed.

Shamokin—Between six and seven hundred men and boys, employees of the Enterprise colliery, operated by W. L. Connell & Co., of Scranton, went on strike Jan. 22. They claim that the price charged them for timber is excessive.

Utah

Ogden—The defunct Elk Coal Co. has quickened into life in a new corporation at Ogden, which recently filed articles of incorporation under the name of the Mammoth Coal Mining Co. The capital stock is $500,000, in $1 shares, fully paid up by a note for $125,000 signed by the organizers of the new corporation and given to secure the amount paid by J. W. F. Volker at assignee's sale for the property of the Elk Coal Company.

Salt Lake City—The Orem and Berryhill interests in the Castle Valley Coal & R.R. Co. in southern Utah have passed to James H. May for a consideration of $450,000. Mr. May and his associates now have absolute control of the company, which is capitalized at $5,000,000. The new control has arranged for a $1,000,000 bond issue with which to make extensive improvements. The present daily capacity of the mine, 1200 tons, is to be increased to 3000 tons and steps are to be taken to free the company from dependence on the Denver & Rio Grande R.R. Co. for transportation facilities by the purchase of several hundred coal cars for its own exclusive use.

Washington

Spokane—The Tanum Coal Co. has been organized at Spokane with an authorized capital stock of $500,000 to develop a tract of coal land on Tanum Creek, near Ellensburg, Wash., in the Roslyn district. Analyses of the coal, made by A. N. Cantrill, manager of the Spokane Gas Co., show it to be one of the best grades of gas and coking coals that has yet come to his attention.

West Virginia

Keyser—The suit for $10,000 damages against the Davis Coal & Coke Co. by the administrator of William Hetzel, who was killed with 22 others in an explosion of mine No. 20 at Elk Garden, Apr. 24 last, was brought to an abrupt close when Judge Reynolds sustained a demurrer to the evidence. The case will be carried to the Supreme Court. Like cases by the administrators of Harry Trenaum and John White, two other victims of the ill-fated mine, will come up later.

Berkeley Springs—The land deed of the Sleepy Mountain Coal Co., through Special Master John C. Berry to Hay Walker, has been recorded here. The land involved lies in Morgan and Berkeley Counties and includes about 15,000 acres. The consideration was $250,000.

Parkersburg—In the opinion of the Board of Army Engineers, it is not considered practicable for the government to undertake at this time the improvement of the Little Kanawha River, which flows into the Ohio at Parkersburg. There are five locks and dams at present, affording a four-foot stage from Parkersburg to Creston, 48 miles above. Coal interests wanted improvements that would insure a six-foot stage to Burnsville, 74 miles above Creston. The engineers, after making a preliminary survey and an exhaustive study of the river, report that the proposed improvements would cost not less than $5,000,000 with $54,000 annually for maintenance.

Charleston—The New River Mining Institute, organized for the purpose of instructing its members in the mining industry, has a membership of about 70, and recently met at Scarbro for the election of officers. The institute is composed of men employed in various capacities about the mines. Similar organizations will be started in every mining section of the state.

Personals

A. D. Locke, of the Bonnie-Brae Coal & Quarries, Ltd., of Calgary, Alta., recently made a business trip to New York.

F. R. Wadleigh, fuel engineer and assistant general manager of the Chesapeake & Ohio Coal & Coke Co., has recently made an extended trip through Michigan, returning East this week.

C. H. Ashen has been appointed manager of the Buffalo agency of the Pittsburg-Buffalo Coal Co. Mr. Ashen, as a coal salesman, has helped materially to build up the business for several years past. He succeeds T. J. McNamara, who has held the position some time.

James W. Barber, secretary and treasurer of the Monongahela River Consolidated Coal & Coke Co., will take charge of the docks and mills of the company at Elizabeth on Feb. 1, according to an announcement made Jan. 22. He will be succeeded by C. H. Van Dyke as secretary and treasurer.

J. F. Hannigan has resigned as superintendent of the Edgewater mine of the Tennessee Coal, Iron & R.R. Co. and will be succeeded by George W. Brymer, of Philadelphia, Penn. Mr. Brymer was, some time since, a transitman with the Lehigh Valley Coal Co., at Wilkes-Barre, Penn., and has recently been engaged with Mr. E. T. Connor at Philadelphia.

Benjamin F. Bush, president of the Denver & Rio Grande R.R. Co., recently made a thorough inspection of the Sunnyside mines operated by the Utah Fuel Co., a subsidiary organization of the Denver & Rio Grande. It is understood that it will be the policy of President Bush to encourage the independent coal companies in southern Utah by affording them better transportation facilities to their markets.

Edwin Ludlow has been appointed second vice-president and general manager of the Lehigh Coal & Navigation Co., with residence and office at Lansford, Penn. The office of general superintendent, made vacant by the resignation of Baird Snyder, Jr., has been abolished. Mr. Ludlow is a graduate of the School of Mines of Columbia College. From 1882 to 1889 he was superintendent of the Mineral Ry. & Mining Co., Shamokin, Penn., in charge of the anthracite-mining operations of the Pennsylvania R.R. Co. in that field. From 1889 to 1899 he was superintendent of mines of the Choctaw, Oklahoma & Gulf Ry., Hartshorne, Indian Territory. From 1899 to Jan. 1, 1911, he was general manager of the Mexican Coal & Coke Co., Las Esperanzas, Mexico, and from Jan. 1, 1911, to Mar. 1, 1912, vice-president and general manager of the New River Collieries Co., Eccles, W. Va. Mr. Ludlow brings to his new situation a long experience with mining problems and mine management.

Obituary

Phineas Stewart Berry, 64 years old, died recently at his home in Brooklyn, N. Y. Mr. Berry was with the Coxe Brothers Coal Co. for many years.

Adam Keil, aged 60, for many years identified with coal mining in the vicinity of Pittsburg, died recently at his home on the north side. He was born at Stonesburg, Penn., and was for a time employed as a pilot on steamboats of the local rivers. He later became interested in coal operations and was, at various times, associated with Louis Staib, the W. H. Brown Coal Co., James Jones & Sons, the Monongahela River Consolidated Coal & Coke Co., and the Pittsburg-Buffalo Co. Mr. Keil was a prominent member of the Mining Institute of America, and had always been active in mining and river affairs.

Alexander Lear Stoek, 13 years old, only son of Prof. and Mrs. H. H. Stoek, of the mining engineering department of the University of Illinois, died, Tuesday, Jan. 16, at his home in Urbana. He was in the freshman class of the Thornburn high school, Urbana, where he was greatly esteemed. About five weeks ago he was taken with a severe headache and as it did not yield to treatment, he was later taken to St. Luke's hospital, at Chicago, and was there examined by a number of specialists, who after exhaustive tests diagnosed the trouble as either a tumor or a tubercular growth at the base of the brain, where it could not be reached by an operation or by medicines.

Construction News

Charleston, S. C.—The Carolina, Clinchfield & Ohio R.R. Co. will build large coal docks at Charleston in anticipation of export trade following the opening of the Panama Canal. The docks will cost $600,000 and will be financed through the Clinchfield Coal Co.

Boston, Mass.—The Island Creek Coal Co. proposes to build a dock at the head of the Lakes, which will be one of the most modern coal-handling plants at the Twin Ports.

Belleville, Ill.—The Missouri & Illinois Coal Co. will build and equip a new tipple at the St. Clair mine, near Freeburg, Ill. A new power plant and electric haulage system are now being installed.

Salt Lake City, Utah—The United States Coal Co. is about to open a coal mine upon its land three miles west of Kemmerer, Wyo. Bids are wanted for driving two slopes 1000 ft. in the coal. C. V. Gould is engineer.

Kansas City, Mo.—The Lowe Pilgrim Mining Co., with $25,000 capital stock, has been incorporated by E. C. Gussman, W. C. Dillon and E. J. Dillon to equip and operate mining property owned by the incorporators.

New Publications

FATAL ACCIDENTS IN AND ABOUT THE MINES AND QUARRIES OF THE UNITED KINGDOM DURING THE YEAR 1911. Darling & Sons, Ltd., 34 to 40 Bacon St., London, E. 9 pages.

The report on British accidents is already on hand. Allowing seven days for it to reach our hands the report must have been published before Jan. 19. This unequaled rapidity might well be commended to the dilatory inspectorates of the various states and Nation. The report is not dated and appears without the customary letter of transmission to the Secretary of the Home Department, so anxious is the chief inspector to get his report into print in suitable time. The more detailed report will follow later, but even this advance proof contains six full-page tables.

The number of fatal accidents in such British mines as are covered by the Coal Mines Regulation Act decreased considerably in 1911, as was foreshadowed in our issue of Jan. 13, in an article entitled "Larger Coal Mining Catastrophes." Both the number of separate accidents and the deaths resulting therefrom were reduced, the former from 1242 to 1206 (2.9 per cent.) and the later from 1775 to 1259 (29.1 per cent.) The reduction in the number of accidents was so slight as to suggest that at any time, years as high in death rate as was 1910, may well recur. An explosion or mine fire is accompanied by a large or small death rate, according to the number, great or small, exposed to its violence or poisonous influence.

The report shows a reduction in deaths from explosions of gas and coal dust of 92.7 per cent. Accidents from roof falls have decreased slightly, but not enough to show the value of systematic timbering. It will be remembered that recently in British mines local regulations ("by-laws") were made requiring certain definite spacing and methods for timbering, and it was hoped that by the introduction of these new measures a great falling off in the death rate from falls of roof would be apparent. Shaft accidents appear to have increased, but miscellaneous accidents underground have materially decreased, and a slight improvement is to be noted in the number of surface accidents.

Trade Publications

Stromberg-Carlson Telephone Manufacturing Co., Rochester, N. Y. Bulletin No. 1003. Telephone supplies and telephone construction material. Illustrated, 206 pages, 7½x10 inches.

Ridgway Dynamo & Engine Co., Ridgway, Penn. Bulletin No. 22. Four Valve Engines. 22 pp., 8½x10 in., illustrated. Bulletin No. 24, Alternating-Current Generators. 12 pp., 8x10½ in., illustrated.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

Contrary to expectations the return of mild weather does not appear to be developing any surplus coal. The large tonnages which accumulated on sidetracks during the cold snap have been moved in, and together with the present heavy production, are being readily absorbed, with hardly any perceptible slackening in the demand. This would seem to indicate that the supplies were more seriously depleted than was thought, and it is generally conceded that the trade now is more active than at the same period in any previous year.

The coastwise markets in the East continue strong and active especially in anthracite, the production of which, it is thought, is not equal to the consumption. No spot anthracite is to be had, and the market will probably continue tight up to Apr. 1. Bituminous is somewhat slower but in good demand.

In the Pittsburg district the mines are working well up to capacity and prices continue hard and steady with even a slight increase in slack; railroad deliveries here are still slow. The Ohio field reports January one of the best months in the history of its coal industry. Some steam plants have been compelled to close down through lack of fuel and while transportation is still crippled to a certain extent, the mines are working well and heavy tonnages are being moved.

The market in the Middle West is softer, but prices are ruling fairly strong. Transportation troubles are still in evidence and another cold spell would probably make the situation acute, as the equipment on the railroads appears entirely inadequate. Some manufacturing plants are reported to be making arrangements for storing. Conditions in the Rocky Mountain States and on the Pacific Coast remain normal and unchanged.

Boston, Mass.

The interruptions to transportation, following closely upon the holiday suspension in mining, have materially affected the Eastern situation, and an active market has prevailed. Stocks are lighter than at any time so far, and prices of bituminous at all points are correspondingly higher. The heavy demand for contract coal shows no let-up and practically no spot coal is for sale.

Bituminous all-rail is now coming through slowly. Cars are short and the better grades from the Pennsylvania districts are practically out of the market.

In anthracite the production is apparently far behind the demand. In what is ordinarily a slow season we find orders entered six weeks ahead, and the outlook is rather complex. The companies are short of all sizes, and some of the individuals all-rail are getting prices from 25@50c. above the circular on stove and chestnut. On Jan. 22, the Boston retail dealers advanced chestnut from $7.50 to $7.75, screenings from $2.75 to $3, and soft coal, net tons delivered, from $4.50 to $4.75.

Water freights are unchanged, $1@1.10, Virginia ports to Boston. A rate of 80c. was paid this week, New York to Providence, establishing a new record on the sound.

Current prices are as follows:

Clearfields, f.o.b. mines	$1.20@1.45
Somersets, f.o.b. mines	1.30@1.50
Pocahontas, New River, Boston, on cars	4.25@4.75
Pocahontas, New River, Providence, on cars	4.15@4.50
Pocahontas, New River, for shipment, f.o.b. Hampton Roads	2.70@2.75

New York

The market here is now very firm. Reports of poor car supply are heard on all sides and the railroad movement to tidewater is unusually slow. Consequently the stocks on hand at the piers are considerably reduced and the better grades of coal are almost without exception out of the market. There is a strong demand for high-grade steam coals and shippers handling these grades have turned down considerable business offered them this week, because they have not been in a position to take care of obligations already booked and consequently are not able to take on additional business.

Inferior steam coals can be secured without much trouble and although there is not much tonnage of this grade of coal on hand at the piers, it has been possible to buy West Virginia steam coals this week at from $2.50 to $2.60 f.o.b. while ordinary Pennsylvanias have been offered at $2.65 to $2.70 f.o.b.

Loading at the piers is still slow on account of frozen coal but one warm day was experienced this week which was of great assistance to the piers in enabling them to catch up on their orders. Loaded boats have not been so much in demand but it is reported that a few have been sold on the basis of about $3 alongside for ordinary grades.

Consumers along the line are beginning to feel the effects of the slow movement on the railroads and an increase in orders is a result of this condition.

Philadelphia, Penn.

The retail trade in this vicinity still continues to be of the best. The week started in with very seasonable weather, a snow storm followed by a coating of sleet, thus adding to the dealers' troubles. There has been no apparent diminution in the demand for all sizes, and the cry of the dealers is that they cannot get the coal. Stove, chestnut and pea still continue as leaders, with a good demand for egg and the other sizes. As a matter of fact, many house holders have been compelled to use egg size, in the absence of stove or chestnut, it being impossible for them to wait until the dealer could furnish what they wanted. The ending of January is in marked contrast to that of the same month a year ago, as at that time, retail trade had commenced to lag a little.

The wholesale trade still enjoys a period of prosperity. As one large operator put it, conditions are about the same as if the strike were already on and dealers have sufficient orders booked to cover the output for February. There is no cutting of prices by the individual operators and prices are stable for all kinds, with the possible exception of the smaller sizes, for which a premium is being asked and received. Buckwheat, which has not always found a ready market at this season of the year, is moving freely, and it is necessary for some of this coal to be picked up from stock. Taking altogether, the wholesale market has an excellent outlook for a month to come, at any rate, and after that, the fear of trouble at the mines will be a controlling factor.

The bituminous trade still continues to be anything but favorable. Good coal is being offered in the market at concessions, and few takers at that.

Pittsburg

Bituminous—Wage - scale negotiations at Indianapolis, in connection with the annual convention of the United Mine Workers, are purely perfunctory, neither side having had the least expectation of

an agreement being reached. The operators have demanded a reduction and the miners an advance. The technical position is that the miners caucused last night, formally deciding there was no chance for the operators' demands to be accepted. Today the joint conference will probably turn the question over to a sub-committee, to see if a basis for negotiation can be reached, and as no such basis is likely to be found, a disagreement and adjournment will probably occur before the end of the week.

Nothing has occurred, and nothing is likely to occur, to change the original prospect, which was that there would be a suspension of mining, lasting perhaps six weeks from Apr. 1, by which time a compromise would probably be reached on substantially the present scale.

Mines have operated more steadily, the weather being better and the demand good. Consumers are about ready to begin stocking up, in anticipation of a suspension, and this should keep the mines operating nearly full for the next two months. Prices are steadier since the disturbance due to the cold snap. We quote: Nut, \$1.05@1.10; mine-run, \$1.10@1.15; ¾-in., \$1.20@1.25; 1¼-in., \$1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg district.

Connellsville Coke—Despite continued expectations in some quarters that the end of the holiday period and the end of the extreme cold snap would bring a reaction in coke prices at least part way to the level which prevailed at the beginning of December, prices are as high as ever. On Friday, 1000 tons of prompt furnace coke was sold at \$1.90, and the market continues to be quotable at \$1.85 to \$2, depending on tonnage, etc., there being minor variations from day to day. Two contracts are reported in the past week, aggregating 15,000 tons a month, February to June, inclusive, at \$1.85, which is about the average of what can be done on various grades. We continue to quote: Prompt furnace, \$1.85@2; contract furnace, \$1.80@2; prompt foundry, \$2@2.25; contract foundry, \$2.10@2.25, per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Jan. 20 at 407,185 tons, an increase of 16,000 tons, and shipments at 4526 cars to Pittsburg, 5858 cars to points West and 887 cars to points East, a total of 11,271 cars, an increase of 1900 cars.

Baltimore, Md.

Notwithstanding the fact that there was a decided change in weather conditions here, there is still a rather pronounced activity in the Baltimore market. The demand for coal continued good, and prices remained firm.

Unfortunately, movements from the mines in West Virginia and Maryland are not at all satisfactory. There is also congestion at the port of Baltimore on account of the large quantity of ice which is still found in the Patapsco River and Chesapeake Bay. Fuel is still being received at the railroad piers here in a frozen state, and as before stated, this retards a quick movement. Hundreds of cars received during the past week could not be unloaded until they had been put through the steaming process, which requires time.

Buffalo, N. Y.

The bituminous situation is a little stronger, though the improvement in price is entirely confined to slack. Several shippers state that they have lost good customers within a few days by asking 5 or 10c. more on other grades. One shipper, who complains of slow service from the railroads, undertook to advance the price on the promise of quick delivery, but unless the buyer was entirely out he was uniformly refused.

This unsatisfactory condition of prices is discouraging, especially in view of the near future of the trade, with the miners clamoring for more pay and the contract season coming on. Dealers are declining to make any contracts and they may be obliged to stay out of that market for months yet.

This market is holding its own in the outlying districts, no innovations being reported for some time. There is more Canadian coal on the market in the eastern section of the St. Lawrence district than there used to be, but the consumption is still increasing quite fast. The movement through the state is good, but shippers to tidewater mostly complain both of orders and of the scarcity of ocean tonnage.

The price of bituminous continues the same for sizes, but with slack quotable 25c. higher. Pittsburg three-quarter is \$2.50; mine-run, \$2.40; slack, \$2.25, with Allegheny Valley about 25c. less. Coke continues to improve slowly, but prices are the same, on the basis of \$4.25 for best Connellsville foundry and \$3.50 for stock coke.

The anthracite trade is strong, the severe weather alone being sufficient for that. The stove size is still scarce and chestnut is short. Already stove is giving out in the West and there is complaint that since the holiday season there have been conditions to hinder full work at the mines. The weather has interfered with production of late, the Pennsylvania mines generally reporting record cold weather much of the time in January.

Cleveland, Ohio

Conditions during the past week in this market have materially changed, owing to milder weather prevailing. There has, however, been a steady demand for domestic lump, and a much better call for mine-run, with prices from 10 to 15c. per ton in advance of two weeks ago. On account of the large quantity of lump coal being mined, slack prices have decreased from 10 to 15c. per ton, and a congestion of slack in this market has been evident during the past week.

During the severe weather some three weeks ago, large orders were placed for domestic lump, as well as mine-run, for steam purposes, and also slack coal. Owing to the snow blockades, railroads were unable to deliver promptly to the different markets in this section, and when they could handle this coal, large quantities arrived at once, especially that of slack. The domestic coal and mine-run were quickly bought up, but the slack became a drug on the market, so that prices were reduced in consequence.

Operators are holding up firm on Ohio slack at 90c.; Middle district, 95c.@\$1; Pittsburg, \$1; West Virginia, from 65 to 75 cents.

In the outlying districts, large manufacturers are taking in all the slack they can conveniently handle (also the large steam users in Cleveland) in preparation for the probable strike in the bituminous and anthracite fields.

Columbus, Ohio

While the weather has moderated to a certain extent and railroads are not materially delayed, still coal shipments are in a demoralized condition and operators, jobbers and retailers are suffering as a consequence. Railroads have been unable to move large shipments of coal promptly and in some instances cars have been delayed on the road from three weeks to a month.

The greatest trouble in railroad shipments is with the connecting lines and not with the initial carriers although the latter are in pretty bad shape. On the Hocking Valley Ry. the equipment is better than on other coal roads of the state. The B. & O. and T. & O. C. appear to be in bad condition.

The Hocking Valley district is probably producing a larger tonnage in proportion than any other part of the state. In eastern Ohio the output is below normal and the same is true of the Pomeroy Bend and Crooksville districts.

Prices continue to rule strong in every variety. Fine coal is still the strongest point in the market and prices are slightly higher than a week ago. It is almost impossible to secure any quantity of nut, pea and slack and coarse slack although West Virginia is helping out the market to a certain extent.

Considerable inconvenience has been caused steam users in the delayed shipments and some manufacturing plants were compelled to close down because of lack of fuel. Consumers in the rural districts have also suffered to a large extent.

Prices prevailing in Ohio during the week were:

Domestic lump in Pomeroy Bend district	$1.60@1.75
Domestic lump in the Hocking Valley	$1.50
Three-quarter inch	1.35
Nut	1.15
Mine-run in eastern Ohio	0.95@1.05
Mine-run in the Hocking Valley	1.05@1.15
Nut, pea and slack	0.75@0.85
Coarse slack	0.65@0.75

Cincinnati, Ohio

Improved river conditions within the last few days have materially lessened the tension as to lump coal in this market. All other conditions affecting the trade have remained practically unchanged, with the result that the total change in the general coal market is not marked.

Traffic conditions—that is, as to rail transportation—are as unsatisfactory as ever. These unfavorable railroad conditions have been in evidence ever since the beginning of the year, since which time present improved market conditions, as to demand and prices, have been in effect. Probably at no time during last year was there an entire month as satisfactory as the January just closed was. Unusually severe winter weather kept the domestic demand at the top notch, and was a factor in the steam-coal demand also, since a large amount of nut and slack is used in steam-heating plants in practically all the buildings in the city.

The weather has moderated considerably, but the demand seems to keep up—from the impetus of the previous weeks, if nothing else. There is practically no spot coal to be had now, and conditions are the exact opposite of six weeks ago, when there was an immense amount of fuel on cars. Prices keep up and the indications are that with a little more of winter weather there should be no serious set-back to the market for a long time.

Charleston, W. Va.

Car supply is still the obstacle in the way of increasing the output in the West Virginia fields. This is due to the congested conditions along the railroads, both in the East and West, but there are more complaints coming from the West than in the East. The snows and bad weather have made the movement of trains difficult, and, although there has been an improvement in weather conditions, it has not been of sufficient duration to enable a resumption of work at the mines, because the empties are not yet coming back in quantities.

The output will probably be 30 per cent. under December. Tidewater shipments are reported to have been slightly improved during the past few days. The Virginian Ry. is reported to be handling matters at Sewell's Point without great difficulty, and improvement is reported from Newport News.

Memphis, Tenn.

Memphis has had a new experience in the last two weeks; it has broken the weather record as far back as the memory of the oldest citizens, inasmuch as the thermometer went below zero twice in the same week. Such weather caught the smaller dealears of this territory practically without coal. However, the larger dealers were well stocked and able to take care of the situation.

The mines which supply Memphis territory are now demanding and getting better prices than they have been able to get for the past two years. Wholesale prices at the mines are as follows:

Kentucky lump	$1.50@1.75
Nut	1.00@1.35
Mine-run	1.00@1.15
Alabama lump	2.00@2.50
Alabama nut	1.75@1.90
Jellico	2.00@2.25
Jellico block	2.25@2.50
Cahaba coals	2.50@3.00

As usual the southern cities, particularly Memphis in extremely cold periods, did not advance the price of retail coal, our prices remaining the same as prior to the extremely cold weather; that is, as follows:

Kentucky lump coal	$4.00
Kentucky nut	3.50
Alabama	4.25
Jellico	4.75
Cahaba	4.75@5.00
Screenings	2.10@2.65

Nashville, Tenn.

One week of pleasant weather has helped in a measure to relieve the situation which a week ago looked critical, although the car shortage has improved but little, and supplies are still short in the cities.

Another cold spell of weather, with an inadequate supply of cars, will place this field in nearly the same condition it was in a week or 10 days ago. It is a weather market pure and simple. The dealers are trying to place themselves in the position of not running out of coal during February in case of a protracted spell of bad weather; consequently they are ordering in large quantities.

Indianapolis

The alleged holding of coal cars by the railroads during the cold weather, made it impossible to get Indiana coal to the market. This resulted in increasing the price on an average of 25c. a ton, and the subsequent spasmodic movement, has all occasioned the markets to be well supplied, but the advance price is still maintained.

The operators and coal dealers blame the railroads for these conditions, while the railroads say they ran out of engines and could not keep the engines they had from freezing. The Duane yards, a great distributing point near Terre Haute, was jammed with coal cars which could not be moved until the railroad commission took a hand and insisted on its going forward. Nearly 800 cars were side-tracked at Clinton, and were not moved for about a week. The operators had both the orders and the miners to run full time, but now the mines are being operated only two or three days per week.

Chicago

Softened prices are prevailing in Chicago, the market having fallen about 25c. on prepared sizes of coal and from 25 to 50c. on the fine coal.

Transportation service by the railroads has been unusually poor. The Erie R.R. has had 2000 cars of coal at two junction points which it could not move and the Illinois Central has done comparatively little toward moving coal. Smokeless has been governed by the transportation situation. It would be comparatively easy to get $2.25 to $2.50 for lump at the mines if there were any for sale. The supply of screenings has been just about equal to the demand. The high-grade screenings have been selling from $1.25 to $1.50 at the mines, while medium grades command from $1.15 to $1.35. There has been an exceptionally keen demand for anthracite, and coke is strong at previously existing prices.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.62@2.87
Steam lump	2.37@2.62
Screenings	2.02@2.22
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.32@2.57
Mine-run	2.32@2.57
Screenings	1.82@2.32
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.27@2.52
Mine-run	2.27@2.52
Screenings	1.87@2.12
Pocahontas and New River:	
Mine-run	$3.15@3.30
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.50@4.65; byproduct, egg and stove, $4.85; byproduct, nut, $4.55@4.65; gas house, $4.85.

Minneapolis—St. Paul

Unexpected in a large measure and more or less unaccountable has been the demand in the Northwest for the month of January. Dockmen say never before has the demand been so heavy at the head of the lakes. The temperature for the month has been the lowest in history for the Northwest and many towns would have suffered coal famines if the retailer had not been loaded with supplies when the severe weather set in. As it was, small towns on the stub and branch lines have sent in urgent appeals for help and railroads have been forwarding special trains.

At this writing the exact shipments have not been announced but it is estimated that 50,000 cars of coal have been sent out from Duluth and Super-

ior this month. The retail trade is, of course, unusually busy and teams are reported scarce. No change in the retail price has been made.

St. Louis, Mo.

Conditions opened up quite favorably the early part of the week, although the closing of last week brought prices down to the level they had been before. Last week closed with Carterville egg and lump at \$1.50, nut at \$1.35, and screenings at 70@85c. Mine-run was bringing from \$1.10@1.20. The news from Indianapolis this week has caused some comment, and a great many of the manufacturing plants are arranging for storage facilities.

Standard coal got down to as low as \$0.95@1 for 2-in. lump, but, with the beginning of this week, both the Carterville and Standard coals showed an inclination to move upward. Mount Olive, while starting off at \$1.75 the early part of last week, went down to \$1.50 and started off the early part of this week at the same figure.

The smokeless market is good, but the coal is hard to get in, and prevailing prices here are \$1.50 for mine-run, and \$2.25 for egg and lump, with a \$2.50 rate. The demand for anthracite has been exceedingly good, but there is little moving in, although plenty has been ordered, and chestnut and stove sizes are rather free. Coke has been in exceedingly good demand at \$4.75 for gas house and \$4.90 for byproduct.

One mine in the Herrin district reports not having any Illinois Central cars between Jan. 5 and 26. Last week several mines in the Standard field only had a half-day's work. The Iron Mountain and Frisco have done remarkably well this winter, and prospects are that they will continue to do so, but there is absolutely no hope at all for conditions bettering on the Illinois Central. The roads in the Standard field are giving good service—have plenty of motive power and equipment, although they have restrictions on the latter.

Spokane, Wash.

The cold weather which has been prevalent in the Northwest for the last week has moderated to such an extent that the coal sales have been reduced very materially. The stocks in the yards of the local dealers are plentifully supplied, and are being increased daily with shipments from the mines.

The prices remain the same as they have for the last two months. Several towns in Southern Canada and in the mountains have had a scare about a fuel famine on account of the blockades on the roads in the mountains. However, they seem clear now and no shortage is expected in this section of the country during the balance of the winter.

Portland, Ore.

Mild weather is still prevailing here, and the demand for coal continues light. The Southern Pacific Ry. this week announced reduced rates on fuel oil to points south of Portland, and this will probably mean the consumption of larger quantities of oil to the detriment of the coal trade. The reduction ranged from 15 to 30c. per barrel, according to distance. The announcement was made that the reduction was brought about in order to stimulate manufacturing. Loggers and lumber manufacturers will draw the greatest benefit, as they have introduced oil fuel for donkeys and logging-road locomotives, because of less danger from spark fires.

Production and Transportation Statistics

Pennsylvania R.R. Co.

Statement of coal and coke carried by the P. R.R. Co.'s lines east of Pittsburg and Erie for December and year 1911.

	December	Year	Increase or Decrease
Anthracite..	1,214,805	11,[illegible],149	+360,916
Bituminous..	3,981,486	42,[illegible]19,445	+921,533
Coke.......	910,971	1[illegible],639,107	—2,183,588
Total.....	6,107,262	65,015,701	— 901,139

The Virginian Ry. Co.

The total shipments over the Virginian Ry. for December, 1911, were 258,869 tons.

The Baltimore & Ohio R.R.

The coal and coke shipments over the lines of the Baltimore & Ohio R.R. for the month of December, 1911, and for the same month of the previous year, were as follows, in short tons:

	1911	1910
Coal..............	2,468,943	2,409,710
Coke..............	313,821	314,545
Total...........	2,782,764	2,724,255

The Car Situation

On Jan. 17 the net surplus of idle cars on the lines of the United States and Canada stood at 90,285 as compared with 135,938 two weeks before, a difference of 45,653.

In the two weeks ended Jan. 17 the surplus of coal cars decreased from 64,719 to 42,770 and the surplus of box cars decreased from 36,145 to 23,111. Surplus of miscellaneous cars decreased about 5000, but the number of idle flat cars remained the same as in the last report.

Foreign Markets

Great Britain

The market is dull and several Admiralty descriptions are a little easier for prompt shipment. For forward loading most sellers prefer to hold. Quotations are approximately as follows:

Best Welsh steam coal..........	\$4.68@4.80
Seconds....................	4.50@4.62
Thirds.....................	4.20@4.44
Best dry coals..............	4.26@4.38
Best Monmouthshire..........	4.26@4.26
Seconds....................	3.96@4.02
Best Cardiff small coals........	2.52@2.64
Seconds....................	2.34@2.46

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days less 2½% discount.

Cuba

Exports of bituminous coal from the United States to Cuba for the year 1911 were valued at 2¾ million dollars as compared with 1¼ million for the year 1903.

Financial Notes

The coupons due Feb. 1, 1912, of the first mortgage sinking fund 6% gold bonds of the Central Iron & Coal Co. will be paid on and after that date.

Over 80% of the Cumberland Basin Coal Co.'s first and second mortgage bonds has been deposited with the Safe Deposit & Trust Co., of Baltimore, depositary under agreements dated Dec. 13, 1911.

The Dominion Iron & Steel and the Dominion Coal Cos., at recent meetings, each authorized the issue of \$3,500,000 of income bonds which they are authorized to exchange for the preferred stocks of the Dominion Steel Corporation. A resolution was passed confirming the previous resolution to issue 70,000 preference shares to the value of \$7,000,000.

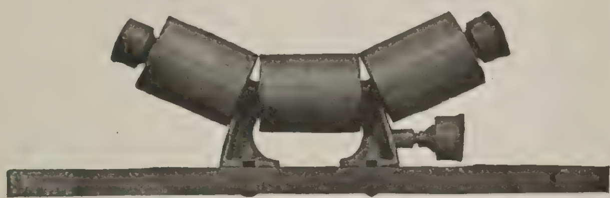
The City Fuel Co., Chicago, incorporated in Illinois as the Reliable Fuel Co., changed its name on Nov. 10 to City Fuel Co., and increased its capital stock from \$5000 to \$4,200,000, all outstanding (par of shares \$100), consisting of \$2,000,000 common, \$2,000,000 cum. 7% pref. and \$200,000 cum. 6% sinking fund pref., this last being retirable \$30,000 yearly out of earnings. No bonded debt.

With the further rise of Jersey Central to 337, a new high record, financial circles have become convinced that the time for a division of that road's coal properties is near. Jersey Central owns 97%, or \$8,491,150 of the \$9,212,500 stock which the Lehigh & Wilkes-Barre Coal Co. has outstanding. Disregarding the 3% minority interest, the Jersey Central could capitalize the assets of the coal company at \$27,436,800, and give the railroad's shareholders a dividend of 100% in stock. On such a capitalization the coal company could earn practically 8%, as its yearly income for dividends can conservatively be placed at over \$2,200,000.

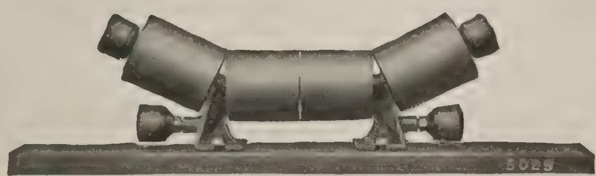
Reorganization of Rhode Island Coal Co. will probably be effected by forming a new company. Present company has 500,000 shares authorized, of which 420,000 are outstanding. Holders of floating debt amounting to \$575,000 will probably take new stock at \$3.50 per share. If the plan is carried out the new company will have \$500,000 cash after payment of floating debt. In the reorganization President Henry M. Whitney, as owner of substantially all of the company's floating debt of \$575,000, virtually offers to accept in settlement a trifle less than 60c. on the dollar. On sales of several thousand shares, this stock broke recently on the Boston Curb Exchange to a new low point of 33c., off 12c. from the previous close. Fears of a heavy assessment are supposed to account for the renewed selling.

"Link-Belt" Belt Conveyors

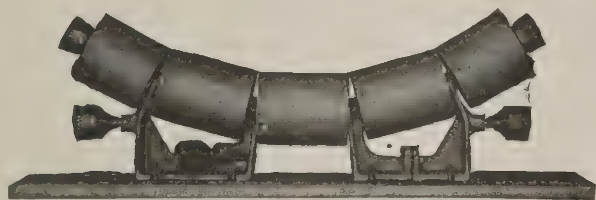
We have manufactured and installed Belt Conveyors for purposes for which they were suitable for upwards of 20 years and are furnishing the most efficient and durable equipment to-day.



Standard 3-Pulley Idler. (Patents Pending)

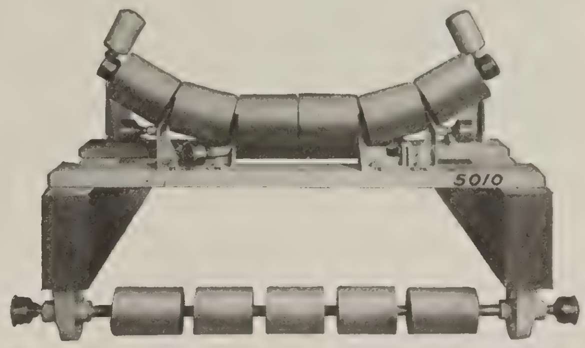


3-Pulley Idler. (Patents Pending)



Standard. 5-Pulley Idler (Patents Pending)

3-Pulley Type Belt Conveyor



48-in. Idler with Guide and Return Rolls. (Patents Pending)

Pressed Steel Idler (Patented)

We Design and Build

Elevators and Conveyors for the efficient and economical handling of materials of every description.

Catalogs upon request.

ALBANY LUBRICATING COMPOUND O EZR IC

What Lubricant will you use on your engine?

Will you buy some "just as good" lubricant, because some theory seems to prove that it ought to be a good friction reducer?

Or will you spend your money for a lubricant that you know to be good? One that has been thoroughly tried and proved?

ALBANY GREASE

ALL LUBRICANT—NO WASTE

is first, last and above every other lubricant on the market, of absolutely known worth.

Don't keep on using the wrong lubricant in the wrong place. Send for a free copy of our new book, "Death to Friction," and get straightened out.

ALBANY LUBRICATING CO.

Adam Cook's Sons, Props.

Washington Street New York

Why Take Chances

WHY take any chances by putting anything iuto your mine that will burn, if you can help it.

Cotton duck burns easily.

No waterproof Brattice Cloth is fireproof.

The treatment to make it withstand water renders it *more inflammable.*

Kern's Non-Inflammable Brattice Cloths

closely woven, and made of hard twisted yarn,

Will serve better than a waterproof cloth.

Protects your mines from the menace of fire through loose threads taking fire from open lights or sparks.

It is a good air conductor; allows a minimum seepage of air.

Does not rot readily. Is flexible and easily handled in the shafts and mines. Strongly made, and holds well on the nails. The price is reasonable. Cheaper than most Brattice Cloths.

Kern Commercial Company
114 Liberty St. New York

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—An electrician for a coal mine in southwest Virginia; must be able to wind armatures, understand mining machines and be able to look after steam and electric plant; in answering state fully experience and salary expected. Va-Lee Company, St. Charles, Va. Feb. 24.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—Position as mine foreman or assistant superintendent; have had 25 years' experience in West Virginia and Ohio coal; have filled all positions from trapper boy to mine foreman; desires position in West; can give references. Address Box 10, Coal Age.

C A

COAL AGE

Vol. 1 NEW YORK, FEBRUARY 10, 1912 No. 18

ONE of the greatest hindrances to success in mine management is the lack of close observation on the part of officials. The original man is to be admired, and initiative should be commended, but the fellow worth while is the one who can supplement such virtues with an ability to cull the best ideas from everyone with whom he comes in contact.

And by observation, we don't mean simply a casual glance that only records the fact and fails to analyze the cause. Thousands of people had seen the cover of a tea-kettle forced up by steam, without pondering the occurrence, but to Watt the phenomenon meant something, and he was soon busy applying his ideas to perfecting the steam engine.

Perhaps a million people, before Archimedes, had observed water run over the side of a vessel when another substance was immersed in it, but no one had sufficient curiosity or ability to examine the matter in detail and give the world the laws of specific gravity.

A close observer can learn from the mistakes of the uninformed as well as from the correctness of the wise. We don't always have to visit the most modern plants to secure ideas that will help us at home. Frequently, much benefit will be derived from watching some other fellow give a demonstration of "how not to mine coal."

Success of one kind or another is what we are all striving for, and no one element is so indispensable to a prosperous outcome as attention to details. Truly! great deeds excel great thoughts, and all of us like to plan big things, but we lose enthusiasm when confronted with the drudgery of cleaning up the minor particulars. The manager of a coal mine may be brilliant, but if among his defects is included an incapacity for the small essentials, then in truth he is like the dancing master who had every qualification except that he was lame.

Recently, in COAL AGE, one of our most famous geologists called attention to the vital necessity of making a careful examination of coal measures before concluding final plans and starting development work. And few of us but know of the sorry mess some men have made in the location of a shaft or drift, when a careful analysis of the original situation would have saved the operating company thousands of dollars in pumping or haulage.

You say you are observing! Well, stop one minute and ask yourself how many steps lead up to the door of your house, or how many letters there are in your name. You've climbed your steps every day for a year, and written your name thousands of times; still your observation was entirely general. Hasn't it been just as superficial when you walked about your plant and through your mine?

Of course, you know the number of men you employ and their daily output of coal; the quantity of water to be pumped and the volume of air required—chief items that affect daily expense. But how about the lesser details—waste of timber, iron, nails, oil and other supplies; cost of steam, charges against mine-car repairs, loss of electric power through poor rail-bonding and defective insulation, resistance of cars to traction—these are a few of the leaks that drain the exchequer.

Successful men have been remarkable because of their minute attention to small things. Like the elephant, they can move colossal masses or pick up a pin. The difference of intellect in men results more from a cultivation of the habit of attention, than from any great disparity between the mental powers of one individual and another.

Furthermore, our interest in things about us always increases in direct ratio with our knowledge of them, and our knowledge results largely from close observation. No man is less brilliant in the great things of life because he pays attention to the lesser essentials. Details are the mortar which binds the great walls of our daily operations.

Determinants of Coal Thickness

By R. Dawson Hall

Structural rolls in strata may be coeval foldings. If so, they will modify thickness; if noncoeval, the coal will pass over the anticlines and synclines without change. The thickness of a peat bog under pressure decreases as the cube of its linear dimensions. Some increases in thickness are due indirectly to erosion.

As the coal thickness depends in some degree on the structure of the measures of which it forms a part, a few preliminary words on that structure may not come amiss.

The structural rolls in strata may have been existent or developing when the strata were laid down; such rolls we term "coeval." Many were developed from stresses more recently imposed on the measures; for instance, the Appalachian coalfields were slightly rolled during the time the coal was being deposited, but later a severer stressing took place, known as the "Great Uplift." The first flexures we know as "coeval" rolls and the latter as "non-coeval." The Pittsburgh bed shows the former rolls not nearly so plainly as the beds of the Allegheny series. Probability favors the idea that it was laid down during a period of profound rest, when the motion of the measures was slow and of like sign, up or down, over large areas.

Not so was the condition during the deposition of those beds we class together under the caption "Allegheny," nor even in the time immediately following the laying down of the Pittsburgh Bed, when the pre-Sewickley rock and the Sewickley coal bed were deposited. Frequent rolls and constant variations of thickness mark the Allegheny or Lower Productive coal series. The variations of thickness will make a bed like the upper Kittanning run from 14 ft. to 2 ft. in a furlong of horizontal distance.

The lower Kittanning and the Freeports give reassuring thickness in the coeval depths followed by thinnings on coeval hilltops. It is the lack of recognition that all dips and hills are not coeval (that is existent when the coal was deposited) which has caused many people to formulate the untenable theory that coal thickens in all dips and thins on all domes and ridges and to be disappointed in the showing made by coal beds in dips where the folding occurred after the coal was lignitic or even of harder structure.

The Dips of the Allegheny Series.

The directions of the folds of the Great Uplift vary from 10 to 45 deg. east of true north, whereas the folds of the Kittannings in the Lower Productive series are almost due east. There is no mistaking the existence of the latter for, where the measures are flat, they can be traced in the lower and upper Kittanning beds for miles. The basins are 30 ft. deep and over, in many places, and have side-slopes with 6 to 10 per cent. grades. The coal thins as soon as the rises are encountered. A field of coal, which ran almost uniformly 30 in. in thickness, showed 4 ft. in a long dip running across it. The basin occurred in the lower Kittanning bed and was very regular, both in line and thickness of deposition except where such dips occurred.

I am well acquainted with the bed just mentioned and it is invariably crossed by these little synclines, which, strange to say, often affect the cleat of the coal as much as 15 degrees. These dips do not

Fig. 1. Crossing of Structural Folds

appear to reproduce themselves infallibly in the Freeport measures above. The dips in those beds seem to be less continuous, and rather of the bowl-shaped order. The shrinkage of the Kittanning peat beds must have been very complete before the Freeports were laid down or the dips in the former would be immediately overlaid by those in the upper bed and would be coterminous with them, which does not appear to be the case.

The whole subject needs careful study where both beds are being worked, but unfortunately, in the region where both are operated, contouring of the coal floor and the use of superposed maps is not usual, the interval being great enough and sufficiently strong to make columnization of the pillars unnecessary, with the result that correlative mapping is not appreciated. Moreover, the beds are thin and caving is rarely complete.

Coeval Dips are Often Disguised

In view of the shrinkage of the lower beds and their failure on the whole to influence the surface on which the Freeports were laid down, we must expect to find the interval increased where the coal thickness in the lower bed is greater, if meantime other foldings do not occur to modify conditions.

It must be remembered that, when in crossfolding a minor dip is elevated to the flank of a larger fold, that minor dip may cease altogether to be a dip, as shown in the Fig. 1 at *G*, and become merely a decreased rise, but its original existence as a dip may not be gainsaid. Moreover, the effect of the coeval hill crossing the cross section at *D* is to move the apparent location of the syncline of Great Uplift at *E* to a point *F* nearer the flank of the anticline.

It is, of course, true that the Federal maps show structural contours which are, in a measure, really the composite result of all flexure and not merely of the Great Uplift, but in central and southwestern Pennsylvania, at least, the lines mainly exhibit that great convulsion and not the smaller crossing curvatures. Farther west the charted synclines are more contorted as they combine in one, the past with the remote past. There the flexures are more equal. It seems a pity that an attempt is not made to record these coeval flexures, tracing their progress from quadrangle to quadrangle. Structurally not so evident, economically they have even a larger value. And it might be not amiss here to suggest names for such coeval synclines and anticlines whether they be coeval with coal or coeval with other sediments. Such synclines might be termed "vallines," and such anticlines "collines."

The Law of Shrinkage.

The only basins which effectually modify the thickness of a coal bed are those basins the formation of which is coeval, or approximately coeval with the deposition of the seam. Where coeval, the peat probably filled the basin so that it was level with that on the undepressed portions or on the anticlines. But the peat has shrunk considerably. Still the peat residue covers the original area but its thickness has been reduced in proportion to the cube of the lateral reduction. If a cubic yard has shrunk to one-third of its former linear dimensions, the thickness of a cubic yard has become 1/27 of its former thickness for the lateral spread has in no way changed, this spread being maintained constant as a result of superincumbent pressure and friction.

Fig. 2 labors to make this fact more obvious. The cube on the left represents a cubic yard and that on the right the same cube shrunk in three directions to one-third of its former linear dimensions.

The little strip marked off on the large cube at its base shows to what diminutive proportions vertically that cube will be reduced when the vertical dimension is shrunken to such a point that the volume of the strip is equal to the volume of the cube to the right. The depth of that strip will be but 1/27 of the full height of the original cube.

This fact makes it hard to account for variations of thickness such as the middle and upper Kittanning beds exhibit, in valleys unequal to such depths of deposition as would account for such variations. Many theories might occur, either that the bogs slid into place from a distance after they had already been subject to a large amount of shrinkage, or that the time of deposition was so long that the lower layers were well contracted before the upper were deposited and that was doubtless true in almost every case, or that the deeper portions of the bog shrinking more than others, drew away portions of the shallower. We may dismiss as wild the suggestions that these peats shrank less than others because they are often of cannel and, therefore, have a pore-like structure and the amount of ash is not excessive. It appears probable that the first surmise is correct as the beds are by no means reliable consisting often partly of cannel and partly of ordinary bituminous coal.

Nevertheless, the shrinkage of the bog during deposition and the consequent fluid movement, must often have modified its depth where the floor on which it lay was uneven.

Possible Decrease of Thickness in Dips

Rolls in the strata, occurring later, folded them, but did not change their thickness, but if a heavy deposit of silted material should fill up the depressions of these rolls, then there would be more pressure in the dips, and any plasticity in the peaty coal would cause it to flow away from these synclines toward the anticlines adjacent.

The action would not be marked, because of the little plasticity remaining in the coal, its naturally fibrous condition, the friction of its contacts, and the fact that the motion is against the operation of gravity.

It is for this reason that we look for thick coal, not where the charted synclines appear on the Federal maps, for these large synclines are to be dated thousands of years later than the coal depositions, but to those uncharted synclines of even date with coal depositions, concurrently created with the growth of the coal forest.

To use the Georges Creek field as an illustration: The coal in the bottom of the basin at Consolidation No. 10, the former main pumping shaft, is not thicker than the coal which lines the slope of the syncline. But as we go southward up the southern end of the canoe-shaped fold, the coal gets thicker, and all the intervals grow larger, because the southern end of the field suffered a depression during the coal era, which was more than negatived in places by contrary and cris-cross flexure later. But the original folding, while scantily modifying the final lie of the Pittsburg coal, made a modification of 4 to 6 ft. in its thickness. This action is not peculiar to Georges Creek; in countless places it is exhibited in larger or smaller degree over the whole earth's crust, carboniferous or non-carboniferous.

Coal Thickness in Anthracite Region

This consideration is not addressed to those engaged in anthracite development. Having seen plications of great magnitude and coal, thickening and thinning without regard to them, the hard-coal geologist would entertain no such fallacy as appeals to the operator of the Allegheny series of bituminous coal-beds, to wit that "where there is a dip, there thick coal will be found." It will be recalled that it was in a bituminous field, in Elk county, that Leslie and Ashburner, of the second Geological Survey, found it necessary to declare that the anticline coal was as thick as that of the syncline.

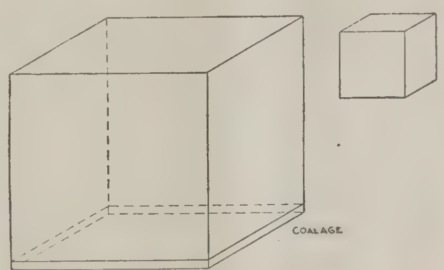

Fig. 2. Diagram Illustrating Restrained Shrinkage

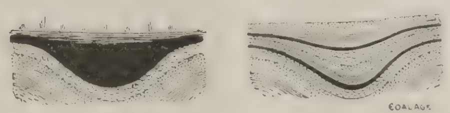

Fig. 3. Showing Peat During Formation, and After Shrinkage

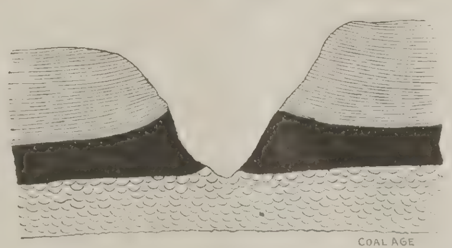

Fig. 4. Coal Beds Thickening toward Stream

The coeval and near-coeval dips probably exist in the anthracite region, but are only faintly to be discerned where such violent upheavals have occurred. In fact, an anthracite expert would be prone to say dips do not control thickness because the larger foldings, the only foldings which the present conditions permit him to identify, are not marked by a change in bed-content.

Hence we do not seek for thick coal in the more recent and major plications, but in those which date their rise to the period either prior to the deposition of the coal, or contemporaneous therewith.

Erosion and Coal Thickness.

And again there was another cause of coal thickening, not inoperative to-day, when the seams are but little subject to plastic flow, but very much more operative when the peat bog yielded freely to every inequality of pressure. To-day we often find that where recent erosion has relieved large areas from pressure, where valleys 400 or 500 ft. deep have been carved in ancient measures, there has been a flow of all plastic bodies, bituminous coal, clay, and soft shale toward the outcrop. There these beds are thickened, though often partly washed thin again, where the very edge of the measure is reached. Far more, where erosion has developed soon after the deposition of carboniferous strata, the plastic measures have moved in part toward the unstressed or less stressed areas, to pile up along the outer lines of the eroded districts. The sandstones and slate were then more feeble to resist the powerful stresses of such fluxions and lipped up freely near the edges.

And thus we find an eroded area, a fault, we term it, of erosion, lined out significantly with areas of thicker coal and clay, surmounted by weakened slate and sandstone.

Where erosion has been extensive, the peat bog may be lifted and deposited during floods at some distant point, or even over the same seam, making a very thick bed with or without a binder. When redeposition takes place, the speed with which the fibrous mass is thrown forward may cause the resulting coal to lie at a sharp angle, the rapidity of its motion thrusting the upper end far up above the level of the water conveying it.

All portable mine pumps should be used with motors which can be thrown directly on the line without the use of a starting device, and without taking an excessive current. In case the power fails temporarily, such motors start themselves when it returns. All switches for use with such motors should be properly fused.

Needless Waste of Grease and Oil

By E. L. Cole

Grease and oil can be saved if a scientific examination is made of the needs of each part lubricated, and if a proper sense of responsibility is created among oilers. A series of forms publicly posted will call general attention to the efficiency of each man's use of the oil entrusted to him.

The general manager of a large coal mining company paused as he was about to affix his signature of approval to the ever increasing oil bill of his corporation, and as he looked over the bills for the previous ten months he came to the conclusion that here was a financial leak that could possibly be stopped. He detailed a young clerk in his employ to ascertain if possible, how the worrisome oil bill could be reduced without detriment to the well being of the machinery. Early on Monday morning he started on his tour of inspection to various collieries, his first stop being made at a fan engine-house: Taking out his stop watch, he carefully counted that in one minute 110 drops of cylinder oil entered the chest of the 12x12 cylinder of an engine running at 110 r.p.m. Scattered about in various parts of the house, were divers vessels containing cylinder and engine oil, while on the door step was a powder-keg overflowing with a heavy strap oil for use in the journals of the fan shaft.

Waste in Use

The number of drops fed through the lubricator was reduced to 35 per min., and by careful experiments the exact amount required per day was ascertained. The oil for the engine bearings, which had hitherto been fed in a haphazard manner was subjected to similar methods to determine the proper amount needed to oil the bearings adequately, and two oil cans of standard size were placed in the engine room, so that in the future no excuse could be offered for placing oil in open vessels into which particles of dirt would readily fall, seriously impairing its lubricating value. Many gallons had hitherto been wasted in such slovenly methods as were in use. Experiments proved that the large shaft bearings could be lubricated by a low quality of polar grease more economically than by oil, so the use of oil was discontinued. This was ascertained by making careful experiments, which occupied three days, during which time temperature tests of all bearings were taken, with a mechanical engineer's thermometer. In a like manner the proper amount of oil for a safe operation of the entire fan equipment was precisely determined.

A blank similar to Form 1, was made out in triplicate and upon this the clerk in the oil house would enter the amount issued to the fan engineers during the month, and in case the amount was more than the printed figures, a demerit mark was entered, of which I shall have more to say further on.

One of the filled forms was kept at the oil house, one filed at the office for the foreman's and superintendent's use, and one given to the engineer. By this method, all concerned were kept posted and lapses to the careless methods of former days were easily prevented.

M. & M. COAL CO. X. COLLIERY	Aug. 1911

Form 3

Waste by Mixing with Impurities

The next visit was to the motor barn, wherein six 8-ton electric locomotives were housed at night. Right at the entrance was a powder keg filled with sand; and in close proximity, as though keeping company with it, was a battered powder keg containing a high grade of lubricating grease with a fair amount of sand lying on its surface. This had evidently fallen into it while some careless employee was filling the sandbox of the locomotive previous to making the initial morning trip. Investigation disclosed the fact that much expensive lubricating grease was rendered valueless by just such careless methods.

The inspector found that the armature and axle bearing were lubricated with this kind of grease, and it really seemed as if workmen whose duty it was to attend to the bearings, thought that the grease had remarkable penetrating qualities, as he did not stop when he had filled the bearing boxes to the utmost capacity but continued to apply the lubricant, the exterior of the bearings being covered with a liberal amount of the grease. But even with this he did not rest content for he had a habit of making a hole through the center of the boxes and pouring a high-grade of engine oil into the armature bearings, which would promptly run through the lodge in the lower half of the motors to the detriment of the insulation of the field coils.

The practice of filling sand boxes in the locomotive houses was strictly prohibited, so that valuable lubricants would no longer be rendered useless by the addition of sand, and the net saving obtained by correct methods of lubricating the locomotives was really amazing, as all expenditure for high-grade grease was saved. Careful experiments proved that lambs' wool used in all bearings, end journals included, was far superior to any other form of lubricant, when saturated with a small amount of engine oil. The use of a lubricant purchased on the open market for the quieting of pinion and gear wheels was found to be far more efficient and more economical than polar grease. The motor hostlers were also furnished with a blank similar to that marked Form 2. This was distributed in the same manner as the first form.

Waste of Oil by Excess Feed

The next leak the inspector discovered was in the power plant, where there were in operation four 250 kw. engines operating at a speed of 220 r.p.m. One of the engines was equipped with ordinary sight feed, hand-filled oil cups; one of the others, with an automatic oil-cup system, through which the oil was forced by a small rotary pump, which was attached to the engine; the remaining two had the inclosed splash type self-oiling systems. The engineer furnished the surprising information that the engine equipped with the hand-filled oil cups, consumed the least amount of oil, although the other engines had been purchased, partly because of the saving in oil that the manufacturers insisted would be

effected in the operation of their engines. Further investigations developed the fact that the reason why the hand-filled oil cups consumed less oil, was that the engineers had regulated the handfeed so that their periods of rest would recur at regular intervals, while the oil in the inclosed type of engine was changed when the whim of the engineer dictated without regard to the condition of the oil, which nevertheless was promptly thrown into the sewer as being unfit for further use.

Reclaiming Waste Oil

A new method of changing oil was inaugurated, determined by the number of hours the engines had operated, and the

Form 5

dirty oil was placed in 5 gal. tanks equipped with sight-feed glasses and small taps, placed about 1 in. from the bottom. In about 10 or 12 days the impurities in the oil would settle to the bottom, leaving it clear. Then it was drawn off and delivered to other places as I shall show later. Fig. 3 is the form that was issued for the use of the power-house engineer.

On the way over to the breaker the inspector's shoes stuck in a mass of oil and dirt. A careless employee, whose duty it was to oil the mine-car wheels, had more concern, as a moment's observation disclosed, in oiling the exterior of the car wheels than their axles. The oil would promptly run off and soak into the ground with the result that much oil which had been purchased for lubrication merely saturated a path along the car tracks.

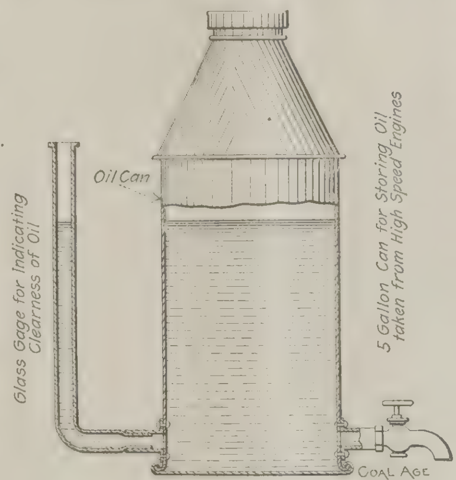
This employee was promptly furnished with a form to fill out and further waste was effectively prevented. As he was also furnished with a stencil to mark the date of oiling, his foreman could readily see whether all cars were oiled in due proportion to their needs.

Using Oil a Second Time

In the breaker were found the most lax methods of oiling and safeguarding bearings. A large number of the oil boxes contained no waste whatever, and the oiler would pour in oil, only to see it promptly run out at the bottom. As there were over 200 bearings the waste was really enormous, so a blank similar to the other was ruled and efforts made to prevent future loss. The oil saved in the power plant was now delivered to the breaker, as it was found to be equal in quality to the grade there used. Thus another item was deducted from the oil bill.

Waste of Oil in Hot and Cold Weather

At the close of the tour the inspector paid a visit to the oil house. Here he found several barrels of oil upon the



Cleansing Tank for Waste Oil

racks, where it was served to the employees, who had been in the habit of bringing all sizes of oil cans and demanding whatever amount of oil they thought necessary for their needs, and he found that a month's supply of oil was shipped from the general storehouse on the first of every month. Through the lack of room, some of the barrels remained outside until required, with the result that in the summer months, much oil was lost by evaporation. In fact, in the month of August, one entire barrel of gasoline was lost in that manner, while in the winter, much of the heavy oil was lost owing to its adhering to the interior of the barrel.

A large saving was effected by installing metal tanks, which were amply large for an entire month's supply. They were equipped with automatic measures, so that only the exact amount of oil required, would be drawn and delivered directly into the oil cans, and all guesswork was thus forever eliminated.

The Merit System

A merit system for the recognition of those men who were really interested in saving money for their employers was instituted. Form 5 was made up at the office and posted at a conspicuous place, so that all could see the standing of the various engineers, and a friendly talk was delivered to all users of oil, the speaker emphasizing the money value of the wasted oil and asking each workman to use lubricants in the same careful way in which he would use any commodity which he had to purchase out of his own pocket.

After the new system of distributing and using oil had been in operation long enough to prove its effectiveness, the bill was found to have been reduced 37½%.

Coke Notes

The coke from the lower Connellsville field is smaller than that made from the Connellsville coal in the old region, and up to about a year ago it was thought that large, bulky coke could not be made from lower Connellsville coal without pulverizing or washing. A test was recently made at one of the older plants in the old region in small ovens with coal from a lower Connellsville mine, and the coke made was of good structure, equal to the old-region coke. Whether this reversal of form was due to the small 11-ft. oven or to the peculiar character of the coal from that particular mine, is not known, but the fact remains that at the old plant large coke was made with the lower Connellsville coal.

The Mitchell oven is a modification of the Belgian type, one difference being that it provides an improved combustion chamber. The process is identical with that of the beehive oven. In this type, there is an opening at both ends; consequently, the oven can be discharged in a few minutes by a pusher extending through the oven, thus utilizing practically all the heat for the next charge. The oven is immediately charged after pushing. The dimensions are approximately as follows: Height at the center, 7 ft. 6 in.; height at end, about 4 ft.; width at pusher end, 4 ft. 10 in.; width at discharge end, 5 ft., and length, 32 feet.

While giving testimony before the Senate Committee on Interstate Commerce, Judge E. H. Gary is credited with the following remark on Illinois coke:

> If some concern like the United States Steel Corporation, which could afford to expend the necessary sums of money to make these experiments and tests had not been in existence, the country would not know today that coal mined in southern Illinois can be used for coking purposes. The steel corporation is now using 25 per cent. of southern Illinois coal in its furnaces and later on we will increase the amount to 50 per cent. As a result of our experiments with this coal we have purchased thousands of acres of it in Illinois at $30, which if located in the Connellsville, Penn.,' field would sell for $1000 per acre.

The Problem of Mine Timbering

By R. B. Woodworth*

With the growing necessity for intensive mining and the depletion of our forests, the problem of mine timbering has come prominently forward as a most important factor in the cost of coal. Four methods of dealing with the problem are discussed in this article which is the first of a series on mine timbering having special relation to the use of steel.

Success in the conduct of mining operations is only attained when the product of the mines is marketed at such rates over and above the cost of production as will insure a fair return on the capital invested. Other considerations may be brought prominently into view during periods of exploitation or at times of depression, but in the regular run of affairs, the men who operate mines do so in order to reap the rewards of their labor. To reach this desired end in the highest measure it is required that the capital invested be as small as the fundamental principles of true economy will permit, that the cost of production be as low as intelligent skill can make it, and that the rates at which the product is sold be as high as the most efficient sales organization can secure. Under modern conditions of competition this high success in the conduct of mining operations is gained by that careful attention to details which is known as scientific management.

Where the Operator Must Look for His Profit

Time was, when many features of mining could be left to unskilled workmen; today in order to insure the largest possible return on capital investment, every problem which has to do with the employment of men and expenditure of money demands serious consideration and requires solution, not by rule of thumb methods, but by the application of the rules of economic science. The timbering of the mines is one of these problems, and it is to the credit of many mine owners and operators that they have appreciated its importance and applied their intelligence to its solution.

The price paid by the consumer per unit of product is in a measure fixed by economic law and is, therefore, in a way beyond the control of the mine owner or operator. He may decide against selling in any particular market; but once he decides to sell, the price is fixed for him by the conditions of competition in that market. So far as the operator is concerned the price that he receives may be regarded as made up of four items: cost of production in the mine, cost of preparation at the mine, cost of transportation from the mine and profit or loss. The third of these items he does not control, and the magnitude of the fourth is, therefore, dependent upon the measure of success with which he deals with the first two. The smaller he can make these, the larger will be the fourth.

It is not intended, in this article, to deal with the cost of preparation, but it is purposed to point out that the cost of production in the mines is under the control of the operator and that it behooves him to pay careful attention to all the elements which enter into it. These elements are: (1) Cost of labor and tools. (2) Cost of explosives. (3) Cost of transportation and hoisting. (4) Cost of mine timbering. (5) Cost of superintendence and administration. While the cost of labor per man has increased in recent years and may continue to do so, scientific management reduces the cost per ton by the introduction of machine methods of mining. Such management also reduces the cost of explosives by the selection of the most economical forms and the regulation of their use and also by the substitution of hydraulic blasting. The cost of transportation is reduced through the displacement of mules by locomotives, wooden cars by steel cars, and poor roadways by good ones. The cost of superintendence is lowered by the employment of trained men having skill and intelligence rather than brawn, and the cost of mine timbering is reduced by that intelligent and discriminating use of the materials of construction which lies back of the structural phase of our industrial development.

Importance of the Mine Timber Problem

Once the subject of mine timbering was no problem. The mine foreman sent his timbermen into the adjoining forest to cut down what few props were needed for use at the mine entrance and in the rooms and headings and recked not what particular size of timber he used or whether, in using for mining purposes the best timber which grew on the land, he was not at the same time committing an economic crime. The mine owner who now looks back over the records of the past will note that the best timber has long since disappeared, that any kind of timber suitable for mine-timbering purposes is in some localities hard to get, and that year by year the cost per ton for the maintenance of the timbering in shafts and headings has steadily grown. True, this growth is not entirely due to the depletion of the forests but in part also to the deeper character of the workings, the larger sizes of timber required in such deeper workings and the increased lengths of headings that it is necessary to maintain.

Wood in the Mines

Wood has played a most important part in the timbering of mine excavations. In 1905, according to statistics gathered by the U. S. Department of Agriculture, 171,624,000 cu.ft. of wood were used in underground mining operations in the United States. This required, at a conservative estimate, the deforestation of 410,000 acres of land, an area more than half that of the state of Rhode Island. In the bituminous-coal fields, the cost for timber alone amounted in that year to 2.3c. per gross ton of coal mined, and in the anthracite-coal fields to 7.7c. The year 1905 was one of comparatively cheap timber, and while no statistics have been compiled since that time, the probabilities are that today with wood at a higher cost per cu.ft., and with larger sizes in use, the cost of mine timbering in wood is about 4c. per gross ton in the bituminous-coal fields as a whole, about 6c. per gross ton in the bituminous-coal regions of Pennsylvania, and about 9c. per gross ton in the anthracite-coal fields.

The cost of wooden mine timbering is not a permanent investment. The life of the timber is so short and the depreciation due to decay and breakage so great that the expense must be charged to maintenance, renewals and replacements and not to capital account. In consequence it must be considered as a fixed charge applicable to each ton of coal mined and increasing in amount for any particular mine as the working faces get farther away from the opening. The more extensively coal is mined, the greater becomes the timbering cost per ton even if the unit cost per cubic foot of timber does not increase. This would not be the case if a material were in use that possessed great durability and was subject to renewal only after long years of service or not at all during the life of the mine. In this case the timbering cost should rightly be charged to capital account with allowance for depreciation.

Satisfactory in great measure as the use of wood has been and will yet be,

*Engineer with the Carnegie Steel Co., Pittsburg, Penn.

Note—Paper read before the Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.

these facts show the importance of the problem of mine timbering; and if a change in method can be made that will keep the cost from growing or even diminish the increase, a study of the matter will amply repay the operator. The use of steel in the mines of Warwickshire has cut the timbering cost 2c. per ton, a reduction not to be despised, but more of that later.

The importance of the mine-timbering problem is to be seen further, in the expedients which have been devised to prevent the increase in cost due to use of wood. These expedients are:

1. Methods of mining which either do not require the use of timbering at all or require a minimum amount—Mining without timbers.

2. Methods of reducing cost of wooden mine timbering by prevention of increase in price—Reforestation.

3. Methods of reducing cost of wooden mine timbering by increasing its life—Preservative treatment.

4. Methods of reducing ultimate cost of mine timbering by substitution of other materials for wood—Substitution.

Each of these expedients has its place. Indeed, modern economics require that each of them be given consideration and that no method be used in a place for which it is not in every way the best fitted.

Mining without Timbering

In iron mines operated on the caving system, where the timber is broken and crushed by the fall of the ore or even broken up by dynamite in order to secure the proper subsidence of the roof, top slicing and subslicing have been resorted to in order to get out the ore with more cleanliness and at less expense. In the case of coal, however, these methods would be applicable only to very thick seams and would be objectionable by reason of the fineness to which the product would be broken.

The filling of underground excavations by culm flushing was first tried out in 1891 by Mr. John C. Haddock at the Dodson Colliery of the Plymouth Coal Co.; and the use of culm, clay, sand, etc., for this purpose has come into extended use both at home and abroad under local conditions where the subsidence of the superincumbent strata means a damage and probable property loss which cannot be disregarded.

There are also intimations that the room and pillar system of mining will some day be displaced by the use of the long-wall system, which in the United States has had its most extensive development in Illinois and which has been prosecuted with much success, abroad. The long-wall system of mining, while it does not do away with timbering entirely, makes possible its more economical use by the removal and replacement of the mine-timber sets and, therefore, offers a field for the use of substitutes for wood that are better adapted to frequent removal and replacement.

Reforestation

The chief merits of wood as a material for mine timbers have been its wide distribution and ease of access from the place of use, its consequent cheapness and the simplicity with which it can be framed for use. Its cheapness vanishes when the mines become dependent on far-distant sources of supply. And so the mining companies do well to provide for the future, by taking steps to renew their timber supply and thus make themselves independent both as to the supply and as to its cost. Where, however, the companies do not own the surface land under which they mine, or in case this land is worth more for agriculture than as a forest, the matter is not so simple.

There is also this other consideration: a wise conservation of our timber resources means the reservation of the best timber for the more delicate and particular purposes of the arts and industries. With the gradual exhaustion of the hardwoods and the species of soft woods peculiarly adapted to architectural uses and to the manufacture of furniture, etc., the cutting of such timber for baser uses may be sheer economic waste. The coal mines, as a rule, are in the hardwood sections of our primeval forests, and their reforested lands, will grow the most valuable species of timber.

Preservative Treatment

The unbiased student of underground mine-timbering conditions is struck at

Steel Timbering at Maxwell Colliery, Lehigh & Wilkes-Barre Coal Co.

once by the economic waste involved in the use of wooden timbers in situations where the loading or temperature conditions are such that the wood cannot be expected to last for more than a limited period of time. The two most serious elements of this waste are decay and destruction by insect action. While there is some waste due to the lack of proper proportion between the sizes of the legs and collars in the three-piece gangway set of timbers as ordinarily framed, and while 10 per cent. of all the lumber going into underground operations is wasted in framing and fitting, another 10 per cent. of it is destroyed by insect action and 45 per cent. just simply rots. Insect action may, to a large extent, be eradicated by peeling the timber before it is placed in the mines, but the removal of the bark does not prevent decay, for wherever moisture and heat coexist within the mines, the bacterial agencies of decay, the spores of which are everywhere present in the atmosphere, begin their destructive work.

Proper preservative treatment may reduce disease and decay in mine timbers to a minimum, but it is probably impossible to exterminate the disease and wholly prevent the decay. There seem to be four valid objections to preservative treatment as a final solution of the underground-timber problem:

1. According to the best information at hand, properly treated timber will cost, f.o.b. cars at the mines, two and one-half to three times the cost of timber not treated, and at that will not last half as long as substitutes that can be purchased for less money.

2. If treated at the mines, the time necessary for seasoning the wood before it is ready for treatment and the interest charges on its value during the time of seasoning and treatment involve delay and expense.

3. Much of the timber cannot economically be treated, as it is not economy to apply preservative treatment to material liable to destruction under service conditions by crushing and not by decay.

4. In spite of many years of experimentation, preservative treatment is attended by many difficulties and large uncertainties. The best woods do not take kindly to treatment. It is best adapted to, and most successful with, open porous-grained woods which are of low value from a structural standpoint.

Substitution of Other Materials

Substitution of other materials in place of wood is the solution of a problem in above-ground structures similar to the problem of mine timbering, and there is no valid reason why this solution will not also apply to underground structures. True, wood has not been and will never be entirely displaced above ground; neither will it be below ground. No one material has taken its place above ground; neither will any one material take its place under ground; but it may be predicted that for each condition of mine timbering, that material of construction will eventually be used which experience and accurate study of the economic laws of design indicate to be most suitable, and as a general proposition this material will be steel, since of all other materials it is most like wood in its physical qualities.

The conclusion is reached, therefore, that for the near future at least, the use of timbering within mines will be continued, particularly within the coal mines, and that probably those methods of supporting excavations will never entirely be displaced, which by their simplicity have proved heretofore the most economical and, therefore, the best.

(To be Continued)

Steel Timbers for Roadway and Pump Room, Honey Brook Colliery, Audenried, Penn.

Turbine Driven Feed Pump

The Victor-American Fuel Company is building at Hastings, Colo., and Gallup, N. M., two thoroughly uptodate alternating-current central-station plants for furnishing power to its mines in these two districts. The first installation consists, at each plant, of one 500-kva. Curtis turbo-generator unit, this to be supplemented by a 1000-kva. unit.

One of the novel features of the installation is the use of steam-turbine driven boiler-feed pumps. These are of the Kerr-Alberger three-stage centrifugal type, of 70 gal per min. capacity against 170 lb. pressure. While more costly than others, these pumps are expected to prove economical by reason of their greater efficiency, and saving of repairs.

European Wash House Practice

This is the third and concluding article on the subject. Careful analysis of costs, both of installation and maintenance, are given, together with plan of a typical English plant.

It has been shown that a large number of the bathing equipments at Belgian collieries have been installed in the Liége district. Owing to their undoubted success, the movement has spread into other districts, such as the Central and Charleroi, where Messrs. Goehmann & Co., of Brussels, who specialize in this type of plant, have laid down a number of important installations.

The total average number of workmen employed in the 43 Belgian pits which have adopted washing installations is 21,560, of which 16,650, or a ratio of 77.3 per cent. regularly avail themselves of the shower-bath equipments. Of the remaining quarter or so of the workers who are irregular in the use of the equipments, or obstinately stand aloof, the majority of these exceptions are due to particular circumstances, such as, for example, their dwellings being close to the pits.

The figures, therefore, indicate that the working class is quite willing to make use of the sanitary accommodations placed at their disposal. The total cost of the 43 installations mentioned has amounted to $358,200. The average outlay per month for working them is $3600, and the average price of one bath is about one cent, excluding interest on capital. In these figures no account is taken of certain smaller installations erected exclusively for the inspecting or managing staff; they refer solely to the equipments for the workmen.

Miscellaneous Notes

Table 1, herewith, kindly placed at our disposal by Mr. Richard Jacobson, who has interested himself greatly in this question, gives some statistics regarding several prominent Belgian mines. It will be seen that in the poorest case, 50 per cent. of the workers make use of the baths, while in more than one instance the whole of the staff use the accommodation provided.

The cost per bath ranges from ½c. to slightly over 1c. In two cases the bathing accommodation is so much appreciated by the workers that they contribute a small amount periodically in order to assist the working expenses. In some of the collieries, canteens are provided near the bath houses, supplying hot coffee, a point of material assistance in preserving the health of the miners who have to go some distance to their homes.

Compulsory legislation on this matter in Belgium only came into force quite recently, yet for some time previous certain mine owners had found themselves compelled to install baths and dressing accommodation in order to prevent their workmen from leaving their pits in favor of those where these advantages were provided.

In some areas the question of water supply is rather a serious one, and where there is this difficulty, means are used to purify the water which has been used by the miners in order to return it to the tanks for reuse. This practice has proved most successful and, in the circumstances, economical.

Shower Baths

From the point of view of time economy, the shower bath enables a man with a minimum consumption of water (7 to 8 gal. per bath) to have a complete wash in a short time, generally ten minutes. The water is supplied at a temperature of 95 to 100 deg. F., and is immediately drained into the underground pipes. This form of washing is complete and quick, as compared with the ordinary bath system, when the cell is constantly engaged at short intervals by a number of men.

The pavement of the bath rooms and dressing rooms is of cement, asphalt, or ceramic tiles, and the cleaning of the same is effected by means of a hose. The principle which prevails in Belgium is to allow each man to have a separate

*Abstract of paper appearing in the Iron and Coal Trades Review, London, England.

†This inc udes three separate buildings: One for men, 1 for women, 1 for superintendents, with laundries and accommodation for meals.

cell with one or two compartments; the partitions are of plain or corrugated sheet iron, porcelain, marble, or thick glass. In general the workman only dresses partially in the cell and finishes up outside on benches fitted against the lockers and clothes hoists.

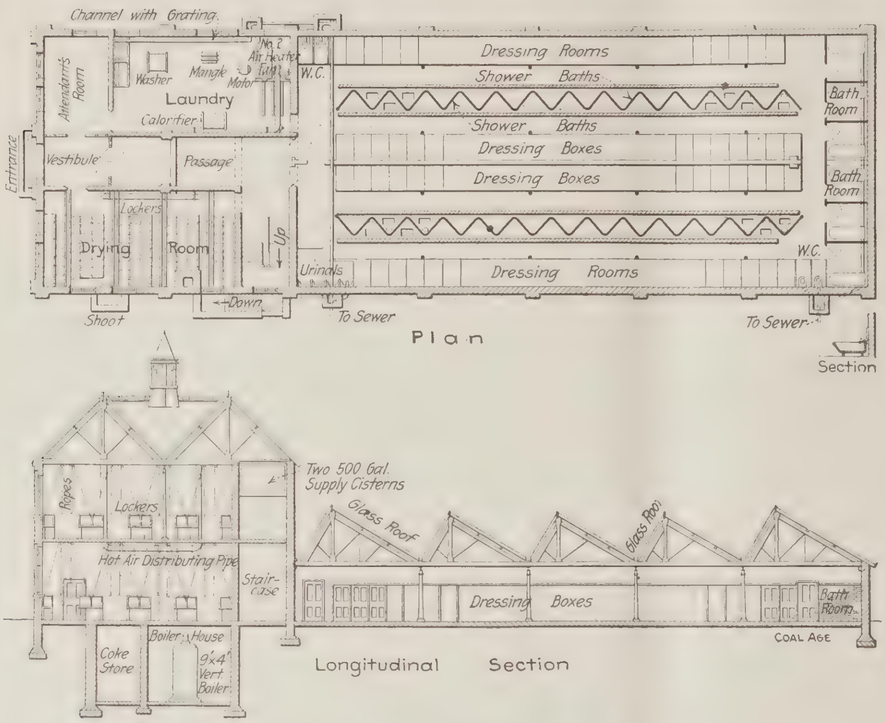
The protection, drying and ventilation of the clothes are done in two different ways: (1) In metallic lockers well ventilated for this purpose, and constructed of expanded or perforated metal; (2) on hanging apparatus provided with hooks, and working by means of pulleys, by which they are hoisted to the ceiling[1]. On the basis of Belgian experience, Mr. Jacobson has made an estimate of the cost of a shower bath, lavatory and dressing-room installation for 100 men in an industrial establishment, such as a patent-fuel works. This is shown in Table 2.

Brunner, Mond & Co.'s Installation

Up to the present the subject of industrial bath establishments has not made much progress in England, although the question is now being investigated.

Probably, however, the most complete and important British installation of this nature which has yet been made is that designed and constructed by the Leeds Fireclay Co., Ltd., of Wortley, Leeds, for the works at Winnington of Messrs. Brunner, Mond & Co., Ltd. The general arrangement of this scheme, including baths, dressing rooms, drying rooms and laundry, is shown in the accompanying drawing, and numerous differences in arrangement will be noticed as compared with the Belgian designs.

The zig-zag cubicle was designed with a view of saving not only space but a considerable expense in the length of the building. The widest part of the cubicle is 6 ft., and as 4 ft. clear is really necessary to allow an adult to scrub himself down freely, it will be seen that this innovation has effected a most important saving in space, and, moreover, there is no wall surface lost.



Miners' Baths at the Winnington Mines

The footbaths are made in fireclay, and sunk flush with the floor, the wastes discharging into an open channel covered with a galvanized-iron grating. The seat in the angle is also made in fireclay, and the floor falls all round toward the footbath, the floors in the dressing cubicles then falling toward the channel, so that the whole place can be cleaned out with a hose. The user has full control of the shower, by means of a patent valve by which the cold water must be turned on before the hot, so as to reduce the possibility of scalding as far as possible. The hot- and cold-water service runs round the cubicles, and is utilized to hang the waterproof curtains.

The dressing boxes are constructed in wood with the partitions standing well clear of the floor so that a hose can be used with freedom. At the end of the building there are six slipper baths with large outlets and quick-filling valves. The partitions in these baths are constructed in "Shepwood" brick, supported clear of the floor with girders.

The whole building is heated with steam pipes in the winter months. Sanitary accommodation is also provided in the way of four closets and four urinals. Fixed throughout the building there are also hose taps so that the place can be easily washed down, and the ventilation is arranged to rapidly get rid of steam.

General Details

The hot and cold services to the baths are supplied from a storage in the roof, and through a large heater situated in the laundry. In connection with the latter there is also a large hot-water storage, such that the maximum demand can be met continuously for some hours. The laundry is equipped with a washing machine, tubs, a set of drying horses, mangle, etc., so that the washing of towels can be accomplished with the minimum of labor. The steam for this and the heating of the building generally is furnished from a vertical boiler.

There are two drying rooms, one on the ground floor and one on the upper floor; they contain 200 cupboards supported clear of the floor, each numbered and furnished with a key. Above each cupboard there are provided quadruple hooks, the rope of which works through a pulley secured to the ceiling. The end of the rope passes through the top of the cupboard and is secured to the interior by a hook so that the clothes cannot be lowered by anyone not in possession of the cupboard key. By a suitable fan driving hot air into and across the rooms, wet clothes can be dried in an hour or two. As regards operating cost, it has been found in practice that one man is sufficient to work the whole place.

TABLE 2. ESTIMATED COST OF A SHOWER BATH, LAVATORY, AND DRESSING-ROOM INSTALLATION FOR 100 MEN FOR PATENT-FUEL WORKS

A—Installation with the Most Needed Requisites		B—Installation More Luxuriously Furnished	
Heating	$296	Heating	$296
Hot-water supply and shower baths	365	Hot-water supply and shower baths	365
Lavatory basins and wash-stands	178	Lavatory basins and wash-stands	178

[1]A recent law enacted has made the use of these hoists prohibitive because of the danger due to articles falling from the pockets of the clothes.—Editor.

United Mine Workers' Convention

After adopting a policy to be followed out in negotiating a wage-scale agreement, and after selecting Indianapolis as the place for holding the next convention in 1914, the United Mine Workers of America adjourned their convention at noon, Feb. 2.

The committee on policy reported that the method of negotiating wage contracts that has been followed for some years past, has proved entirely too expensive because of the fact that large delegations have been kept waiting for days and sometimes weeks for the scale committee to report. It was recommended that authority be given to the miners' scale committee to negotiate an agreement, with the understanding, however, that the proposed contract be submitted to a referendum vote of the union membership, or to a reconvened convention, and this action was accordingly taken.

One of the most important accomplishments of the convention was the adoption of a constitutional provision for holding their conventions and elections of national officers biennially. Edwin Perry, secretary-treasurer of the organization, has compiled figures showing the cost of the present international convention to be $180,000.

Joint Scale Conference Adjourns

The joint-scale committee reported that the demands of the miners and operators were so diametrically opposed that there was no chance of reaching an agreement at this time, and adjourned indefinitely on Feb. 1. A committee composed of President White for the miners, and an operator and a miner from each of the four states represented in the conference, was appointed to entertain any proposition that might be submitted by either side and empowered to call the conference to reassemble if an agreement seemed possible.

There was little or no talk of a strike to be called after Apr. 1 in case an agreement has not been reached before that time, and it was admitted by the miners that the organization was not in condition financially to carry on a long strike.

The operators, in the joint conference, took a most decided stand against the introduction of the unlimited "check-off" system demanded by the miners. This would require the employers to deduct from a miner's wages any sum that the organization might demand that he pay to the treasurer of the local union. The operators expressed themselves as willing to check off the regular dues of the miners, but refused to have anything to do with any other assessments levied by the organization. The continuance of the scale committee with implied orders to keep up negotiations is construed to mean that there may be a compromise.

Coal Law Needs Amending

The present coal-land law has one serious defect, which should be remedied if a leasing law is not enacted. The restriction of area that may legally be acquired to a maximum of 160 acres for an individual and 640 acres for an association is not in accord with good mining practice. The fixed charges on the cost of a modern coal mine, provided with the uptodate equipment necessary to conserve life and property and to assure maximum recovery, are too high to be assessed against the output of so small a tract, especially if the coal seam is of only moderate thickness. A law designed to promote the practical utilization of coal deposits, whether the system contemplates sale or lease, must provide for the holding of a large enough unit to permit the opening and equipment of a modern mine and to warrant its economical operation. Without such provision for commercial operation too great an advantage is given to the land-grant railroads and large coal companies already in possession of considerable areas of high-grade coal (From 32d Annual Report, Director United States Geological Survey.)

Alabama Examinations for Mine Foremen and Firebosses

The Alabama state examinations for first- and second-class mine foremen and fire bosses were held in Birmingham, Jan. 22 to 26 inclusive. C. H. Nesbit, chief mine inspector, has made public the list of applicants who have been successful in passing the examinations. The highest percentage, 89.5, was averaged by G. L. Cunningham of Dolomite; the second highest, 89, by H. G. Hubbard and T. H. Black, both of Maben, while the third highest, 88, was credited to M. F. Bell, of Blocton. All of these filed applications for the certificate of first-class mine foreman.

The following will be awarded certificates by the board of examiners and will be exempt from further examination in their respective classes:

First Class Mine Foremen—John Reynolds, Dolomite; G. L. Cunningham, Dolomite; Will Smith, Bell Sumter; Will Herring, Bell Sumter; J. O. Seigler, Margaret; J. M. Ware, Dolomite; J. B. Hunter, Altoona; S. B. Kennedy, Johns; G. L. Nesbitt, North Birmingham; T. H. Black Maben; H. H. Hubbard, Maben; G. W. Caviness, Cordova; H. C. Wood, Blocton; J. H. Lawrence, West Blocton; John Kuffner, Blocton; John Fullman, Coleanor; M. F. Bell, Blocton; J. H. Gardner, Samoset; James Kirkpatrick, Wylam; M. D. Drennen, Palos; J. L. Bryson, Margaret; C. C. Custered, Margaret.

Second Class Mine Foremen—Opie Gamble, Delmar; John Oliver, Natural Bridge; W. L. Smith, Altoona; W. R. Gibbs, Warrior; W. W. Earnest, Coal Valley; L. F. Taylor, Altoona.

Fire Bosses—Thomas Gilmore, Pratt City; Will Chatman, Blossburg; Mathew Howard, Adamsville; Gus Burkhart, Adamsville; C. G. Ellison, Bell Sumter; M. M. Barron, Dora; William Ellis, Wylam; W. D. Millstead, Dolomite; J. D. Dunlap, Margaret; Tom Ellis, Wylam; R. L. Hutton, Glen Carbon; William W. Lewis, Dolomite; James Stewart, Cardiff; Robert Hartley, Piper; J. A. Ivie, Coleanor; Marvin Henderson, Mulga; Richard Hopkins, Johns; J. M. Robinson, Blossburg; C. B. Jones, Margaret; George Smith, Abernant; J. J. Burnett, Dora; John Waine, J. W. Adams, Robert Lewis, J. A. Hartley, J. M. Townley, F. Tune and W. B. Brown.

Fuse and Squibs

Knowing that mining accidents often result from trivial causes other than the actual use of explosives themselves, the U. S. Bureau of Mines has just completed investigations of fuse and miners' squibs and the rate of burning of the former as influenced by temperature and pressure. The results are contained in Technical Paper No. 7, "Investigations of Fuse and Miners' Squibs," by Clarence Hall and Spencer P. Howell, and Technical Paper No. 6, "The Rate of Burning of Fuse," by Walter O. Snelling and Willard C. Cope.

The technical paper on investigations of fuse and miners' squibs, by Clarence Hall is one of a series of publications published for the use of miners, tunnelers and quarrymen and its purpose is to enable those in charge of blasting work to select the best devices for igniting explosives, thus aiding in the reduction of accidents.

The author says: "The rates of burning of the various kinds of fuse sold in this country vary from 18 to 40 sec. per ft. in open air. However, the miner or shotfirer seldom knows the rapidity with which different kinds of fuse will burn. It is true that some fuse is marked slow or fast and is even distinguished by the color of the paper wrapper, but this is not always the case. Without such information a miner who is accustomed to a certain brand of fuse may use another that burns faster with the result that a charge may explode prematurely and menace all connected with the work. However, it is believed that the rate approved by the Bureau of Mines—namely, 90 sec. per yd.—will meet the various mining conditions in this country.

Careful tests should be made of the rate of burning of fuse whenever there is any doubt as to its soundness. The manufacturers may produce a fuse with a regular rate of burning, but the rate may be changed by bad handling—for instance, by squeezing it so as to disturb the powder train, or by suddenly and roughly opening the coil when it is stiff from cold so as to crack it—or it may be bruised by rubbing against the rough surface of rock."

"Fuse should be carefully handled and never laid in a damp place before using. In cutting and fitting it into place, care must be taken that the powder core does not run out of the fuse, for that might cause a misfire. The fuse should be cut straight across with a sharp knife, just before placing the end in the detonator and in a humid atmosphere at least 1 in. should be removed to insure unfailing detonation. The fuse should be fitted gently into the detonator which should then be crimped on the fuse by a suitable crimper."

The conclusions reached in the investigations into the rate of burning fuse, Technical Paper No. 6, show that it is important for time fuse to have a uniform rate of burning, and in almost all blasting operations the fuse which is used is assumed to burn in a regular and uniform manner.

When fuse has been subjected to such conditions as produce acceleration or retardation in its rate of burning it becomes dangerous. Rapidity in burning increases the liability that the shot will explode before the miner has left the face; slow burning increases the possibility that the flame in the fuse will progress so slowly that the miner may be injured by a delayed shot when he returns to the working face. Any marked change in the rate of burning of time fuse is dangerous, and from a study of the list of accidents in mines and quarries each year, it would seem that injury and loss of life are often brought about by such changes.

Under ordinary conditions nearly all types of fuse show great uniformity in their rate of burning. Practically all kinds of fuse examined in connection with the preparation of this report had a total variation in their burning under normal conditions of less than 20 per cent. and all would have been passed under the requirement stipulating "no variation greater than 10 per cent. above or 10 per cent. below the average rate of burning."

Climatic conditions affect to a considerable extent the rate of burning of the less waterproof types of time fuse. Damp fuse burns more slowly than normal fuse, and fuse that has been wet and then thoroughly dried tends to burn at a rather slow rate, and may even cause delayed shots by smoldering for a considerable time. Fuses containing several wrappings of tape saturated with tar or asphalt resist moisture to a considerable extent, and may be used for firing shots under water, provided the fuse is not allowed to remain too long a time in contact with water before the shot is fired.

Copies of the technical papers may be obtained by applying to the Director of the Bureau of Mines, Washington, D. C.

Program of the Bureau of Mines

The report of the Secretary of the Interior recommends the addition of two or three more mine-safety cars to the present equipment of the Bureau of Mines. Cars are now stationed at Billings, Mont., Trinidad, Colo., Evansville, Ind., Huntingdon, W. Va., Pittsburg, Penn., and Wilkes-Barre, Penn. Besides these six cars is one dividing its time between Rock Springs, Wyo., and Salt Lake City, Utah. The six mine-rescue stations are at Pittsburg, Penn., Knoxville, Tenn., Birmingham, Ala., McAlester, Okla., Urbana, Ill., and Seattle, Wash.

The secretary urges that the Bureau of Mines be empowered to collect and publish statistical data, and in a concluding paragraph declares that "the buildings and grounds at Pittsburg now occupied by the Bureau of Mines, for its investigations, are inadequate for its needs, unsuited to its purposes, and are held subject to the wishes and needs of another department of the government.

Western Hospitality

Western hospitality is not limited by its surroundings. The accompanying photograph shows the first boarding house of the International Coal Co., of Montana. In spite of its rough appearance, it was very clean and comfortable inside, and the meals served would have done justice to any first-class café. It is needless to say that this has now been replaced by a larger and better-looking structure.

TYPE OF BOARDING HOUSE FREQUENTLY MET IN WESTERN CAMPS

British Coal in Spain

The British consul, in a report on the trade of the consular districts of Bilbas for the year 1910, says the consumption of coal in Bilbas and neighborhood during the year amounted to 778,312 metric tons, made up of 465,135 tons from the United Kingdom and 313,177 tons from Spanish mines. Covering a period of three years the consumption of coal in this district is shown in metric tons in the table herewith, including the country of origin:

	1908	1909	1910
United Kingdom...	459,360	460,761	465,135
Germany	......	411	......
Spain	291,698	268,623	313,177
Total	751,058	729,795	778,312

In this market, as will be observed, British coal more than maintained its position, chiefly due to increased imports of North Country "smalls" for coking by the iron and steel works. In recent years there has been a tendency to consume smaller quantities of Spanish fuel, but last year's figures show a notable change, resulting in an increase of 44,554 tons, as compared with 1909. This also is largely attributed to greater consumption in the local coking ovens. The patent-fuel works, recently erected at Luchana, also consume Asturian "smalls," so accounting for a portion of the increase. The British coal is chiefly imported from Newcastle and Newport. There does not appear to be a wide margin in the quoted price per ton, as in June, 1911, the quotations were: Newcastle large, $5.71; small, $4.06; Newport large, $5.99; small, $4.58; Spanish large, $5.55; small, $3.78.

From San Sebastian the vice-consul reports that last year 26,666 tons of British coal were imported and 85,070 tons of national coal from the Asturian mines. He notes with regret that the quantity of British coal delivered at this port compares so unfavorably with that of national coal. Although the former is of much superior quality and practically of equal price with the latter, the manufacturers for the most part give the preference to the Spanish coal, the probable reasons being: (1) The coal is delivered in handy quantities; (2) it is quick burning, thus giving less work to the fireman; (3) patriotic motives.

What's in a Name?

By R. W. Raymond*

When our institute was organized, the rules of the North of England Institute of Mining Engineers were adopted for temporary use, and its name was copied without debate. The rules were soon after rewritten to suit the conditions of our society; but the name remained unchanged. The North of England Institute was, in fact as in title, made up of mining engineers—mostly colliery managers—whereas the American Institute included from the beginning the representatives of metallurgy, chemistry, mechanical engineering, geology—in fact, all the arts and sciences auxiliary to mining.

That no change of name was made in the early years was due, I think, largely to the feeling that it was better to let the term mining engineers cover the whole field than to create a long and cumbrous title by attempting to state in it all the branches represented in our membership and proceedings. It was deemed unnecessary to make a complete table of contents out of a title page.

After a few years, there was another reason for conservatism in this respect, namely: the members of the institute became fond of its name, and listened with impatience to any proposal of amendment. It was, at the worst, they said, a lucky misnomer, under which the institute had prospered, and the wide range of activities covered by it was well understood throughout the world. Moreover, although an institute, strictly speaking, was not a body of men, yet this institute "of mining engineers" was just that; and the fellowship of its human members was as important and as dear as the information contained in its volumes. Finally, a good many of us remembered from our school days the old maxim that when a debating society of boys began to tinker its constitution and change its name, it was pretty sure to be moribund; and we had seen the same phenomenon in struggling periodicals, and even in the history of nations.

Having been asked from many quarters to express my opinion concerning the present proposal to change the name of the institute, I must say frankly that I have no strong opinion one way or the other, apart from the consideration of sentiment and habit, which would have weight only with the old members who, like myself, are soon to pass from activity. When the institute was organized, I do not think I would have objected to any respectable designation; but having loved it long under the name by which it happened to be baptized, I might naturally find difficulty in transferring my affections to another. And I confess that the substitution of impersonal abstractions, like "Mining and Metallurgy," for a term of personality, like "Mining Engineers," seems to me somewhat chilly, and to put us somewhat out of touch with our sister national societies of civil, mechanical and electrical engineers.

Yet the proposed title is perhaps better English than the old one; and if it will give deeper satisfaction, arouse more enthusiasm, command wider support and lead to better work, by all means let the new label be pasted over the one that has been with us round the world. It is really a small matter, unless it be made a large one by over-estimating its importance. And my advice to everybody is, to vote with the majority! Only, do not stop satisfied with a mere pedantic improvement, but go ahead with all your might to make the married as glorious as the maiden name!

The disinterested character of my advice may be inferred from the circumstance that my election as honorary member of the institute deprives me of the right to vote, and therefore I must preserve the dignified attitude of a veteran observer only.

*Secretary Emeritus of the American Institute of Mining Engineers, New York.

American Institute of Mining Engineers

On Jan. 27, a meeting was held in Washington of the members of the American Institute of Mining Engineers, who are also members of the U. S. Geological Survey, to consider the proposed amendments to the constitution of the institute. At this meeting were present, G. H. Ashley, state geologist of Tennessee; G. F. Becker; A. H. Brooks; E. F. Burchard; R. H. Chapman; Frank L. Hess; W. Lindgren; H. D. McCaskey; E. W. Parker; F. L. Ransome; C. E. Siebenthal; George Otis Smith; A. C. Spencer; D. B. Sterrett. Arnold Hague was prevented from attending, but he, as well as George P. Merrill, of the Nation Museum, and J. A. Holmes, of the Bureau of Mines, desire to express their concurrence in the action taken.

The following resolutions were passed after full discussion and without a single dissentient vote:

The members of the American Institute of Mining Engineers present do not approve of the proposed change of name of the Institute to "American Institute of Mining and Metallurgy."

The members of the American Institute of Mining Engineers present are not in favor of the change in classification of members on the basis proposed in the circular, which is not a reclassification based upon professional standing.

In the absence of a financial statement showing that an increased income is necessary, the members present are opposed to the proposed increase in dues.

A committee was also appointed to communicate the resolutions to the mining press in the hope of eliciting expressions of opinion. This committee consisted of Waldemar Lindgren, George F. Becker and A. H. Brooks.

Cause of the Wyoming Explosion

After a thorough examination by a number of the leading coal men in Wyoming, it is the consensus of opinion that the explosion at Susie, on Jan. 20, was due to a blown-out shot, as already noted in Coal Age, Vol. 1, p. 516.

The particular shots to which the cause of the explosion is attributed, were in room 8, in the second north entry. Two shots were fired in this room at about the time of the explosion, and it is possible that they were both fired simultaneously. The holes were drilled at right angles to each other, and there was evidence that one of the shots was "windy" or "blown-out." The mine has never been known to show any firedamp, which further strengthens the theory of a dust explosion. That the possibility of such an occurrence was appreciated by the management is shown by the fact that the mine was provided with a complete watering system for sprinkling; to this fact is attributed the local character of the explosion.

The coroner's jury examined a number of the leading coal men in the West, who were present shortly after the explosion, and found: "That the deceased came to their death by burns and asphyxiation, caused by the explosion, which might have been avoided by the proper placing of the shot."

According to the latest reports the fatality list totals 6 men, which includes those who died of their injuries since the explosion.

Switchboards for Small Plants

In small isolated plants and central stations it is desirable to keep the initial investment low and yet provide good service. To meet this condition, the General Electric Co. has placed on the market a line of small switchboards ranging in capacity from 1 kw. at 125 volts to 200 kw. at 250 volts.

The panels are made of dull black marine-finished slate, and are furnished with the necessary copper connections between busses, switches and circuit breakers, when the latter are supplied, together with the wiring on the back of the board.

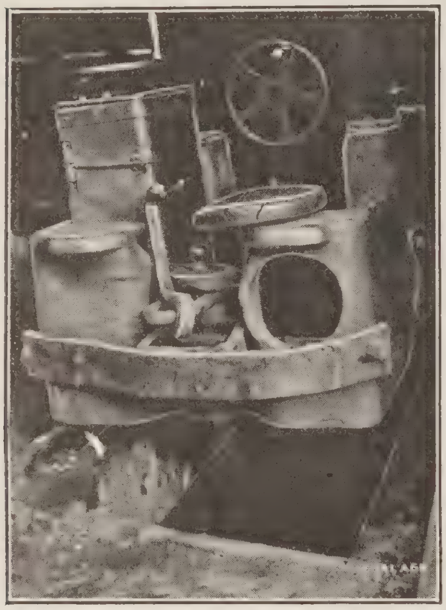
The instruments also have dull black finish and the current carrying parts on the front of the panels are polished and lacquered.

A complete supporting framework with necessary fittings is furnished with each panel, the small panels for wall mounting being provided with malleable-iron supports, while those for installation on the floor are provided with pipe supports.

Bulletin 4903 contains illustrations and descriptions of this line of panels in addition to complete information for ordering.

Good Service from a Mine Locomotive

The argument that good machinery needs proper care would seem to be denied in the locomotive shown in the accompanying cut. This locomotive has been running for five years in a Western mine. Operating on heavy grades, it has had a number of runaways, and the main frame has been repeatedly cracked.



Showing Mine Locomotive After Hard Usage

In spite of its dilapidated condition, it is still in daily operation, and is doing its work with little trouble. As an example of how much abuse mining machinery and electric locomotives in particular will stand, this locomotive is a valuable exhibit.

Twenty-first Bituminous District, Pennsylvania

By F. W. Cunningham*

The production of coal from this district, considering the depression of the industry in general, was above expectation, exceeding the tonnage from the same mines for 1909 by 17,442 tons, but falling 129,799 tons short of that produced in 1910. The drooping of the tonnage is accounted for in this district, partly by the fact that several of the mines are nearly exhausted and cannot maintain their usual output. One new mine is being opened by the Warner-Leonard Coal Co., near Fayette City, which, if its plans are carried out, will be a large producer.

There were 35 fatal accidents in the mines, being four less than in 1910. The accidents occurred from the following causes: 57.14 per cent. by falls of slate, coal and roof, being 4.40 per cent. below 1910; 28.58 per cent. by mine cars; 2.86 per cent. by blasts of dynamite; 11.42 per cent. by electricity. There were no accidents caused by explosion of gas or of coal dust.

The mines were never in better sanitary condition, or more carefully looked after by the mine officials than they are at the present time, and they are in condition to run a larger tonnage.

PRODUCTION OF COAL

Face Guard for Mining Stock

At the present time a great deal of attention is being paid in Great Britain to the physical condition of horses and ponies employed underground, and much is now being done to remove those objections which have been made to the careless treatment which is said in some cases to have been meted out to them. One indication of this admirable movement is shown in the illustration which gives a rough drawing of an eye protector guard which is being made by George Burnside, of Shiney Row, Fence Houses, in the County of Durham. The loss of an eye is, of course, one of the most painful accidents which can happen to an animal underground. Once a pony loses an eye, probably half the value of the animal is lost.

It consists either of copper or galvanized wire woven into a suitable mesh with rims and adjustments or straps for attachment to the bridle. All the wire ends are woven round the outer rims, and the protector being shaped to suit the eye is of great strength without having any needless weight. Should the horse or pony come into collision with any obstacle, such as a wooden door, the resistance is taken by means of the plate fixed to the guard, which plate takes its bearing on a leather strap which is attached to the bridle and comes down the forehead and face. It also has adjustments in the form of buckles which are attached to the outer rim of the guard.

The buckles which engage the straps attached to the bridle on the cheeks of the animal prevent the guard from touching any part of the head, and thus the horse or pony receives the force of the blow without any pain or fear of any damage to the eyes. The guard is attached to the bridle with suitable straps which can be easily removed for repairs without removing the bridle from the pony, and are suitable for fixing to any existing bridles. As the device is well ventilated it is cool, and this is a matter of great importance. There is, moreover, no interference with the sight, as the horses or ponies have their full front and side sights. This feature is most necessary as the side sight is important to underground animals, much turning having to be done in narrow spaces.

Horse Fitted With an Eye Protector

It is often found that ponies are nervous after accidents, and a valuable provision is made so that the bridle need not be removed in case the guard needs reblocking. In order to facilitate reshaping, hard-wood blocks are provided and mounted at the stable, which are so formed as to correct the distortion of the guard and to fit it when molded to its proper shape. A common cause of tender eyes in animals employed for underground haulage, is the lashing of wet canvas doors against their eyes, and the protector shown effectively obviates this.

The mesh which is usually adopted is ⅝ in., but this can be varied to suit local circumstances, and in some cases aluminum guards have been substituted for copper or iron. This simplicity of adjustment to existing bridles is a great feature in its favor, and it can therefore be imagined that the device is a great boon to underground horses and ponies.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Ventilation in Sinking Shafts

R. A. S. Redmayne, the chief inspector of mines in Great Britain, gives an account of the accident at the Thorne colliery, Yorkshire, England, which illustrates the care which should be used in ventilating shafts during the sinking process. He says that an accident occurred, Mar. 16, 1910, at Thorne colliery, when sinking operations were being carried on to reach the Barnsley bed. The shaft was 22 ft. in diameter, and was only 120 ft. deep at the time of the accident. A round of 15 shots in the bottom of the pit had been fired by an electric battery, each shot containing 1¼ lb. of gelignite. Immediately after the firing of the shot a foreman and laborers descended the pit in a hoisting bucket ("bowk"). On reaching the bottom of the shaft, about five or six minutes after the shot had been fired, the men began to cough, and several of them became very weak and ill.

A second gang of laborers descended and reached the bottom of the shaft about 15 min. after the first gang, and one or two of them were also affected by the fumes. During the shift several of the first gang became so ill that they had to cling to the rings of the shaft; but the significance of the symptoms mentioned was not realized by either the men themselves or those in charge of the work. The men temporarily recovered, with one exception, this man going to the surface an hour before the completion of the shift; the rest worked about three hours after the firing of the charge mentioned above. Then they went home, but during the night several of them became seriously ill, and one died about the middle of the next day (Mar. 17).

All the men who went down in the first bucket, and one at least of those in the second bucket, developed similar symptoms. No mechanical means had been taken to produce a ventilating current in the shaft, and the heat of the steam pipes used therein caused a current of air, which was depended upon to ventilate the workings. The shaft was wet; the amount of water being made being about 120,000 gal. per hour.

The symptoms show that those of the men who were affected by the poisonous fumes of the shot were suffering from the effect of carbon monoxide, and nitrous oxide poisoning. Prominent among these symptoms was a confusion of thought and expression, even when the persons affected thought themselves quite well (pointing to the presence of carbon monoxide), and violent coughing (pointing to nitrous-oxide poisoning). The inferences which may be drawn from this case are the following: That carbon monoxide was responsible for the more immediate symptoms, and the nitrous fumes for the bronchitis.

In Cornish mines, where it is seldom that more than 4 or 5 lb. of gelignite are fired at one time, cases of "gassing" are rare. On the other hand, accidents of this sort are common in the Transvaal, where heavy rounds of explosives of the nitroglycerin class are fired, and carbon monoxide is as often the cause of death as nitrous fumes, the latter being dangerous when a charge has failed to detonate.

But even with the best obtainable ventilation and the best quality of explosives, the conditions characterizing the present case would be risky, and it is remarkable that with such heavy rounds of shots that there had not been trouble at this work before. Possibly the explanation lies in the fact that the shaft not being so deep, the fumes cleared away sooner than was the case at the time of the accident; but it may have been due to the fact that the men did not, on previous occasions, descend to the bottom of the shaft so soon after the firing of the rounds of shots. Perhaps, too, on the fatal occasion, the climatic conditions were such as operated against the rapid carrying away of the fumes.

Briquetting Machines

We are indebted to *The Iron and Coal Trades Review* for the following descriptions of two large coal briquetting machines for installation in a South Wales briquet manufactory. One machine is the largest double-pressure briquet machine built in England up to the present time for the manufacture of briquets from bituminous fuel. Two 25-pound briquets can be made per stroke, the edges being beveled, and the briquets being branded on both sides. The output is about 25 tons per hour, equal to some 2200 briquets per day. The machine is extremely heavy, as may be well understood when it is noted that it will exert a total pressure of 320 tons upon the briquet.

Another machine, also made by Robert Middletown, of Sheepscar Foundry, Leeds, is built for the manufacture of small nut fuel, and can be designed to make blocks weighing from one to four ounces. Its output is from 10 to 15 tons per hour, according to the weight of the block produced. As usual, the molds are sunk in tires, being so arranged that the whole face of the roller is covered by the depressions, in which the material to be compressed is allowed to run. There are four rollers, two at each end of the machine with gears between them. The roller faces are made of steel, and after having the cups or molds carefully cut and polished in them, are heavily casehardened before being pressed onto the steel centers which carry them. The gearing is cut so that the cups come together. The bearings or brackets are very heavy, and the rollers are adjusted by wedges. The machine described requires only 15 to 20 horsepower for operation.

Grounding

The discussion of a paper on "Earthing, Earth Plates and Earth Detectors," by T. W. Ellis, at a recent meeting of the South Wales Branch of the Association of Mining Electrical Engineers of Great Britain, contained some interesting facts.

Sands and gravels appear to conduct principally by the moisture and damp clay in the interstices, but clays have a true conductivity, some of them giving less resistance than the water with which they are moistened. Some rocks have a conductivity depending not only on the water they contain, but also upon the nature of the rocks themselves.

RESISTANCES OF NATURAL GROUNDS

Natural conductor	Ohms per c.c.
Fresh rainwater	12,000
Stream, well and river water	2,400
Thames water (at London Bridge)	2,130
Sea water	350
Saturated solution of lime water	750
London blue clay	870
London red clay	950
Clay with sand	1,900 or over
Plastic clay	1,900
Same clay (dry)	1,850
Silver sand	6,400
Ordinary river sand	19,000
Whiting (levigated chalk)	1,900

These figures suggest that the excellent conductivities of clays are due to the fineness of their constituents and not so much to the conductivities of the particles themselves. Temperature is also a factor; water at 60 deg. F., which had a resistance of 2400 ohms, fell to 1400 ohms at 150 deg. F.

Long continued action of electric current lowered the resistance of soils, while a rest raised the resistance.

The resistance of a ground-plate 2½ ft. square is about ¾ of an ohm, if

sunk in the sea, 3 ohms if buried in pure clays, 10 to 15 ohms if in mixtures of both gravels and clays, and as high as 40 ohms when sunk in some mixtures of sands and gravels or of porous rocks. The least resistance of an earth connection that Mr. Ellis has yet measured was 7 ohms, and the mean resistance of a large number of measurements was between 15 and 20 ohms. In sinking a ground-plate, it is necessary to put it sufficiently deep to insure its being surrounded the whole year with soil saturated with moisture. It should be sunk in a hollow, and, if possible, beside a constantly running stream, with the top of the plate below the level of the bed of the watercourse. If sunk near a drain the plate should be placed near its under surface. If there are gas and water pipes, it should, where possible, be connected to them. Of course, a connection to a gas or water main is sufficient where such pipe is not likely to be cut for repairs. The resistance of an earth connection made to a water line may be but a fraction of an ohm. A number of small plates, sunk some distance apart, are a more efficient earth connection than one large one. They are still more effectual if the conducting layer of soil is shallow.

Weldless Chains

In a paper read by A. D. Strathern, on "Weldless Steel Chains for Mining and General Purposes," before the Manchester Geological and Mining Society, he said: "It is now fully 100 years since the ordinary oval-link welded iron chain was produced commercially. Robert Flynn, an Irish blacksmith, commenced making such chains at his forge in North Shields, in the year 1808, and from that time the chain-making industry has grown steadily until it now holds an important place in the world's manufactures. Stud-link chains, as used for ships' cables, were introduced in the year 1812 by Lieut. Brown, but since then practically no improvement has taken place in the manufacture of ordinary welded iron chains. Defects which experience has shown to be most common in welded-iron chains are: first, defective welds; second, the excesive weight of the chain, as compared with its strength; third, the absence of any allowance for wear on those parts most subject to abrasion; fourth, the want of a uniform standard of quality. In most cases, chains wear at the end of the links, where they bear upon each other; consequently the correct theoretical and practical design is to make the ends of the links of greater cross-section than the sides, and so provide for wear and tear, and at the same time give a greater resistance to deformation under strain."

Weldless Chains Stronger than Welded Chains

Some years ago Mr. Strathern invented the process of making weldless steel chains from cruciform bars by stamping or segmental rolling. A machine built in accordance with his design is now working successfully at Gartsherrie, near Coatbridge, and large quantities of chains are being produced regularly on this machine. Chains made by this process have the ends of the links materially thickened where the wear usually occurs, and the proof-load applied to these chains is approximately the same as the breaking load of a welded iron chain of the same size. The ultimate strength of these chains is approximately 100% greater than that of welded iron chains acceptable for British Admiralty Service. For example, a three-quarter-in. weldless steel chain, tested at Birmingham University, broke at 28 tons, whereas a welded iron chain of the same diameter would only be required to stand a breaking load, in accordance with the Admiralty scale, of 13½ tons. It is safer to lift 3 tons with a half-inch weldless chain than it would be to lift 1½ tons with one which is welded.

During the last few years weldless steel chains have been largely adopted for mining and general purposes. In many important collieries throughout the country they are being used exclusively for car couplings, cage bridles, and other chains.

Mr. Landless said that he had seen a weldless chain over a mile in length at work. It had been working for four years and had given great satisfaction.

Collapsible Air Ducts for Mine Fires

Gustav Ryba, Royal-Imperial Chief Mine Controller at Brüx, Bohemia, Austria, gives the following notes on the fighting of mine fires in the Zeitschrift des Zentral-Verbandes der Bergbau Betriebsleiter Oesterreichs:

The usual way of coping with a fire is by the use of props, boards and brattice cloth. But where the cross-section of the heading is too narrow to permit of the erection of such a side airway, air conduits can be used. These may be made of cloth, and can be folded up like Chinese lanterns as is shown in Fig. 1. They are easily carried from place to place. These cloth conduits are made and sold in Vienna. In order to prevent the collapse of the cloth cylinders with consequent obstruction of the air, they are stiffened by steel rings within.

Fig. 2 shows the use of such a temporary air duct placed in a vertical shaft. According to the data furnished by J. Jicinsky, a mine manager, 100 yards of horizontal air conduit can be laid in 15 minutes.

The ventilation may be obtained by a split from the main air current or from a small portable fan, driven by hand or water power.

COAL AGE

Electrical Supervision

The introduction of electrical machinery into mines has required from the personnel working therein, knowledge of an entirely new character. The result has been twofold. The mining companies have suffered from the incompetency of their men, and the men have suffered in varying degree from the lack of skill of their co-employees.

On only one ground, that of safety, is it permissible, within Constitutional restrictions, to urge the examination and licensing of any body of craftsmen. Nevertheless, as such a change might cause some additional expense to the coal companies, it would be well to supplement the consideration of safety by drawing attention to the advantage of having men of known efficiency. A shiftless way of operating, which burns out armatures, causes short circuits in coils, permits leakages along leads, leaves machinery where it is subject to moisture and corrosion, allows bonds and cross bonds to become loose, and imposes unnecessary resistance at joints, obviously is not profitable. The coal company is bound to pay the wage which will justify the acceptance of employment by competent men if it would secure economical work, and it will not cost any more to engage a competent and licensed man than one who is competent and yet unlicensed.

The licensing of the electrician should be by a special electrical inspector. The examination should cover many of the dangerous features in electrical wiring, and the operation of electrical mining apparatus. Every mine should have an electrician capable of installing simple equipment, or of supervising its installation. In small mines working 150 men the foreman could serve as electrician if duly qualified and licensed, but in larger mines, a separate man should be required. Perhaps, however, consideration might make the electric output the basis for division. There are logical considerations for either decision.

In England, the special rules, adopted in 1905 under the authorization conferred on the Home Office in the Coal Mines Regulation Act of 1887, require a competent person to be on duty above ground and another below when electricity of more than 200-hp. is being transmitted. The law is indefinite as to the meaning of competency and is made harder to understand by the further requirement that "every person appointed to work any electrical apparatus shall have been instructed in his duty and be competent for the work he is set to do." A degree of competency is therefore required which in any particular case would be hard to determine.

It may be added that any person appointed as superintending electrician should have opportunity at least four days in the week to superintend the condition of the wiring, bonding and machines, and to direct the men under his charge in the performance of their duties. If reasonably free from hampering non-supervising duties, such an electrician should be able to superintend both above and below ground.

The Minimum Wage

The situation in England is extremely interesting, the more that it shows the future trend of American unionism. If the American laboring man tends in himself to evolve on different lines from his English cousins, the force of example is almost sure to interfere with the simplicity of his evolution.

Say what we will, the American workman has in the past been willing to labor, on the whole, an eight- or ten-hour shift for an eight or ten hours' pay. But present signs indicate that he is not as willing to do it now as formerly. Ten or fifteen years ago a man was hired to help, much as on a farm, at every job that appeared.

But with schedules of wages immutably fixed by unions, a man will now do noth-

ing for which a higher rate is paid unless his pay is raised accordingly. To do so would be scabbing. Nor will the workman of today do work lower in the scale than that for which he was hired. This, he feels, would be socially lowering and besides might result in a reduction of his wages. And neither will he do another man's work, although it is paid for at a rate identical with his own. That might cause his fellow workman to be laid off and would be resented. All the union permits him to do is the work for which he is specifically employed. Otherwise he must remain idle.

It is to be regretted that we have about the mines so many different jobs with fractional differences of pay; this condition results in the establishment of so many castes, that every man awaits, albeit with no anxiety, for the approach of that particular piece of work for which he was specifically engaged. Of course, this incapacitating condition has gone further in England, still further in France, and further yet in India. But we are traveling along the same road fast enough to arouse concern, and, to prove this contention, all we need to do is to recall how business was conducted only ten years ago; how every man ran forward to give a lift, hustled the rock out of the mine cars and snow out of the gondolas for the morning start.

It is different now; the men inside wait for cars and earn a lessened wage because the employee without warms his hands while certain men hired and labelled drivers, rockmen or snowmen, have to do their work begrudgingly alone. The spirit of emulation, the spirit of "all together, boys," has gone with the passing years and a new condition faces us.

The deliberate and intentional reduction of the workman's activity has as yet scarcely invaded this country, but, as we show a great aptitude for embracing alien faults, we may anticipate its arrival. The English workman lays less brick and digs less coal, not because he is a less competent fellow. He is as efficient, physically and mentally, as the average employee in America, reckoning the native and foreign admixtures. He digs less because he wills to dig less. He lays less brick because he wishes to lay no more. The will and not the ability is lacking. He has shortened the working hours by union regulation and by act of Parliament. We wonder he has not still further shortened them—so little has he concluded to do.

The minimum wage is planned as a provision whereby the man who does not earn enough to cover the cost of necessities, may be presented with a living wage at the expense of the coal owner. There are some old men, whom this new plan will inevitably force out of the mines; also, many incompetents will be weeded out, while the lazy will have to travel the road of the weak. And so perhaps, on the whole, the operator will not suffer. But it will be a severe burden on the resources of the English nation to support the old and incompetent whose capacities are perhaps only half that of normal men in their prime, and who, by this ill-considered provision, if extended to other forms of labor, must be thrown entirely out of all work.

The minimum wage will leave the operator just about *in statu quo* and the miner just a little worse off than he was before, for he will be thrust out of his work in his old age. The principle is bad. We may overlook the disputes it will occasion, the bitter enmities and feeling of desperation which will arise, when men are discharged for the incapabilities of age. We can hear them repine that it is "a sin to grow old."

But apart from all this, the introduction of the minimum wage is a sign that the economic reasoning of the laboring classes of England is essentially wrong. We have never been absolutely sure that labor was not the source of all wealth, seeing that capital is but stored labor, and land but the body on which labor operates. But if, as the workers significantly claim, labor is wealth, then where is wealth without labor? Will the country of England, and the miners of England, an important part thereof, accumulate wealth by rest? The "idle rich" constitute a great international problem, but still greater is the problem of the "idle poor," for if no one will work, there can be no wealth.

We can see some sense in a raise in wages. In the readjustment, the capitalist may write off a little of his profits and labor thus secure a larger proportion. Moreover, if, of all trades, the workers in one industry get the earlier raise, then those workers will continue to score by greater purchasing power until the index of staples takes a new rise. But what gain is there in decreased production? It does not affect the distribution of wealth, but merely its total amount. There can be no gain to labor from a decrease of production. The bee might as well say, "I will be a wasp and store no honey," as the worker say, "By working less, I shall live better."

It is needless to say there is no advantage in overworking, and some Americans, many miners among them, are working too hard. But there is no greater truth than this: When men conserve their labor to a degree which does not aid in preserving either life or effectiveness, they do not conserve, but rather destroy the wealth which that labor represents.

Dusty Gob Headings

According to Mr. Mavor, the percentage of coal dust on floor, sides and roof of a rough heading amounted to 70, 24 and 6% respectively of the whole dust found. Where the sides of a roadway are gobbed, the accumulated dust on the sides may be a large percentage of all the dust present. The Briceville explosion may well have been made more severe by the dust on the extended gob-walls at the sides of the butt-headings.

It may be said, however, that the advocates of schistification favor a rough heading, along the sides of which large masses of stone dust may be conveniently distributed to permeate the ventilating current at the first disturbance of the air or vibration of the measures.

Coal Liming

The English gas plant owners have shown a revived interest in coal liming. The process consists in mixing ordinary limestone finely powdered, with the coal as charged into ovens or retorts. The advantages claimed for it and which have actually been obtained at the Cheltenham Gas Works, England, are: Reduction of sulphur compounds in gas, increase of gas yield and illuminating power, and the production of suitable metallurgical coke from high sulphur coals, by reason of the sulphur combining with calcium, the body thus formed in the coke, calcium sulphide, being a compound of sulphur more or less inert when used in the process of reducing iron from its ores.

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Sealing off a Mine Fire

(Continued from Feb. 3)

Letter No. 18—As to the proper method to follow in stopping off a fire that is located at the face of a pair of entries, I wish to say that from my experience, (and I have been to a great many fires) I would always put my first stopping in the intake side as close to the fire as it is possible to get.

I would cut the air off from the fire even though I had to put up a temporary stopping and the permanent one later on. I should try to prevent an explosive mixture forming. I have never known a case where I would place the first stopping in the return. Other men may differ from me, but this is my opinion. I am

attaching hereto a little sketch, showing where I would put the first stopping, if it were possible to get so close to the fire.

RICHARD NEWSAM,
Pres., Illinois State Mining Board.
Peoria, Ill.

Letter No. 19—I have had some personal experiences in dealing with mine fires, and have had to play "tip and run" in at least one of these. While recognizing the fact that it is often impossible to approach the return side of a fire that has gained considerable headway, generally speaking, I should certainly make every possible endeavor and close the return airways first.

By closing the return side first, when it is possible to do so, I confine all the products of combustion to the area of the fire; and these assist greatly in deadening and finally in extinguishing it. These confined gases expanded by the heat of the fire push back the fresh air that would enter the intake end.

If, on the other hand, that end is sealed first, there is the greatest likelihood that sufficient fresh air will be pent up inside or behind the stopping to keep the fire alive and to make the gases generated highly explosive. My advice is, whenever possible, close the return end first and make it tight as wax. I would like to go more into detail in the important discussion you have started, and may do so a little later; but time will not permit me to do this at present.

JAMES ASHWORTH.
Vancouver, B. C., Canada.

Letter 20—It never occurred to me that there was any other way of sealing off a mine fire than by placing the first stopping in the intake entry, just inside a crosscut which could be quickly opened to allow the air to short-circuit, and then to build the second stopping in the return. However, there are always two sides to a question and this one was submitted to three well trained, experienced coal-mine superintendents in the Illinois field, and their answers published herewith indicate how mining men differ on problems supposedly simple and generally assumed to have been solved in the early days of mining.

This solution is from a superintendent working in a field subject to gob fires:

> If I had a fire to deal with in the face of an entry, I would undoubtedly close the return-air side first, especially if the coal was giving off marsh gas, for the reason that when you close the return side of the entry, the gases given off by the fire would drive back the fresh air on the intake and eliminate the possibility of sealing up a large amount of fresh air with the fire.

The following is from a man in active charge of gaseous mines, who has had wide experience in fighting mine fires:

> I would build the first stopping on the intake, in order to stop the air current from blowing on the fire, as quickly as possible. I do not think the smoke would be as bad to work in on the return, with the first stopping on the intake, as it would be if we attempted to build it on the return first.

This answer is from an experienced superintendent, who has had a number of fires to subdue:

> My opinion in this case, confining myself to the simple case of a mine fire, and assuming, of course, that there is no gas to contend with, would be to put the first stopping in the intake, which could be done without the workmen being greatly handicapped by smoke. When that first stopping, blocking off the air, was built, the smoke on the return entry would be reduced, and the men could erect the return-side stopping without difficulty.

The assumption that there is no gas is wrong, since any fire may generate enough carbon monoxide or other explosive gases to make an explosion imminent, and the only safe way is to assume gas to be present and act accordingly. An analysis of the case presents the following:

Fan Exhausting

Stopping placed on intake—Would involve sealing up some fresh air in that entry, and fan would draw gases and smoke down the return and into the workings, making more difficult and dangerous the work of placing the second stopping.

Stopping placed on return—Less fresh air would be sealed up on account of the gases and smoke backing up and filling the intake. This plan would prevent the dissemination of smoke and gas through the mine.

Fan Blowing

First stopping placed in intake—Some air sealed up; this method relieves intake of ventilating pressure and allows gases to issue from coal, possibly creating a dangerous condition.

First stopping placed on outlet—Less air would be sealed up with the fire on account of smoke and gases filling the entry while the stopping is being built and smoke backs up into the intake; also when the second stopping is built, the minimum amount of air would be sealed up in the fire zone.

The result of this hurried analysis seems to prove that the fire stopping should be built in the outlet, regardless of the plus or minus water gage; first, because it permits sealing up the entry with the least amount of air; second, it prevents gas and smoke filling up other parts of the mine; third, it does not involve danger of drawing gas or explosive mixtures over the fire.

It does appear, however, that these arguments are more or less theoretical and the conclusions far-fetched. About the only way a man can get to a mine fire (without a helmet) is by following the air; when he gets as close to the fire as the heat or smoke will permit, the nearest crosscut is opened, the air short-circuited and the two stoppings (generally a curtain first) should be built practically simultaneously, if the force of men is large enough. The first one to be finished, of course, will be the one easiest to get in place on account of height, roof, floor, etc.

Probably the reason the intake stopping is generally erected first is because the men can work in better air, and for the reason that material and tools are carried in along the intake airway, and it is natural to drop them at the last crosscut and build the stopping there rather than drag them through and work in the smoke. These are the actual conditions facing the men doing the work, and since there are no positive reasons for doing the job differently, you generally find the

first stopping in the intake, especially when working on a serious and dangerous fire.

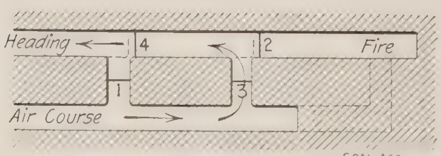
I am sure that the amount of air sealed up in building the stoppings would not make an appreciable difference in the life of the fire. The oxygen behind the stopping that aids the combustion is either from disintegration of H^2O, or is sucked through the stoppings by the contracting gases on account of the volume being reduced by cooling. I think the best thing to do is to get the stoppings in place as fast as conditions permit (regardless of which one is first) and then make them *tight*.

JOHN A. GARCIA,
Mining Engineer.

Chicago, Ill.

Letter No. 21—In answer to the question, "Which is better, in sealing off a mine-fire that has gotten beyond control; (1) to place the first stopping on the return side of the fire, or (2) build the first wall on the intake side of the trouble?" will say that I assume the fire is near the face of a heading and has assumed such proportions as to make it impossible for men to reach it, and for this reason it has been determined to seal it off. The problem is what is the best way to go about doing this.

The accompanying sketch shows the assumed location of the fire in a heading which is somewhat in advance of the air.



SHOWING LOCATION OF STOPPINGS AND DIRECTION OF AIR CURRENT

The arrows indicate the direction of the ventilating current. If I could do so, even by building a temporary brattice, as shown by the dotted line, I would build the first stopping or brattice at 2. This should temporarily be constructed of wood so that it may be put into place with great rapidity, and if thought desirable, a stone or other more permanent brattice could be built outside of the wooden one afterward. This would effectually cut out any possibility of the fire spreading, and after the brattice 2 had been built, or in fact during its construction, the air-course could be extended as indicated by the dotted lines. This, if necessary, would make it possible, after making a small opening in brattice 2, to reach the fire with water-hose or enable it to be attacked by other means.

In case the brattice 2 could not be built at the point indicated, I would build it at point 3, and, as the air-course was being closed up at this point, the brattice could be removed, after which brattice 4 could be built with the aid of the brattice or curtain shown by dotted line. After brattices 3 and 4 were put in, the air-course could be extended as shown by dotted line, and the fire attacked as indicated above.

As to which one of the brattices, 3 or 4, should be built first, the practicable way would be to follow the plan indicated above; that is, build brattice 3 first, for the reason that the air-current would keep away any smoke to interfere with its construction, and after finishing it, brattice 4 could be built with the aid of the brattice or curtain shown by dotted line. If it would help and was necessary, a part of the ventilating current could be allowed to pass through brattice 3 by making a small opening in it.

Of course, in the case of almost any mine-fire the mode of procedure is much modified by conditions and these conditions might cause a change from the plans I have outlined above.

I have not taken into consideration the presence of explosive gas as that point is not raised in the question. This point, however, might cut a considerable figure and call for special consideration and precautions.

ERSKINE RAMSAY,
VICE-PRESIDENT.

Pratt Consolidated Coal Co., Birmingham, Ala.

Letter No. 22—In my judgment, the first stopping should be placed on the intake airway, for, under the circumstances, it is essential that it be built as quickly as possible and it is evident that more rapid work can be done in the clear air of the intake than in the smoke and fumes of the return; but, even if by the use of oxygen apparatus or other device it could be constructed as readily and quickly in the return as in the intake, I would still select the latter as the right place for the first stopping.

In the case before us, two things should be kept in view; (1) the most effective means to keep the fire from gaining and to subdue it, must be applied as expeditiously as possible, and (2) the safety of the men doing the work must have the most careful consideration. The last is of paramount importance.

The fire, as stated in the question, is beyond control by ordinary means. Therefore, if the first stopping is started in the return, it is apparent that the fire, with a practically undiminished air supply reaching it by way of the intake while the work of building the stopping is going on, will continue to gain materially and the consequent increased intensity of heat, the greater volume of poisonous fumes in which the men must labor, the increased danger from roof falls and other difficult conditions, will make fast effective work almost impossible, and may even force the workmen to quit the job before it can be finished.

The conclusion that the erection of the first stopping in the return is a protection against a possible explosion is not sustained by the facts. An explosion of a mixture of combustible gases and air, or coal dust and air, may occur with explosive results on the intake side of the fire, where air is present in sufficient amount and purity to support combustion. Explosions have occurred in just this way, and that danger is not averted or reduced materially by starting the first stopping in the return airway.

If the first stopping is started in the intake, the earliest possible check of an excessive and highly dangerous draft along the floor in the intake toward the fire is provided. As work on the stopping progresses, the excess air supply through the intake is steadily reduced, resulting in a material increase in CO_2 in the return, and therefore greatly lessening the possibility of an explosion in that region. As the stopping nears completion and the air supply becomes more attenuated, the products of combustion will spread further out from the fire along the intake and the additional short time needed to close the stopping may be considered a critical period, but undoubtedly this period of danger of a possible explosion and the danger itself are much less than under the attempt to place the first stopping in the return.

It may be held that the inclosing of fairly pure air between the completed stopping and the fire still involves the danger of explosion. This contingency appears to be remote. The inclosed air supply is of fixed and limited amount, and of a rather stationary character; it cannot advance freely toward the fire and what little advance there may be is speedily checked by the rapid rise in its temperature. But, supposing that under such unfavorable conditions and in the presence of a considerable amount of CO_2 and other noncombustible gases, an explosive mixture could be produced near the stopping, there is still no imminent danger because the means of ignition are absent and the mixture cannot get to the fire without losing its explosibility.

After the completion of the first stopping in the intake the possibility of an explosion on the return is practically eliminated. It is true that the return for a considerable distance outward from the fire is filled with hot gaseous matter, but the bulk of it is unfit to support combustion, and what combustible gases may be present near the fire, cannot be ignited because of lack of sufficient air.

Naturally, after the closing of the intake stopping, an air movement in the return toward the fire will set in, but the air, now befouled more or less by CO_2 and otherwise vitiated, can only make comparatively slow progress in that direction because its advance is steadily opposed by the resistance of the stretch

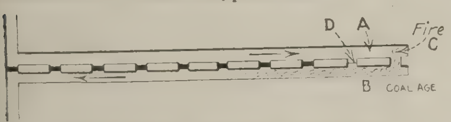
of heated gases, intervening between it and the fire, a resistance that can only be overcome by a gradual reduction in their temperature. In the meantime, the men building the stopping in the return can labor under more favorable conditions, permitting faster and better work.

I have kept the matter of the possibility of an explosion in connection with a mine fire in the foreground because it appears that the consideration of this contingency is the underlying cause for the difference of opinion regarding the selection of the right place for the first stopping. But while the matter deserves careful attention, it should be remembered that experience has shown that the danger to life and property from the direct action and smoke of a mine fire that is getting beyond control by ordinary means is vastly greater and certainly more immediate than the danger from the more remote possibility of an explosion. The exigency of the case demands that the greater danger receive first consideration; therefore, its main cause, the strong draft playing on the fire through the intake, should be removed at the earliest possible moment. In my judgment, this can be accomplished in the most effective manner and in the shortest space of time and without increased danger from any other source by erecting the first stopping in the intake.

John Verner.

Chariton, Iowa.

Letter No. 23—In reference to the treatment of a mine fire, many so-called authorities recommend sealing off the return first. I am sorry to say some textbooks advocate a like method. One I remember says in addition: "Many valuable lives have been lost and many disastrous explosions have occurred through sealing up the intake first." However, they do not give instances of these explosions.



Mine Fire at Face of Entry

The fact is, I have put out several fires, and have always been successful with them. My plan is to carry the air up as *close* to the fire as possible, which gives my men good air to work in. When I find it is impossible to extinguish the fire, I seal up the intake in *good* air to the last inch, then get a hole through the first crosscut behind me and build my last wall, forcing the warm fumes to the top by a temporary partition of cloth or board, which I arrange to have handy.

Just imagine a fire at the face of a pair of entries giving off CH_4, the gas burning in the coal at point *C* (shown in the sketch). Assume that said entries contain a pair of concrete-stopped crosscuts 2000 ft. from the main entries. Do you suppose a fireboss, foreman, or underground manager would lead his men up the return to *B* in all these fumes? Would he not rather go to *A* in good air and seal the intake there; then have other men open the crosscut *D*, and seal up *B*? Furthermore, how could an explosion occur at *A* when the gas was already ignited?

After putting out the flames by smothering, I would open up the return to see personally whether the fire was out before I would turn on the fresh air.

Joseph Virgin.

Plymouth, W. Va.

Mr. Garcia Replies to Mr. Norris

Please enter my protest against the assumptions and recommendations in letter No. 16 on mine fires by R. V. Norris, published in your issue of Feb. 3, 1912. Mr. Norris advises that we build the first stopping in the intake entry in order to reduce the amount of gas given off by the fire, etc., and I thoroughly agree with him as to location of first stopping, but strenuously object to the statement following, i.e., "this procedure would be reversed in case the workings gave off a large amount of explosive gas."

There are always explosive gases given off by mine fires; at least there are gases, the composition of which we do not know at the moment, and the only safe procedure is to assume them explosive and direct the work accordingly. Men who "assume there is no gas" belong in the category of those who "didn't know it was loaded" and should be kept on top whenever there is a fire in a mine and help needed below.

Mr. Norris also states that it would be a good plan to reverse the air after placing the first stopping in the intake in order that the second stopping might be built in fresh air. What a fatal mistake that would be! Suppose we were at work building a stopping in the intake near an open crosscut, and the fan was blowing air; what would happen if someone reversed the fan so it would exhaust? All the smoke and gas in the return would at once be pulled out on us, and the suction would draw the thick smoke and heavy gases and possibly the fire through the crosscut and force a hasty retreat and perhaps cause an explosion.

Reversing a fan is a dangerous and questionable proceeding at best, and under circumstances such as outlined above, would not only lose the fight, but endanger the lives of the men, unless it is assumed that the men all leave the mine when the air is reversed, and then what happens to the fire while all this is going on? Reminds one of the fellow hanging to the bridge above the rapids, and who, growing tired, said to a companion dangling at his heels, "Wait a bit, till I spit on my hands."

J. A. Garcia,
Mining Engineer.

Chicago, Ill.

[*In our issue next week, we will publish letters from Carl Scholz, president of the Consolidated Indiana Coal Co.; J. T. Beard, associate editor of* Coal Age, *and other well known engineers.*—Editor.]

Textbooks at Examinations

I was interested in the letter by Iago, appearing in Coal Age of Jan. 20, and wish to respond to his request for opinions as to the use of textbooks at fireboss and mine-foreman examinations. I feel that I am entitled to speak on this subject, as I shall never forget the nights that I struggled with a problem in square root or a formula in ventilation, when my physical weariness was positively painful, and it is a well known fact that at a time like this the brain is in no condition for such strenuous work as technical mine problems. Although I believe a certain amount of technical proficiency is necessary in a foreman or fireboss, yet there are good men who have given up the struggle for a certificate because of the conditions under which they have had to prepare for the usual examinations.

While, of course, it is absolutely necessary that a mine official should have a general understanding of the principles of mining, yet many of the rules and formulas which some of us have wrestled with for hours are of less actual value to us in our everyday work than we ourselves would probably care to admit. After all, the real test of a mine foreman or fireboss is his judgment as a practical man, rather than his ability to memorize rules and formulas, and I know of a number of men, of more than usual ability, who have failed under this latter superficial test. In fact, I have in mind at this moment, two mine foremen, one in Ohio and one in West Virginia, who were the best mine officials I ever knew, and yet could not memorize any particular rule of mathematics or any particular clause of the mine law.

It seems to me that one of the chief duties of an examination board should be to draw out the character and personality of the applicant, ascertaining as far as possible his knowledge as to the general operation of mines, and his views regarding the common dangers, safety measures, appliances and like matters.

In my opinion the oral examination of mine foremen and firebosses should play a much larger part than it does at present. Given 15 or 20 min. conversation with a man, a board of examiners should be able to tell whether or not he is qualified to manage a mine, just as any other man of experience could determine this fact under like circumstances.

Marianna, Penn. Sim Reynolds.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Thawing a Frozen Pipe Line by Electricity

A neighbor has 600 ft. of a 2-inch iron pipe, used as a supply line, frozen. He has ample electric power at command. Is it possible to use this power to thaw out the pipe line and what arrangement is necessary for this purpose?

C. B.

Shaw, W. Va.

Electric power has frequently been used with great success and economy in thawing out a frozen pipe line. Success, however, in any particular case, will depend on at least two essential conditions; namely, (1) a sufficient electric power transformed into a current of high amperage and relatively low voltage, depending on the size, length and conductivity of the pipe, which can only be definitely determined by experiment; (2) a sufficient insulation of the pipe line throughout the length of the frozen section to confine the electric current to the pipe without undue loss of power.

The principle involved is that if a current of sufficient strength is passed through the pipe the resistance developed may be such that the pipe will heat and the ice be melted. The resistance and consequent heating of the pipe will depend on its electrical conductivity, for any given current. The metal cross-section and its relative conductivity and insulation, in a way, determine the necessary amperage of the current, while the length of the frozen section suggests the voltage required. These data must be ascertained by an electrician, on the ground. A special transformer is generally required as the ordinary type will hardly be capable of giving the required voltage and amperage. This must be ordered to suit the conditions, which should be submitted in detail to an electrical supply company.

Authority to Act as Mine Foreman

Suppose, at a mine employing both a mine foreman and assistant mine foreman, the assistant foreman leaves. The mine foreman at once appoints one of his regularly employed firebosses to take the place of assistant mine foreman.

But, suppose the mine foreman suddenly resigns his position as foreman and goes away, whom could he leave in charge of the mine until another mine foreman can be secured to take his place?

Subscriber.

Newcomer, Penn.

The bituminous mine law (1911) of Pennsylvania, Art. 24, Sec. 9, makes it "unlawful for any operator, manager, or superintendent to employ as mine foreman in any mine, or as assistant mine foreman in any gaseous mine" any person not holding the proper certificate of qualification or service. The same law, however (Art. 4, Sec. 1), permits the assistant foreman, in the temporary absence of the foreman, to perform all the duties of the latter.

No provision is made in the law, as far as we know, for a fireboss to assume the duties of assistant foreman in a gaseous mine. He must hold a certificate of qualification for such position before he can be legally appointed to fill the place. The requirements for the two positions, however, are quite similar; the candidate for assistant foreman in a gaseous mine being required to obtain 70% in examination, while the candidate for fireboss need secure only 65%. Each must pass an oral examination in explosive gas, in addition to the usual written examination.

No examination seems to be required, in the law, for the position of assistant foreman at a non-gaseous mine.

Pumping At a Slope Mine

We have a slope dipping about 11% for 2400 ft. At the slope bottom we have a borehole that is 320 ft. deep. About 1000 ft. from the top of the slope we have another borehole that is about 208 ft. deep. The drainage above the upper hole is about 400 gal. per min., while that between the upper and lower holes is practically 200 gal. per min.

Before arranging the system of pumping in this slope we would like to have your opinion as to what would be the most economical system to adopt—to establish a pumping station at each borehole; or to run all the water to the lower station and have but one pump, which would save the expense of a pump runner.

Borehole.

Dunlo, Penn.

Two pumping stations would practically double the cost for attendance, supplies and repairs, while it would save the power and consequently the fuel required to raise 400 gal. of water per min. a vertical height of 320 − 208 = 112 ft. The saving in fuel would amount to

$$\frac{400 \times 112}{600 \times 320} \times 100 = 23.3\%$$

According to figures based on a careful estimate of the cost of pumping, at the Short Mountain Colliery of the Lykens Valley Coal Co., made by R. V. Norris, chief engineer for the Pennsylvania R.R. coal companies, during the great strike of 1902, when it was possible to obtain reliable data in this regard owing to the complete cessation of other mining operations, the cost of fuel, reckoned at 50c. per ton, may be taken as $0.0188 per 1000 gal. of water, lifted a vertical height of 1000 ft.

In the present case, the quantity of water that must be handled each 24 hours is

$$600 \times 60 \times 24 = 864{,}000 \text{ gal.}$$

With a single pumping station at the foot of the slope, this water must be lifted a vertical height of 320 ft., at a cost for fuel of

$$0.0188 \times 864 \times 0.32 = \text{say } \$5.20 \text{ a day.}$$

If a pumping station is located at the upper borehole it would effect a saving in fuel of about $0.233 \times 5.20 =$ say $1.21 a day. It would, however, require another pump runner and this, with the additional cost for supplies and repairs, would increase the expense for pumping about $2 a day. As a result of maintaining two pumping stations, therefore there would be a net loss of about 80c. per day.

[In a second letter, our correspondent suggests placing a pump at the lower sump and pumping all the water from this station. He asks if a pipe be laid to conduct the water of the upper basin to the pump, and a valve be provided at the pump to shut off the flow of water from above while pumping from the lower sump, could not the head due to the vertical height of the upper basin above the pump be made available, so that when the pump is handling the water of the upper basin it would only be working under an effective head corresponding to the vertical height of the point of discharge above the upper basin. We answer, Yes, by a proper arrangement of the pipes and two valves, one at the foot of the slope pipe and the other in the suction pipe below the entrance of the slope pipe.—Editor.]

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions for Beginners

Enlarging An Airway

Ques.—An air course is 3x3 ft. and 1050 ft. long; and it is decided to enlarge its section and make it 6x6 ft., to furnish more air for the mine. The work of enlarging the area was started at both ends of the airway and continued till but 50 ft. remained to be completed. It was then stopped. What, if any, effect will be produced in the circulation of air in this airway?

Ans.—The airway was originally 3x3 ft., 1050 ft. long; it is now divided into three sections, which are continuous or tandem to each other. Two of these sections are 6x6 ft., 500 ft. long; and the remaining or middle section is 3x3 ft., 50 ft. long. The simplest and quickest way to ascertain the effect of this enlargement on the circulation of air is to calculate the value of the potential, first, for the original airway, and then for each of the three sections into which this airway is divided. The first and last sections being alike, however, it is only necessary to calculate the potential for one of them. Thus,

Potential Values of Airways

$$\left(X^3 = \frac{a^3}{lo}\right)$$

Airway, 3′x3′, 1050 ft. long,

$$X_0^3 = \frac{9^3}{1050 \times 12} = 0.0578$$

Two sections, each, 6′x6′, 500 ft. long,

$$X_1^3 = \frac{36^3}{500 \times 24} = 3.888$$

One section, 3′x3′, 50 ft. long,

$$X_2^3 = \frac{9^3}{50 \times 12} = 1.215$$

If the power on the air remains unchanged; in other words, for a *constant power,* the quantity ratio is

$$\frac{q_2}{q_1} = \sqrt[3]{\frac{X_1^3\,X_2^3}{X_0^3\,(2X_2^3 + X_1^3)}}$$

$$= \sqrt[3]{\frac{3.888 \times 1.215}{0.0578 \times 6.318}} = 2.347$$

On the other hand, if the ventilating pressure remains unchanged; in other words, for a *constant pressure,* the quantity ratio is

$$\frac{q_2}{q_1} = \sqrt{\frac{3.888 \times 1.215}{0.0578 \times 6.318}} = 3.596$$

That is to say, if a certain power will circulate 10,000 cu.ft. of air in a 3x3-ft. airway, 1050 ft. long, the same power will circulate 23,470 cu.ft. after the airway has been enlarged to 6x6 ft. for a distance of 500 ft. from each end, leaving a section 50 ft. long, in the middle of the airway, the same size as before; namely, 3x3 ft.

Or, if a certain ventilating pressure or water gage circulates 10,000 cu.ft. in the original airway, the same *pressure* will circulate 35,960 cu.ft. after said enlargement is made.

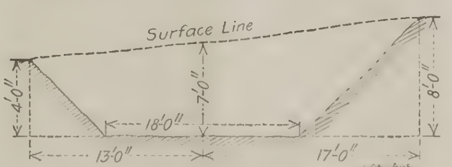
[The above question is practical and one that every mine engineer and ambitious mine foreman should be able to work out at leisure, but it is too difficult, and has not been sufficiently explained in the mining textbooks in common use to warrant its being asked in a mine foreman's examination—Editor.]

Surveying, Calculating End Areas, Excavation or Fill

Ques.—Give a practical and simple formula for the exact calculation of end areas, in excavation work, where the center and side cuts and the width of the roadbed are given, and the side slopes are 1 : 1, or at an angle of 45 deg.

Ans.—The following rule is used frequently in railroad-surveying practice:

Rule—Multiply the sum of the distances out, or the total distance between slope stakes, by one-half the center cut (or fill); again, multiply the sum of the side cuts (or fills) by one-fourth the width of the roadbed; add these products together, and their sum is the end area required.



Cross-section of Excavation

For example, Fig. 1 is a diagrammatic sketch showing the cross-section of a cut made for a siding, at a coal mine. The center cut is 7 ft. and the two side cuts 4 ft. and 8 ft., respectively; the roadbed is 18 ft. wide. The area of this section is found readily, as follows:

$$(13 + 17) \times \frac{7}{2} = 105$$

$$(4 + 8) \times \frac{18}{4} = 54$$

Total area 159 *sq.ft.*

Indiana Questions

Hoisting Engineers' Examination

Ques.—(a) Where should the brickwork close in on a boiler? Give reason. (b) What is a blister on a boiler and how is it produced?

Ans.—(a) The brickwork must meet the boiler below the low-water line, so as not to expose the plates to the fire above the water level in the boiler, which would result in overheating, burning and blistering the iron.

(b) A blister, in boiler practice, is a small nub, or a number of them together, formed on the surface of a boiler plate exposed to the fire and showing that the iron has been burned and its strength impaired. The blister is the result of the local overheating and burning of the iron, owing to a strong concentration of heat at one point, because crustation or other impediment has prevented contact of the water with the plates.

Ques.—(a) Is a gage-cock or a water-glass to be preferred, and why? (b) If the glass water gage of a boiler in your charge should be broken when the boiler is under steam, what would you do?

Ans.—(a) The gage-cock is not only more reliable as furnishing positive evidence of the true water level in a boiler, but it is less liable to accident.

(b) Close the stop-cock of the gage below the broken glass first, and after that close the upper cock. To close these cocks while steam and hot water are issuing in scalding jets and sprays is practically impossible, unless the fireman has had the foresight to provide himself with a long-handled tool by which these cocks can be turned at a safe distance, or unless he can secure a waterproof covering, under which he can approach and close the cocks. If the upper cock is closed first the steam pressure in the boiler will throw the water out in a scalding stream.

Ques.—A boiler to be run under a steam pressure of 100 lb. per sq.in. should be tested to what hydrostatic pressure to insure safety?

Ans.—The regulations in different cities and states with respect to boiler inspection require a hydrostatic pressure varying from 35% to 50% in excess of the desired working pressure, for boilers to be operated above, say 25-lb. pressure. A boiler to be run at a gage pressure of 100 lb. may be tested properly to 140 or 150 lb. hydrostatic.

For the Betterment of Living Conditions in Mining Communities

Colliery Villages

By F. A. Boag

The Garden City Association of Great Britain has made the suggestion for village planning, embodied in the second design accompanying this article. While not an advocate of the spending of money in elaborate surveys of circular and parabolic curves, it seems to me that the idea has a real value. In the second plan, there are as many houses, namely 75 as in the first. There is less length of road to maintain by 425 ft. and a far more desirable appearance is presented. With a trifling change in the plans the houses might be converted into detached cottages, thus reducing the fire risk and promoting privacy.

Street Curvature

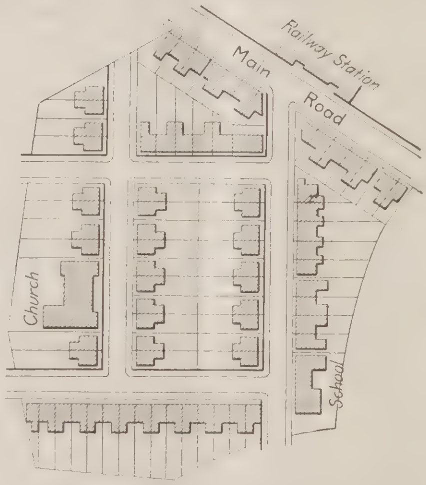
The severe straight lines by which we lay out our colliery villages makes them undesirable. These lines have been rendered necessary largely by the inefficiency of our methods of sanitation. It is evident that in the Garden City plan, some provision has been made for the care of fecal wastes, or otherwise the restriction of the back yards would be inexpedient, though with a little more land available this sewerage would not be absolutely necessary.

In the anthracite regions some of the villages have sprung up along crooked township roads and their appearance is far more inviting than are the stiff rows in those more pretentious villages where the intention is apparently to make a transplanted fac-simile of a city block.

As I have said, I would not advocate elaborate staking, but I would curve the streets to accord approximately with a rough survey previously made. Thus good grades could be obtained, trees of more than usual beauty could be preserved and the town would look more like a village and less like a slum. In many cases such grouping would enable houses already in existence to be left in position and large rocks would not have to be blasted and removed. Not infrequently such rocky masses might even be used to enhance the appearance of the village. There has been hitherto an expensive desire to fit the sites to the plan rather than the plan to the site with resultant loss of beauty, money, comfort and rapidity of construction.

Social Centers

Our mining engineers pay a fetish worship to the straight line, giving us long streets ending in vistas of smoky coke ovens, washer discharges, tumbling prop piles and unsightly rock dumps. If the surrounding country is undesirable, the village should be built so as to shut out the undesirable views; if beautiful it should be planned to utilize all the beautiful features. Centers should be established so that a few desirable tenants can together create a little world of their own, where their efforts in promoting beauty may not be marred by slovenly beer-guzzling neighbors who have no sense of the fit in rural life.



A Rectilinear Plot of a Colliery Village

A center park with tennis lawn or croquet ground could form a nucleus round which could be ranged the store, the company offices, the hospital, the churches, amusement hall and doctor's office. The foreman, clerks, storekeepers, time keepers, village parson, doctor and school teacher could have houses facing on such another center and their efforts at aesthetic gardening and tree planting would probably result in the duplication of their efforts elsewhere. In this way, children of like tastes would have a chance to play together in the gardens in front, having no temptations to stray on to the road and the railroad.

Curvature Often Cheaper Than Straight Lines

One ill kept house often spoils a whole row and it is not right that any man's effort at decency should be spoiled by his neighbor's proneness to disorder.

The attempt to give a lively appearance to a town by a mixing of houses of different plan and color fails to give the excellence of appearance which naturally results from an irregularity of plan. Of course some straight streets may be necessary for through travel and the topography may favor such rectilineal alignment but more often careful planning will receive its award in making grades and cost of building less than they would otherwise be. On a plot of ground sloping evenly, with every contour looking as if it were drawn by a straight edge the rectilinear plan has some advantages but where little ravines cut the ground into irregular contours there may be a big saving in land should a plan less stiff in appearance be adopted.

As Replotted by Garden City Association

Gardening

It may be objected that the plan cuts off the garden plots and makes the keeping of cows difficult. They can be provided for on the straight streets. It has been my experience that English speaking miners in company villages do but little gardening. I believe that this is due less to the fact that they do not want to make gardens than to the thieving propensities of their foreign neighbors. American labor is largely drawn from the farms; British labor takes naturally to gardening especially floriculture but there is little evidence of a love of gardening among either of these people in American mining towns. So the need for such garden plots is not apparent.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Representatives of the American Mining Congress, including the secretary, James A. Callbreath, appeared before the Senate Committee on Interstate Commerce, Feb. 2, for the purpose of urging the amendment of the Sherman act in such a way as to permit coal operators to unite in the establishment of trade agreements that would allow the fixing of rates and the regulation of output, subject to such control as the government may see fit to impose. It was stated that at present the bituminous industry is in an exceedingly depressed condition. The mines are idle about one-third of the year, and as about 500,000 men are engaged in the industry, the loss is manifestly great.

It was argued that at present the railroads are getting a large share of the price for coal paid by the consumer, and there is urgent need that the coal operators be permitted to unite in agreements for the establishment of satisfactory conditions in the business. By so doing, it was alleged, there would be a saving of money to the public at large, because unnecessary production would be stopped and thus the coal supply would be conserved, thereby rendering prices more stable over long periods.

Tables were submitted to show the actual condition of the industry. The witnesses depended largely upon the figures submitted by the Pittsburg Coal Operators' Association, in cases now pending before the Interstate Commerce Commission that are designed to test the equitableness of the rates between Pittsburg operating points and lake ports. The demands made by the representatives of the mining congress are similar to those made heretofore by other groups of coal operators.

Government Railroad for Alaska

President Taft, in a message read in the House on Feb. 1, recommends the appointment of a commission, including two army engineers, to report on the feasibility of building a government railroad in Alaska, and also upon the character of the Matanuska coal fields. The President recommends the adoption of the leasing system for government coal lands.

The message, after reviewing some of the relative advantages of the Bering River and Matanuska coal fields, favors the purchase by the government of the existing Alaska Central R.R. and its extension to the Matanuska field, as a most effective means of opening up a large and valuable portion of the territory. In conclusion the President says: "I am not in favor of government ownership where the same certainty and efficiency of service can be had by private enterprise, but I think the conditions presented in Alaska are of such a character as to warrant the government, for the purpose of encouraging the development of that vast and remarkable territory, to build and own a trunk-line railroad, which it can lease on terms which may be varied and changed to meet the growing prosperity and development of the territory. There is nothing in the history of the United States which affords such just reason for criticism as the failure of the federal government to extend the benefit of its fostering care to the Territory of Alaska.

Coal Rates at the Panama Canal

Prof. Emery R. Johnson, of the University of Pennsylvania, spent two days recently before the interstate commerce committee of the House of Representatives, explaining the bearing of the cost of coal in the United States upon traffic through the Panama Canal. Mr. Johnson said that he considered the coal question fully as important as the question of tolls in determining the distribution of traffic, making it essential to note the relative advantages of the Panama route, as compared with the Suez route, for the purpose of coaling. He called attention to the fact that when freight rates are high, bunker space on shipboard is exceedingly valuable, and rather than start with a great quantity of coal on board and freight capacity correspondingly reduced, owners will often take on coal later at a higher price.

This consideration means that there would be secured a great advantage in attracting freight, should we be able to supply coal cheaply and in an easily available way for vessels passing through the canal.

Mr. Johnson further said that the price of coal at the end of a ship's tackle at the Panama Canal today was about $3.80. He thought a dollar ought to be added for depreciation of coal while in storage and the cost of transportation through the canal to the western end. This would make $4.80. On the Suez Canal, last year's rates ran from $5.10 to $5.35. He concluded that coal rates could be so arranged as to direct traffic toward the Panama Canal.

Alabama

Birmingham—The state examinations for first- and second-class mine foremen and firebosses closed Jan. 26. C. H. Nesbit, chairman of the board of examiners, has made public the list of successful applicants. Twenty-two will receive certificates as first-class mine foremen; 6 as second-class foremen, and 28 as firebosses.

Birmingham has been recognized by the various railroads as an operating base for freight rates to northern Pacific Coast terminals. The new schedule of tariffs that will go into effect Mar. 11, makes sweeping reductions, and will place Birmingham on an equal shipping basis with all Mississippi River points, including Cincinnati and Memphis.

Colorado

Denver—The Union Pacific Coal Co. has filed proceedings in the district court to compel the secretary of state to extend its corporate existence. On Jan. 4, the coal company alleges, it attempted to file the usual certificate of renewal, and a second tender of the certificate and the necessary fee is said to have been made later. In both instances the secretary of state is declared to have refused to take action. The assets of the concern are shown as $616,500.

A strenuous battle between corporations and organized labor is reported to be on in the Trinidad and Walsenburg coal fields. On one side is found the Colorado Fuel & Iron Co., the Victor-American Fuel Co., the Rocky Mountain Fuel Co., and their various allied concerns; on the other is the United Mine Workers of America. Both sides are powerful and determined. The miners say they are going to organize the entire southern Colorado field. The corporations are just as determined that the men shall not join the unions, and are already financing their campaign of resistance. The Colorado Fuel & Iron Co. is said to have tacked on an additional appropriation of $20,000 for guards alone for the year 1912.

Illinois

Danville—Eight men are reported to have been injured, four seriously, by the falling of a mine cage carrying men going to work in the Electric coal mine, six miles west of Danville, on the morning of Jan. 31. The cage dropped a distance of about 200 ft. It was stated by

the mine owners that the engineer lost control of the machinery, causing one cage to drop to the bottom of the shaft, and the other, coming up empty, to be thrown from the mouth of the mine.

Girard—It is claimed that on Jan. 25 the mine of the Girard Collieries Co. broke the state hoisting record for mines having one-ton cars by raising 1827 tons of coal in an eight-hour run.

Springfield—The Citizens Coal & Mining Co. has just closed a contract for the entire output of Mine "B," which will amount to over one million dollars. This is one of the largest contracts ever let to any coal company in Sangamon County. It is made for four years with the privilege of extending it to cover six years.

Chicago—Advances proposed by the Chicago and Alton, and other railroads, of the freight rates on soft coal from Illinois mines to destinations in Missouri were suspended by the Interstate Commerce Commission from Feb. 2 to June 1, 1912. The proposed increases amounted to about 8 per cent. The matter will be investigated by the commission.

Indiana

Sullivan—Acting on a petition filed by one hundred employees of the Reliance Coal Products Co. which operates the Rood mine, east of Farmersburg, Joseph T. Akins has been appointed receiver for the company. All the miners have filed mechanics' liens against the concern. This is the third time the court has appointed a receiver for this company, which formerly operated under the name of the Hudson Coal and Mining Co.

Indianapolis—The Chicago and Wabash Valley R.R. Co. plans to make extensions to give it an air-line route from the Gary steel mills to the Indiana coal fields. At present the northern terminus of the line is 16 miles southwest of Gary, and the road has a length of 60 miles, reaching to McCoysburg.

The convention of the United Mine Workers of America adjourned Feb. 2 after adopting a policy to be followed in negotiating their wage scales and after selecting Indianapolis as the place for holding the next convention in 1914.

Kentucky

Pikeville—The Chesapeake & Ohio R.R. depot and the coal tipple, incline and other property belonging to the Marrowbone Coal & Coke Co. with main office at Uniontown, Penn., were burned Jan. 22. The loss was $15,000 in excess of the insurance. The fire is supposed to have been the work of incendiaries.

Henderson—M. V. Denton, who purchased the coal mining property and coal rights of the Southern Coal & Transportation Co. at Robards, has transferred the property to the Panama Coal & Coke Co.

Jess Strawlings, of Birmingham, and other Alabama capitalists have formed a corporation for the purpose of buying the Drury mines at Waverly and other Kentucky mining properties.

Louisville—The May Investing Co., of New York, which recently took over the 15,000 acres of coal land in Magoffin county, belonging to T. A. Spalding, is preparing to exploit this property. The sum paid was $480,000 and, while this seems large, it is in keeping with other prices being paid for similar investments in eastern Kentucky.

Minnesota

Duluth—Northwestern railroads, anticipating the possibility of labor trouble in the spring, are hoarding steam coal. The docks controlled by the various railroads entering this district are being piled high with the commodity and coal is arriving daily. Illinois coal supplies are being drawn upon, and it is predicted that the supply of railroad coal at the head of the lakes will have increased to immense proportions before April 1. It is also predicted that the commercial supply will be greatly lessened by spring.

The work of appraising the value of the mechanical apparatus at the old Philadelphia & Reading dock on St. Louis bay which has been taken over by the White Oak Coal Co., of Minneapolis, is being carried forward. The rebuilding of portions of the structure will not begin until the value of the plant has been ascertained.

Ohio

Bridgeport—It is understood that the Provident Coal Co., operating the big shaft mine at St. Clairsville, will start a new opening in the near future at Fairpoint, several miles from its present mine. The details of the plans are not yet made public, but it is certain that at least 300 men will be employed when the mine is in full operation.

Canal Dover—Surveyors employed by the Pennsylvania R.R. Co. are at work on a proposed extension of the Cleveland & Marietta branch of that railroad. The line will aid in developing a large tract of Ohio coal land.

Coshocton—Arrangements have been completed for the opening of the cannel coal field between Warsaw and Tunnel Hill, Coshocton County. Offices will be opened in Coshocton by the New York company that is developing the property. The syndicate controls something over 1500 acres of coal land in that territory.

Columbus—Early spring will see the beginning of extensive improvements by the Hocking Valley and Norfolk & Western Rys. in the way of increased yard facilities at Columbus. The plans of the former company include new tracks and shops. Deeds have lately been filed by the Norfolk & Western, covering ground that will be used for coal-storage yards. The cost of these improvements will run into the millions.

Rumors of the $30,000,000 merger of eastern Ohio coal companies have been revived, and plans are expected to be perfected within 90 days. There has been a renewal of negotiations recently and the companies included in the proposed deal have put a force of engineers and experts to work checking up their coal deposits to find out how much land is undeveloped.

Pennsylvania

Bituminous

Punxsutawney—A large deal in this section has just been completed, by the sale of the property of the Bear Run Coal & Coke Co. to the Boswell Coal Co., of Baltimore, Md. The price paid was not made public. The chief stockholders in the selling company were J. B. Phelen, H. G. Bowers and W. A. Bowers, of Punxsutawney; M. Burns, of Brisbin, and T. R. Johns, of Claridge, Penn. The property is situated at Sidney, Indiana County, on the Bellwood division of the Pennsylvania R.R., and is partially developed, two mines being opened. There are 3000 acres in the tract. The Boswell company is a large producer in the Pocahontas region. It is said the company intends to greatly enlarge the operations at Sidney.

Monongahela—The Acme mine of the Pittsburg & Westmoreland Coal Co., at Bentleyville, was closed down, Jan. 27, following differences between the management and the workmen, which culminated in a strike. The miners were paid in full and the plant closed.

West Newton—After two months of idleness, the West Newton shaft mines of the Pittsburg Coal Co. have resumed operation. Other mines which have received orders to resume work are the Waverly at Smithton, and the Summers No. 4 at Pricedale.

Uniontown—By a deal closed recently, the Superba Coal Co., at Beeson, and the Smith Coal Co., at Evans, have been merged. The merger means an increase in the output of coal which is all taken by the Baltimore & Ohio R.R. as locomotive fuel. The two companies now control about 1050 acres of coal land.

Yukon—The large electric generator at the Yukon mine of the Westmoreland Coal Co. burned out, Jan. 31, and closed down the mine, throwing about 600 men temporarily out of employment.

Waynesburg—L. T. Laidley and Eli F. Baily, of Carmichaels, have secured options on a block of about 1500 acres of coal in Cumberland township, near Carmichaels, at $600 an acre. The options

run for 30 days and it is believed a sale will result.

Charleroi—Nine days that the Monongahela River was frozen over in the upper pools, cut down the river coal trade in January to less than two-thirds the average. The month's shipments amounted to 9,881,000 bu., which is about 6,000,000 bu. below the average.

Pittsburg—Reports from various railroad centers state that the big lines are storing coal in anticipation of labor troubles in the spring. At all the large storing yards on the roads cars of coal are daily being unloaded and the amount held in storage in this manner has almost doubled in the past two weeks. The local roads also are taking precautions. The Pennsylvania, it is stated, has been storing coal for some weeks.

ANTHRACITE

Scranton—It is reported that prospectors have uncovered a vein of coal about four miles west of Laporte, in Sullivan County, and drilling operations are to be started to find out just how much coal there is. An outcropping of the seam, about 28 in. thick and getting thicker as the vein runs into the hillside, has been uncovered along Loyalsock Creek. Up to a short time ago it was not known that there was any coal in the vicinity, the nearest coal operation being ten miles away. The O'Boyle & Foy Co. have been leasing coal rights in the vicinity, and machinery is now being installed to begin boring operations.

The Pennsylvania State Mine Cave commission met in the commission's offices in Scranton, Jan. 26, for the purpose of selecting one or more attorneys to attend to the legal end of the investigation and to prepare a bill for presentation to the next session of the legislature. W. J. Richards, of Pottsville, is chairman of the commission, and George M. Davies, of Lansford, is secretary.

Pittston—Theodore Hogan of this city and James White of Wilkes-Barre, have become the owners of what has for many years been known as the Bowkley tract. In underlies that section of Upper Pittston known as Church Hill and includes the mineral rights under about sixty acres of ground. The consideration was $24,000.

August Savatino was working at the bottom of No. 2 shaft of the Erie Coal Co., Jan. 29, when a huge icicle which was clinging to one of the timbers in the cribbing broke loose and fell down the shaft. It struck Savatino on the head, and he was taken to the hospital in a dying condition.

Hazelton—The new Spring Brook washery of the Lehigh Valley Coal Co., at Yorktown, near here, has been put into operation. It is the first in this part of the coalfield to be operated entirely by electricity.

Shamokin—The strike of 700 employees at the Enterprise colliery, operated by W. L. Connell & Co., of Scranton, ended by the men returning to work. Satisfactory concessions were granted by the company.

Washington

Spokane—Part of the $500,000 improvements planned for the Tono mines in Thurston County, by the Washington Union Coal Co., of which the Harriman system is the holding company, were started recently. Erection of a rescue station, hospital and general offices was begun and as soon as these are completed numerous new dwellings for the miners will be built. A $250,000 power station is included in the list of improvements that will be made at Tono during the coming year.

Large deposits of coal of good quality have been discovered in the Olympic Mountains, and preparations for early development are underway at Olympia. M. E. Reed, of Shelton, says that there are traces of the vein covering over 2000 acres. Mr. Reed has arranged with the promoters of the scheme to open a five-foot vein.

West Virginia

Charleston—Fire of unknown origin recently destroyed the power plant of the Sunday Creek Coal Co. mine at Longacre, near here, causing a loss estimated at $60,000. In consequence, the mine has been closed down until a new power plant can be erected or power furnished from one of the other mines of the company. Work on rebuilding the plant has already been started.

One of the biggest development propositions attempted in the state for a long time is that already begun by the Pond Creek Coal Co. in Mingo County, where the company has acquired 30,000 acres of coal land. Contractors have begun work on the construction of a branch from the main line of the Norfolk & Western road. The Pond Creek Coal Co. has an authorized capital of $2,000,000, and many of its stockholders are said to be the same as those interested in the big operations at Holden, Logan County. The bridge to be constructed across Pond Creek, for which authority was recently granted by Congress, will be used by the Pond Creek company to reach the main line of the Norfolk & Western. The completion of the plans of this company will greatly increase the coal output in the Pocahontas district.

Wyoming

Rawlins—The Sampo coal mine at Hanna, with about 640 acres of coal land, was purchased recently by a Cheyenne syndicate, headed by J. D. Woodruff, the Hoffman brothers and others. The property will be developed at once.

Chronology of Coal Mining for January

Jan. 1—The Virginia Iron, Coal & Coke Co. secured a $9,000,000 contract for furnishing locomotive fuel to the Boston & Maine R.R.—A general strike of miners in Belgium was threatened, when 25,000 men in the Borinage district stopped work.—The Lehigh Valley Coal Sales Co. was incorporated in order to bring the Lehigh Valley organization into conformity with the commodities clause of the interstate commerce act.—Convict labor was abandoned at the mines of the Tennessee Coal, Iron & R.R. Co.

Jan. 4—Two shot firers were rescued from an explosion in the Girard Coal Co.'s mine, at Radley, Kan., through having telephoned their whereabouts to the surface a short time previous to the accident.

Jan. 5—Fire destroyed the shops and engine house at the drift mine of the Davis Coal & Coke Co., Thomas, W. Va. Loss, $12,000.

Jan. 7—Fire destroyed a portion of the plant of the Galloway Coal & Coke Co., Carbon Hill, Ala. Loss, $50,000.

Jan. 9—An explosion in the No. 9 slope of the Parrish colliery, at Plymouth, Penn., killed six men and seriously injured two.

Jan. 10—Gov. Tener appointed a commission to revise and codify the anthracite-mine laws of Pennsylvania.

Jan. 12—A boiler exploded at the Clarence colliery of the Hillside Coal & Iron Co., Pittston, Penn., wrecking the plant.—Six men were seriously injured by the explosion of a box of dynamite caps at the Knickerbocker colliery, Shenandoah, Penn.

Jan. 15—The United States Supreme Court rendered a decision upholding an employer's liability act as constitutional.

Jan. 16—The American Federation of Coal Operators was permanently organized at a meeting in Chicago.—The twenty-third annual convention of the United Mine Workers of America opened in Indianapolis with nearly 1400 delegates present.

Jan. 17—An explosion in a mine of the Central City Coal & Iron Co., Central City, Ky., killed five men. The day shift of 200 men had just left the mine.

Jan. 18—Delegates to the national conference of coal miners in Great Britain voted unanimously in favor of a strike, Mar. 1, unless a minimum wage scale was granted. Ballots cast by the miners were 445,801 for a strike and 115,921 against it.

Jan. 20—A dust explosion in mine No. 4 of the Kemmerer Coal Co., Kemmerer, Wyo., killed five men and injured eighteen.—An ice gorge in the Ohio River, opposite Louisville, Ky., broke and caused a loss of about $20,000 to coal boats and barges.

Personals

John A. Garcia, of the Allen & Garcia Co., consulting engineers, Chicago, was in New York for several days last week attending to some matters of business.

S. D. Warriner, vice-president and general manager of the Lehigh Valley Coal Co., Wilkes-Barre, Penn., left, Feb. 2, for a two-weeks trip to North Carolina.

E. P. Merritt, assistant to the vice-president, T. B. Davis, of the Island Creek Coal Co., is now in Williamson, W. Va., looking after the opening up of the 30,000-acre tract of coal land recently purchased by the Pond Creek Coal Co.

W. H. Cunningham, general manager, and C. R. Connor, manager of mines, of the West Kentucky Coal Co., Sturgis, Ky., have resigned their positions with the company, effective Feb. 1, and will form a business partnership as consulting and contracting engineers, with offices in Huntington, W. Va.

Col. R. A. Philips, formerly superintendent of the coal-mining department of the Delaware, Lackawanna & Western R.R., has been made general manager with headquarters at Scranton as heretofore. Charles E. Tobey, formerly assistant superintendent, has been promoted to the office of superintendent.

W. J. Houston, general sales manager for the Moreland Coke Co., in Ohio, with offices in Cleveland, has been promoted to the position of general sales manager of the Moreland company, effective Feb. 1, and will hereafter be located at Pittsburg, Penn. Mr. Houston has been in the employ of the Moreland Coke Co. for the past two years and previously was general sales agent of the Big Vein Coal Co., one of the Youghiogheny & Ohio interests.

Yes, Sir! Our old friend Everett Moore, chief engineer of the Consolidation Coal Co., Fairmont, W. Va., slipped one over on us, and is now a "lifelong member" of the Benedicts' Club. Just when we were about to pass him up as a hopeless prospect, he goes and doubles his expenses, triples his happiness and pretends that all he ever pined for was a bungalow with gas logs in the parlor. All right, Everett! Here's wishing you happiness unmeasured. May a long line of descendants add luster to your name! Now that Frank Haas has started the game and you have followed suit, we suppose the "Consolidation" will force the habit by compelling unmarried employees to contribute regularly to an orphan asylum or a spinsters' fund. However, let us say right now, that if any more of our friends try this same plan of letting us in on the secret after the "Wedding Cake" is all eaten, we'll write something about them that will read like "Why Wives Leave Home."

Obituary

W. W. Worthington, president of the Montana Coal & Iron Co., and one of the prominent coal operators in Montana, died, Jan. 30, from heart disease. His family resides in New York, where the body was sent. Mr. Worthington, who was well known throughout the Northwest, had been ill for several months.

James Collins, president and general manager of the Allburn Coal & Coke Co., of Matewan, W. Va., died at his home in Matewan, Wednesday, Jan. 31. He was born in Staffordshire, England, July 8, 1864. Mr. Collins was well known in the Pittsburg district, having been employed for a number of years by the National Mining Co.

Philip Davis, of Duquoin, Ill., a member of the executive board of the Illinois miners, died suddenly, Jan. 24, at Indianapolis, where he had gone to attend the convention of the United Mine Workers. Mr. Davis had been prominently identified with the miners' organization for a number of years and had many friends in southern Illinois.

Construction News

Punxsutawney, Penn.—The Boswell Coal Co., of Baltimore, Md., has purchased the property of the Bear Run Coal Co., in Indiana County, and intends to greatly enlarge the operations at Sidney.

Moundsville, W. Va.—Proposals for an elevator to be furnished complete at the tipple of the Panama mine will be received by the Ben Franklin Coal Co., Moundsville, W. Va. M. J. McQuade is general manager.

Birmingham, Ala.—The Pratt Consolidated Coal Co., of Birmingham, will construct facilities for coaling vessels at Mobile, Ala.

St. Clairsville, Ohio—The Big Five Coal Co. has increased its capital stock from $200,000 to $300,000 to provide for extensions and improvements at its operations. Samuel Pursglove, Sr., is president.

Columbus, Ohio—The Hocking Valley and Norfolk & Western railroads will make extensive improvements at Columbus, including storage yards, increased track facilities and shop buildings.

Spokane, Wash. — The Washington Union Coal Co., a subsidiary of the Harriman railroad interests, contemplates the erection of a $250,000 power plant at the Tono mines, Thurston County, Washington.

Recent Incorporations

Huntington, W. Va.—The Pinson Fork Coal Co., of Huntington, to mine coal and manufacture coke in Kentucky; capital, $100,000. Incorporators: A. E. Bush, E. M. Watts, I. J. Bryan and others, all of Huntington.

The Amherst Coal Co., of Red Star, W. Va., to mine and deal in coal and other minerals; capital, $50,000. Incorporators: George M. Jones and W. R. Thurmond, of Oak Hill, W. Va., and three others.

The Turkey Foot Land & Lumber Co., of Huntington, to mine coal and manufacture lumber in Jackson County, Ky.; capital, $300,000. Incorporators: C. L. Ritter, H. T. Lovett, E. E. Williams and others, all of Huntington.

Charleston, W. Va.—The Lane-Whitmer Stores, Inc., of Charleston, to mine coal and engage in a general mercantile business; capital, $500,000. Incorporators: Harry E. Moyer, L. S. Lucas and Max Stozzie, of Philadelphia, Penn., and others.

Spokane, Wash.—The Tanum Coal Co., to develop a tract of coal land on Tanum Creek, near Ellensburg, Wash.; capital, $500,000. A. N. Cantrill, of the Spokane Gas Co., is one of the incorporators.

Harrisburg, Penn.—The Keystone Coal & Coke Co.; capital, $400,000. Incorporators: Richard Coulter, Geo. F. Huff, E M. Gross, Lloyd B. Huff, Robert Pitcairn, Jr., and Robert K. Cassatt.

Pittsburg, Penn.—The Atlas Coal Co., of Pittsburg; capital, $250,000. Incorporators: G. Z. Hosack, J. A. Bell, J. B. Haines, Jr., and others.

Connellsville, Penn.—The Connellsville Coke Co., of Connellsville; capital, $33,000. Incorporators: J. Fred Kurtz, W. D. McGinnes and R. S. Matthews, Connellsville.

The Etna-Connellsville Coke Co., Connellsville; capital, $125,000. Incorporators: Cyrus Echard, G. W. Campbell and D. N. Parkhill, Connellsville.

The Superba Coal Co., of Connellsville; capital, $10,000. Incorporators: A. C. Stuckel, M. E. Brazell and J. W. Buttermore, Connellsville.

Barbourville, Ky.—The Clover Fork Coal Co., to operate mines in southeastern Kentucky; capital, $50,000. S. F. Whitfield is one of the incorporators.

Industrial Notes

The rapidly increasing demand in Pittsburg and vicinity for asbestos, magnesia and other products of the H. W. Johns-Manville Co., has necessitated a move from their former location in Liberty Ave., above Ninth St., to larger quarters. Since Jan. 24, 1912, the Pittsburg branch of the H. W. Johns-Manville Co., has, therefore, occupied the entire eight-story stone, reinforced-concrete and steel building at the northeast corner of Wood St. and First Ave., which has been leased by them for a term of years.

The McGraw-Hill Book Co. announces the completion of arrangements for the sales agency of the technical books of the Railway Age Gazette, American Engineer and Signal Engineer. This makes the McGraw-Hill Book Co. publishers and distributors of books for the three journals, but it does not affect the publication of the papers themselves in any way. With the addition of these three papers in the railroad field, the McGraw-Hill Book Co. now publishes books for the twelve leading American engineering papers in the fields of civil, mechanical and electrical engineering, electric and steam railroading, machine tools, mining, metallurgy, chemical engineering, etc. The papers now represented are American Machinist, Engineering News, Electrical World, Railway Age Gazette, Electric Railway Journal, Power, Engineering Record, Engineering and Mining Journal, Coal Age, Metallurgical and Chemical Engineering, American Engineer and Signal Engineer.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The fuel shortage continues unchanged, except possibly a further tightening of the situation, particularly in the East. Anthracite supplies are estimated to be smaller than at any time for a number of years and spot coals of all grades are commanding good prices and are eagerly sought for storage purposes. Complaints of railroad service are general, which condition is seriously affecting production at the mines.

Low temperatures in the East, causing a heavy consumption, together with the slow movement, both by rail and water, are making the situation acute at some points. Many large consumers are now anxious to store in anticipation of a possible strike Apr. 1, but are having trouble in finding any free coal.

In the Pittsburg district, bituminous is in good demand with prices hard, and coke holding firm under an unusually heavy production. An over-production of slack in the Ohio fields has caused a break in prices on this grade, although market in other sizes continues strong with the dealers in command. Poor transportation facilities are curtailing production at the mines to about 50 or 60% capacity, and, as a result, there is no spot coal to be had. The nonunion fields to the South are preparing for a heavy production in event of a shutdown at the organized mines on the expiration of the present agreement.

Prices in the Middle West are off slightly, but still above normal. Stocks are materially reduced, the movement slow and demands urgent, with only sufficient tonnage to meet the requirements for immediate consumption. Court orders have been issued governing the movement on some of the railroads and others have been compelled to confiscate fuel. The Western market remains quiet and unchanged.

Boston, Mass.

February was ushered in by three days of storm, and dealers and large consumers were caused further anxiety over slow moving cargoes. There has been no break in the seasonable weather and demand is active for coal of every kind. All over there are instances of dealers with but a few days' supply awaiting arrivals either of cars or cargoes detained by adverse weather. The situation is acute, and a partial suspension, such as that in effect at the textile mills in Lawrence, is a decided relief to some of the soft-coal shippers who have been able to supply only in a hand-to-mouth fashion.

The great difficulty in getting barges from Hampton Roads has lately diverted some tonnage to Philadelphia, and there has been a slight advance in the f.o.b. price for spot coal on that account. Coal from the Clearfield districts has been sold up to $2.60, f.o.b., and an extra demand for that grade is in prospect between now and Apr. 1.

All-rail bituminous is only changed in the way of still slower deliveries and higher prices for spot coal at the transfer points. Coal available for February has been marked up by practically all the shippers.

The supplies of anthracite in New England seem to be further and further reduced. With the storage depots maintained here at tidewater by certain of the mining companies, bare of all sizes, an increased demand is thrown on the companies that ship all-rail, a demand which the latter are unable to meet.

Current prices are as follows:

Clearfield, f.o.b. mines	$1.25@1.45
Somersets, f.o.b. mines	1.35@1.55
Pocahontas, New River, Boston, on cars	4.35@4.60
Pocahontas, New River, Providence, on cars	4.25@4.50
The same coals, for shipment, f.o.b. Hampton Roads	2.70@2.75

New York

The stocks of soft coal on hand at the New York piers are considerably below normal. Shippers are still complaining of poor car supply and of slow railroad movement. These conditions coupled with a heavy demand on contract business, tend to keep the supply here low. There is a strong demand for the better grades of steam coal, but these are scarce and purchasers of coal are obliged to substitute the cheaper grades because of the scarcity of standard steam coals.

Prices show some advance from last week, West Virginia steam coals being firm at $2.60 f.o.b., while the ordinary grades of Pennsylvanias are being held at from $2.65 to $2.70, with the standard steam coals practically out of the market.

Congestion and accumulation of freight along the railroads are retarding the delivery of coal to line consumers and causing them much uneasiness as to their supply. This has caused a sharp increase in the demand for all-rail coal. Consumers generally are endeavoring to accumulate stocks in anticipation of labor troubles in the mining regions the first of April, but are finding their supplies gradually decreasing, instead of increasing.

The winter weather so far experienced has been much more severe than any for a number of years and has not only affected transportation, but has undoubtedly caused a marked increase in consumption which should keep the market on a firm basis for some time to come.

Marine transportation in the harbor and sound is made hazardous by the ice conditions. At the piers, while not so much difficulty is being experienced in the handling of frozen coal as during the preceding two weks, there is still delay of from two to three days in loading. Under these conditions the coal shippers are experiencing great difficulty in taking care of their business.

Philadelphia, Penn.

The beginning of the week witnessed another snow flurry, with a low temperature, and, as a consequence, dealers are beseiged with requests for urgent filling of orders, and additional ones are piling up. The anthracite trade at this point could not be improved upon, as all the tonnage coming in is being taken care of, and the additional cold snap only adds discomfort to an already unpleasant condition.

The reflection of the retail trade is seen in the wholesale. The tonnage for the month of January was considerably in excess of the previous year for the corresponding period, and the operators are already planning for a successful February. Comparisons so far this month indicate that the month of February will also prove to be a better coal-burning month than the same time last year—at least the tonnage will move off, which is all that is required. All sizes still continue in demand, and it is understood that some of the companies are turning down orders for some of the large sizes, it being impossible to supply the market, as well as the quantity required for contracts.

The bituminous market shows some improvement, prices being somewhat stiffer, due in part to the fact that there is restricted mining on account of the weather, and poor movement along the railroads. There is also a slight shortage of cars, all of which has a tendency to stiffen the market on this grade of coal.

Pittsburg, Penn.

Bituminous—The annual convention of the United Mine Workers, at Indianapolis, adjourned, with no scale settlement being reached. While negotiations will still be conducted with the operators, there is practically no prospect of any agreement being reached before the termination of the scale, Mar. 31, and a suspension of mining for six weeks or so is likely before an agreement will be attained. While consumers have not begun stocking up yet on a liberal scale, there is a disposition in this direction, and odd lots offered in the market find ready acceptance, making prices steadier than for a long time.

Demand for domestic coal continues excellent, on account of the cold weather. We quote: Nut, \$1.05@1.10; mine-run, \$1.10@1.15; ¾-in., \$1.20@1.25; 1¼-in., \$1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg district.

Connellsville Coke—The market for prompt furnace coke has eased off a trifle, being quotable at \$1.80 to \$1.90, against \$1.85 to \$2 a week ago. This is due to heavier production, but the market has not weakened as much as would have been expected, with production running, as reported, at fully 400,000 tons a week. Sales of prompt furnace coke within this range have been made in the past week to the extent of 150 to 175 carloads. No further contracting is reported. Furnaces are well covered, unless it is necessary to blow in additional stacks. Foundry coke has stiffened, on account of scarcity, and there has even been buying of small lots by producers. We quote: Prompt furnace, \$1.80@1.90; contract furnace, \$1.80@1.90; prompt foundry, \$2.15@2.25; contract foundry, \$2.20@2.40.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Jan. 27, at 400,597 tons, a decrease of 6000 tons, and shipments of 4220 cars to Pittsburg, 5829 cars to points West and 1064 cars to points East, a total of 11,113 cars, a decrease of 158 cars.

Baltimore, Md.

Heavy buying on the part of a large number of consumers, for stocking-up purposes, was the feature of the Baltimore market during the last week. Fear of a possible strike has caused many to reach the conclusion that it would be wise to look ahead, and some have been purchasing freely during the last few days. The large operators here predict that this rather heavy buying on the part of far-sighted consumers will continue for several weeks, or until they are reasonably sure that the operators and their employers will reach some satisfactory agreement.

The activity in the market caused prices of all grades of coal to remain firm. The low grades, according to figures obtained at several offices, are still being quoted from 80c. to \$1. Better grades can be purchased from \$1.05 to \$1.20, while big vein coal is quoted from \$1.30 to \$1.60.

At the port of Baltimore, congested conditions are no longer encountered. While there is considerable ice in the river and bay, it is not proving the hindrance to shipping operations that it did during the zero spell of weather.

Buffalo, N. Y.

There is a good demand for bituminous coal, and it appears to increase from week to week. Prices are firm, but there is little prospect of an advance. The real advantage gained over the early part of the winter is that little or no coal is selling at a sacrifice or at the terms of the consumer. In fact, the rail movements are so slow that the seller is much more in command of the situation than for some time, and keen competition is the only thing preventing an immediate advance. Dealers, however, find that they cannot safely advance their prices, as buyers usually know where to find a supply at the old prices.

There is much complaint against some of the railroads, for allowing their business to become so badly congested. The New York Central and Nickel Plate roads are especially slow in their movements and some very aggravated cases of delay are in evidence.

Bituminous prices are strong at former figures, \$2.50 for Pittsburg three-quarter, \$2.40 for mine-run and \$2.25 for slack, with coke doing better than formerly, at \$4.25 for best Connellsville foundry and \$3.50 for stock coke. Allegheny Valley prices are about 25c. lower than Pittsburg.

The anthracite situation remains unchanged, with every ton of coal that the shippers can get going at once into consumers' hands.

It is predicted that there will be a greater shortage of anthracite at the opening of spring than has ever been seen before in the trade. It is common to put a large amount of it afloat here in readiness for the opening of the lakes, but none is to be had for such purposes yet. Soft-coal dealers who can get independent anthracite readily, can sell it at a premium if they choose.

Cleveland, Ohio

The weather in the last week has been much milder, and railroads have given better service in handling coal to the markets. Domestic lump has had a good demand, with prices firm. There is a decided demand for steam grades in mine-run and ¾-in., particularly mine-run; slack has been somewhat of a drug in the market for a week, prices in consequence dropping 10 to 15c. Every available car of slack that could be secured was rushed to this market when the railroads got busy after the snow blockades, which resulted in prices breaking, as it could not be handled in time to save car demurrage. However, the situation at this moment is somewhat relieved, and the general impression is that slack will again become scarce in the next week or ten days.

Columbus, Ohio

Continued low temperatures, coupled with the congestion on all initial and connecting railroads, has had the effect of keeping the coal trade in Ohio firm during the last week. Considerable demoralization is reported on all lines, and the lack of motive power is the chief obstacle to a better movement. Thousands of loaded cars are sidetracked on all lines, and the danger of a coal famine in certain sections is growing worse.

The cold weather has shown that not one of the railroad lines has been equipped to handle traffic in a time of stress. The fault has been both with the initial lines and the connecting roads, but the latter are probably more at fault than the former.

Prices have remained steady at the circular figure, and every branch of the trade is firm. Fine coal is a little weaker, but the recession in price was only slight. The demand for steam grades is good, as there is a disposition on the part of certain large users to store, in anticipation of a suspension after Apr. 1. Some of the railroad lines have stored a large amount of fuel in case of emergency. Retailers are clamoring for shipments, and in many cases their customers are inconvenienced. No great actual suffering has been reported in central Ohio, as yet.

Operations at the mines have been irregular, some reporting from 50 to 65% capacity, while others have been fortunate enough to show a larger production. Inability to secure cars and congestion on the roads are the causes of this decreased production. Practically every mining district of the state is affected by these conditions, but the greatest loss is in the eastern Ohio district.

Reports show that there are between 4000 and 5000 loaded coal cars at Toledo waiting movement to Michigan and northern Indiana points. There is great danger of a coal famine in Detroit, and frantic efforts are being made to remedy that condition.

Prices prevailing in Ohio are as follows:

Domestic lump in Pomeroy Bend district	\$1.65@1.75
Domestic lump in the Hocking Valley	1.50
Three-quarter inch	1.35
Nut	1.15
Mine-run in eastern Ohio	1.00@1.05
Mine-run in the Hocking Valley	1.05@1.15
Nut, pea and slack	0.75@0.85
Coarse slack	0.65@0.75

Charleston, W. Va.

January has been one of the poorest months in production that this state has had for a long period. The weather conditions were such as to close, for a time, some of the mines and, when they were able to resume, the car supply was inadequate and this still continues in the Chesapeake & Ohio region, the mines working on an average of only one or two days a week. Other sections of the state are reported almost as bad. As a result the output for January will be lower than it was in January, 1911, one of the lowest months for many years, and unless the car supply soon resumes normal conditions February will be found in the same class

The car shortage, however, has had a tendency to increase prices except, of course, on contracts. Kanawha district slack has gone up to, in some instances, as high as 85c., while lump from the same district is bringing $1.50@1.60. New River mine-run is about the same as in the Kanawha district, but New River egg is bringing as much as $1.80.

Even with an early spell of warm weather it will take a considerable time before loaded cars can be sent to their destination, the empties returned to the mines and a normal condition on the rails and at the mines restored.

Louisville, Ky.

The variable weather of this winter is keeping up the brisk demand for fuel, which has made the present season one of the best, from a dealer's standpoint, for years. The retailers, however, have lived up to promises made earlier in the winter that, except in case of extraordinary conditions, the price of coal should not be boosted to unreasonable and exorbitant figures. One effect of the severe weather will be that reductions in price, which usually accompany the approach of spring, will be delayed longer than usual. Much suffering among the poorer classes has occurred, due to the low temperatures.

Owners of factories, and agents for office and store buildings, have experienced much trouble in providing sufficient motive power and heat, respectively. Relays of firemen and furnace feeders have been kept on duty constantly in many instances.

The demand for nut and slack continues to be unprecedented, due to the requirements of the steam-heating plants. The quotations by retailers continue to range as follows: Banner lump, $3.25; Jellico, $3.60; Wilton-Jellico, $3.60; Pittsburg, $3.75; Taylor, $3.25.

Nashville, Tenn.

Business continues to be excellent, although the mines here are handicapped by an insufficient supply of cars, which makes it hard for them to keep up with their orders. Prices are unchanged and the demand good. Screenings are still bringing a good price and are in big demand.

Every indication points to the west Kentucky nonunion field being extremely busy this spring provided there is a shutdown throughout the union fields of the country. St. Louis will draw very heavily from this field and the operators here are anxiously awaiting the time. The privilege of shipping coal at a good price North every two years is a welcome one.

So far there has been no demand for coal for storage purposes from this field as what little coal is being stocked is being taken from lines adjacent to the territory to which it is used, at a much cheaper freight rate. Should we have a late spring with plenty of cold weather, the chances are that the west Kentucky field will be called upon for storage coal during the month of March.

Indianapolis

Indiana coal operators report business good, due to continued cold weather. The low temperature during the entire month of January thoroughly frightened the people of the country, who were unprepared for it, and the result is that they are preparing to secure themselves against further suffering this winter.

Nearly all the mines of the state are working almost steadily, or as many days as are possible with the present car shortage. The railroads appear utterly unable to handle the business, the trouble being with the bad condition of their rolling stock. The retrenchment policy, instigated by a number of roads over a year ago, is now causing them to lose business amounting to ten times the cost of keeping the cars and locomotives in good serviceable condition. Among these railroads are great lines of coal cars out of condition and unfit for use, while the repair shops are full of engines awaiting repairs to make them serviceable. In Brazil, Terre Haute and other coal centers, all the tracks of the coal roads are full of crippled cars and locomotives.

Chicago

While prices in the Chicago market continue to decline, they are still far above a normal condition. The chief factor in the situation is the car supply. A combined movement of some delayed coal and of all that more recently shipped is caring for the current demand—and that is all. It is not expected that the market will become very soft until stocks can be replenished and old orders filled. Another cold wave also is having a strengthening effect.

Smokeless coal is variable in price, but in strong demand. What little there is of spot smokeless coal commands a price of $1.25 to $1.40 for mine-run. On shipments direct from the mines, prices range from $1.10 to $1.25. Hocking maintains a strong position. The market for screenings has been exceptionally satisfactory to dealers, holding firm at $1 to $1.10 for small-size screenings and $1.10 to $1.25 for the 2-in. variety. The anthracite market is still tight.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.62@2.87
Steam lump	2.22@2.37
Screenings	1.97@2.07
Springfield:	
Domestic lump	$2.57@2.67
Steam lump	2.17@2.27
Mine-run	2.07@2.17
Screenings	1.77@1.92
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.22@2.32
Mine-run	2.17@2.27
Screenings	1.77@1.92
Pocahontas and New River:	
Mine-run	$3.15@3.30
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.50@4.65; byproduct, egg and stove, $4.85; byproduct, nut, $4.55@4.65; gas house, $4.90@5.

Minneapolis—St. Paul

The retail trade in the Twin Cities report a favorable week even though business has not been extremely rushing, which has given them time to catch up on orders taken in. Both in Minneapolis and St. Paul the retailers' stocks have been reduced materially and they are experiencing troubles in getting cars when they want them. However, a shortage in the Twin Cities is not probable, due to the short haul from the docks, unless the severe cold weather of January should be duplicated.

Wholesalers report business good in the country, but are complaining of the car shortage and of the railroads confiscating coal for their own use. Prices on all grades are selling for circular or better and some big premiums are offered for coal in transit nearby. Steam plants are asking for quotations and their buying from now on will be a factor until the strike situation is definitely settled.

Another feature of cognizance is that the railroads are buying and storing considerable coal—fearing a possible shutdown at the mines. Railroads operating in the Northwest are taking no risks of a car shortage and are not letting their cars off the initial road, except under extreme necessity.

St. Louis, Mo.

Following the snow storm of last Saturday came a cold snap similar to that in January, and with the poor motive power on the railroads, spot coal at East St. Louis commanded almost anything the shipper asked. Carterville lump and egg

opened strong, and there was but little to be had as the railroads are taking practically all of the available coal from that field. As reported previously, this is not done openly, but, nevertheless, the railroad companies are storing in large quantities, and nearly every mine in the Carterville field is being pushed for railroad coal.

The washers in the Carterville field were again put out of commission on account of the cold weather, but raw coal is bringing such a price now that it pays the operator better to omit the washing.

The Standard market has been in a somewhat unsettled condition during the past week, jumping from $1.15 last Saturday morning to $1.50 before noon, and it opened strong Monday, with everything to indicate that the Standard operators will be able to keep the market up.

The only operators in the Standard field that are getting any service from the railroads are the mines at St. Clair and Wildermann, where the operators have a court order, compelling the Illinois Central to give them cars every day that they are available, regardless of whether other mines get cars or not. The market on the inner district high-grade coals is in good condition, the demand exceeding the supply. A large tonnage of this coal is moving into the Northwest.

The anthracite movement in St. Louis has been fairly good, considering the poor service of the railroads. Coke is in good demand at $5 for byproduct and $4.75 for gas house.

The past week opened up with the following prevailing prices:

Franklin County	
Lump and egg	$2.00@2.25
No. 1 nut	2.00@2.25
No. 2 nut	1.85@2.00
No. 3 nut	1.25@1.40
2-in. screenings	0.90@1.00
Carterville	
Lump and egg	$2.00@2.25
No. 1 nut	1.85@2.00
No. 2 nut	1.50@1.60
No. 3 nut	1.25@1.40
Screenings	0.80@0.95
Mine-run	1.15@1.25
Standard	
6-in. lump	$1.75@1.85
2-in. lump	1.50@1.60
3x6-in. egg	1.25@1.40
No. 1 nut	1.00@1.10
No. 2 nut	0.90@1.00
Screenings	0.80@0.90
Mt. Olive	
6-in. lump	$1.50@1.60
3-in. lump	1.50
3x6-in. egg	1.35
No. 1 nut	1.10
No. 2 nut	1.00

Spokane, Wash.

The weather in the Inland Empire has moderated to such an extent that little coal is being used in the residence districts, other than just enough to keep the chill off of the interior. The sales from the local yards have decreased materially and the supply is slowly being replenished to prepare the dealers in case of emergency.

The prices have not changed for some time in the better grades. However, some of the cheaper coals have decreased slightly to increase the demand.

The standard values continue as follows:

	Wholesale	Retail
Rock Springs	$7.20	$9.00
Owl Creek	7.20	9.00
Kirby	7.20	9.00
Carney	6.70	8.50
Bearcreek	6.35	8.25
Roslyn steam	5.25	6.25

Portland, Ore.

The situation as to the demand for fuel in this state remains unchanged since last week, the weather continuing mild. This has been a mild winter, and the demand for coal has been light.

Business in general is fair and showing signs of improvement. There is a good deal of activity in the building line here, with every indication of a very busy season the coming summer. The forthcoming completion of the Panama Canal, everybody predicts, is going to cause a wonderful activity on this coast in all lines of commerce, and a very heavy coastwise movement is anticipated. A number of vessels are now being built in Pacific Coast yards to ply between ports on the Pacific and the Atlantic. If vessels can be engaged to bring coal here from the Atlantic Coast at considerably lower prices than are charged now, it should create a new and active demand for that class of fuel, as wood prices are high enough to admit of competition, in spite of the fact that Oregon produces immense quantities of lumber. At present Australian coal is quoted at $10. Domestic coal may be had as low as $6.50, but it does not enter very heavily into competition with Wyoming or Australian coal.

Production and Transportation Statistics

Imports and Exports

The following is a comparative statement of coal and coke imports and exports from the United States for the years 1910-11, in long tons:

EXPORTS	1910	1911
Anthracite:		
Canada	2,963,788	3,498,980
Other countries	57,839	55,019
Total	3,021,627	3,553,999
Bituminous:		
Canada	7,567,297	10,609,587
Panama	......	496,830
Mexcio	675,980	470,674
Cuba	858,776	1,053,703
West Indies	487,519	577,159
Other countries	1,194,667	670,801
	10,784,239	13,878,754
Coke	879,123	914,142
IMPORTS		
Anthracite	......	2,159
Bituminous:		
United Kingdom	13,124	9,278
Canada	1,675,692	980,174
Japan	56,278	16,031
Australia and Tasmania	240,899	232,969
Other countries	5,950	356
Total	1,991,943	1,238,808
Coke	156.417	69.515

Great Northern Ry.

Great Northern's coal movement from Duluth to Minneapolis and St. Paul in January totalled 5137 cars, breaking all records. Consumptive coal demand is heaviest on record in Northwest on account of continued cold weather.

Foreign Markets

Great Britain

Stemming is becoming increasingly difficult for February positions, and prices are firm. The outlook in regard to the labor situation is a little more hopeful. Quotations are approximately as follows:

Best Welsh steam coal	$4.68@4.80
Seconds	4.50@4.62
Thirds	4.20@4.44
Best dry coals	4.26@4.38
Best Monmouthshire	4.20@4.26
Seconds	3.96@4.02
Best Cardiff small coal	2.52@2.64
Seconds	2.34@2.46

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½% discount.

Financial Notes

The Fairmount Coal & Coke Co., of Pennsylvania, has announced that its coupon 34, due Dec. 1, 1906, on the first mortgage bonds, will be paid on presentation to the Farmers' Loan & Trust Co.

After charging operating expenses of the Railway and the Coal & Iron Co. with renewal expenditures, Reading Co. earned $4,480,688 after charges in the six months to Dec. 31, as against $4,029,076 a year ago. Deducting preferred dividends there remains for the $70,000,000 common stock a balance of $3,080,688, or 4.4% in contrast with $2,629,076, or 3.7% last year.

Solvay Process Co., Syracuse, N. Y., on Jan. 31, filed a certificate increasing the capital stock from $10,000,000 to $15,000,000, the new shares to be distributed as a stock dividend of 50%. Secretary George E. Francis is quoted as saying that the increase is made in order to place the capital stock on a basis proportionate to the volume of business done by the company.

The Delaware, Lackawanna & Western Coal Co. reports for year ended Dec. 31 last:

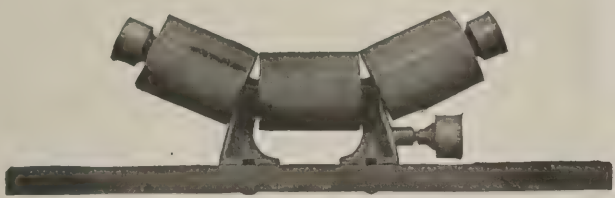
	1911	Increase
Coal sales	$39,865,493	$1,197,243
Expenses	38,235,111	1,000,114
Net income	1,630,382	197,129
Other income	165,278	55,915
Total income	1,795,660	253,043
Dividends	659,070	....
Surplus	1,136,590	253,043

The profit and loss surplus on Dec. 31 was $2,513,120.

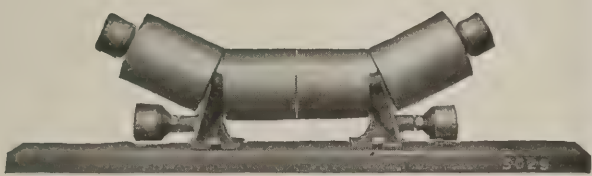
At Boston, on Feb. 2, Judge Dodge in the United States District Court appointed John T. Burnett, of Southboro, Mass., as receiver of the Rhode Island Coal Co. on application by H. M. Whitney, who stated that the company was without working capital or borrowing capacity. The following reorganization committee has been nominated: Charles B. Jopp, president, Beacon Trust Co.; Edward Page, vice-president Federal Coal & Coke Co.; Herbert A. Tucker, of Tucker, Hayes & Co.

"Link-Belt" Belt Conveyors

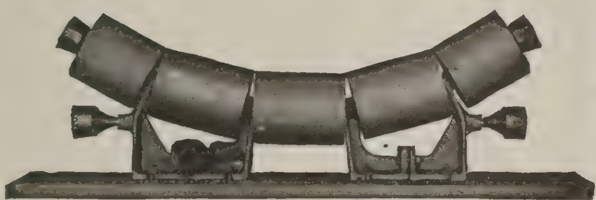
We have manufactured and installed Belt Conveyors for purposes for which they were suitable for upwards of 20 years and are furnishing the most efficient and durable equipment to-day.



Standard 3-Pulley Idler. (Patents Pending)

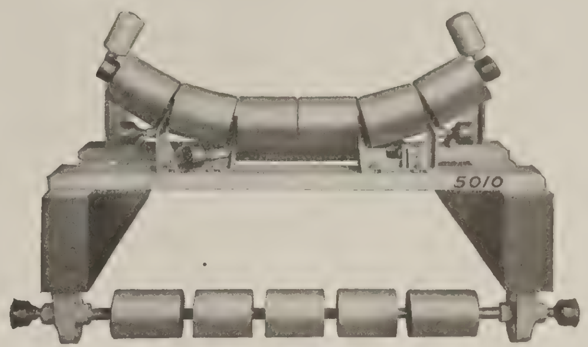


3-Pulley Idler. (Patents Pending)



Standard 5-Pulley Idler (Patents Pending)

"Link-Belt" Conveyor handling coal in power house.



48-in. Idler with Guide and Return Rolls. (Patents Pending)

COAL AGE

Vol. 1 NEW YORK, FEBRUARY 17, 1912 No. 19

WHERE DO WE STAND?

That's the question some are now asking us and we concede their right to know. Every advance, industrial or moral, must have its champions, and those who entrust themselves to such leadership want to know where they are going and the reason therefor.

All our promises and declarations were made before the birth of this journal, nineteen weeks ago. With the first issue, we quit talking and commenced "sawing wood," and since then have published 630 pages of the best coal literature it was possible to secure. During this time, we have studiously avoided the use of our reading pages for self-advertisement, believing that "making good" is a matter of deeds, not talk. All our time has been devoted to building a paper that would be worthy and representative of the great industry we serve.

To the few competitors who wished us ill, we extend greetings, and desire to say that our refraining from retort was through lack of sufficient cause and not from any overwhelming desire to avoid controversy. There's no use in bothering when the missiles intended for you are hurled straight up in the air. You can always feel sure, in such a case, that if one of the bombs doesn't come down and blow your adversary's head off, bad manipulation of his artillery will cause an explosion, the result of which will be equally fatal to him.

You can stand at the foot of a mountain, look up, and shout that the ground before you is level, but you'll climb all right before you get to the top. Those who are proclaiming that Coal Age is a paper for managers only, or for miners only; for theorists or for practicalists; for anthracite, or for bituminous men, do not interest us in their outcry. Any success they win through misrepresentation is temporary. We're building a journal for all, and expect it to last a thousand years, not one or two. Our conception is that we've a life's job before us; a serious, responsible task, which can result in great good or great harm to the multitude of workers we represent.

We have a clear idea of what we propose to accomplish, and entertain no fear of human coyotes who follow the scent and only pounce when your back is turned or your foot slips. Confidence in our own ability is not lacking, but what we desire above all else is the complete trust of our readers; the certain knowledge on their part that we trail no halter and that we are for the man who is in the right, whether he owns the mine or works in it.

Treading on what is supposed to be dangerous ground, we wish to assert *right now* that we are not opposed to Unionism when labor is organized on a sane basis and conducted for the good of the majority. It is also essential to fairness that such federations be endowed with moral and financial liabilities proportionate to the obligations assumed by the other party to such contracts. However, we abhor those leaders who are traitors to the cause of the men, and who grow fat on the sufferings of a misguided and trusting body of fellow-workmen.

As to the Bureau of Mines, we believe its work is beneficial and that the investigations being carried on are hastening the advance in the art of mining; however, we do not favor a further extension of the powers of the bureau, so far as coal mining is concerned, for when such a federal department crosses the line that divides the province of suggestion from that of dictation, trouble will ensue through interference in the management of private enterprise.

Furthermore, the idea somewhat prevalent outside the industry that the creation of the Bureau of Mines saved coal mining from utter destruction is erroneous. We would have continued to advance without government aid, although we welcome the valuable help they have rendered, and believe the industry is entitled to a continued careful expenditure of public money in the interest of increased safety and efficiency.

In conclusion, we will say that our chief aim is to voice the sober judgment and final opinion of the majority in our industry, to live according to new standards and not be bound by obsolete traditions. We earnestly solicit your suggestions in the interest of our common welfare. Help us make Coal Age a human document from cover to cover. It must not voice the opinion of any man or clique of men. Above all, encourage us in our ambition to be right rather than popular.

Mine Rescue Work in Illinois

By H. H. Stoek*

The State of Illinois has established three mine-rescue stations and equipped three rescue cars. Men from these cars attend all mine disasters and train mine-rescue men at the surrounding mines.

*Professor Mining Engineering, University of Illinois, Secretary Illinois Rescue Station Commission, Urbana, Ill.

Two years ago, in November, 1909, the people of this country were startled and stunned by a disaster at Cherry, Ill., which will always stand out prominently among mine casualties, not only on account of the large number of lives lost, but also because it showed that a serious calamity could be started by so simple a cause as the burning of a bale of hay. This disaster was the inciting cause for legislation, which could possibly never have been enacted but for the condition of public opinion, brought about by the disaster.

The special session of the Illinois legislature, which convened in January, 1910, passed among other laws, intended to increase safety in mining, one providing for the establishment of a mine-rescue service throughout the state. The governor was empowered to appoint a commission consisting of two coal-mine operators, two coal miners, one state mine inspector, one representative of the department of mining at the University of Illinois, and one representative of the Federal Bureau of Mines. This commission was authorized to purchase, or accept as a gift, suitably located sites for the establishment of three rescue stations, and to establish, equip and operate the same, and for these purposes the sum of $75,000 was appropriated.

After visiting a number of suggested locations, the mine rescue commission selected Lasalle, Springfield and Benton for the northern, central and southern stations, respectively. Plans for the buildings were drawn by the state architect from sketches furnished by the commission. Fig. 4 shows the Springfield station. As all three buildings were erected from the same plans and are practically identical, a description of one will suffice for all.

Buildings Provided

The foundations are of solid concrete, finished smooth on the inside wherever the surfaces are exposed. The walls of the buildings are of timber covered on the outside with metal lath, which is coated with two coats of plaster throughout. The extreme dimensions are 61 ft. 6 in. in width and 87 ft. in depth. The height to the peak of the roof is 29 ft. 6 in.

The front part of the building contains two floors, and is divided into the living apartments, office and workshop. The rear portion is one story in height, and contains the rescue chamber.

The basement contains a store, coal and furnace rooms, and has concrete floors and finished concrete walls throughout.

On the first floor, Fig. 6, at the left of the entrance, is the office of the superintendent, in which is a large closet for the storage of maps. Back of the office is a hallway leading to the dining room, which also serves as a general living room. Adjacent to this hall is a closet and toilet. In the rear of the dining room is the kitchen, off which is a commodious pantry and a rear entrance. Behind the front-entrance porch, a hallway leads to the rescue chamber, and on the right is an entrance to an equipment room, which is divided into two parts, one for the storing of appliances and the other for use as a workshop.

The rescue-training chamber and lecture hall occupy the rear of the first floor. The lecture or observation hall, Figs. 1 and 6, is a room 30 ft. by 57 ft., lighted from above by skylights, but it can be darkened when desired by curtains. The sides of the lecture hall are of glass, thus giving a full view of the training gallery, which surrounds the lecture hall on three sides. This auditorium will seat comfortably about 100 persons, is well lighted and is provided with a special lighting switch, so that a stereopticon can be used for lecture purposes. Stereopticon slides, together with notes for the same, are used by the superintendent or other lecturer at the station, and these lectures are furnished by the department of mining engineering of the University of Illinois.

Fig. 1. Lecture Room in Rescue Station

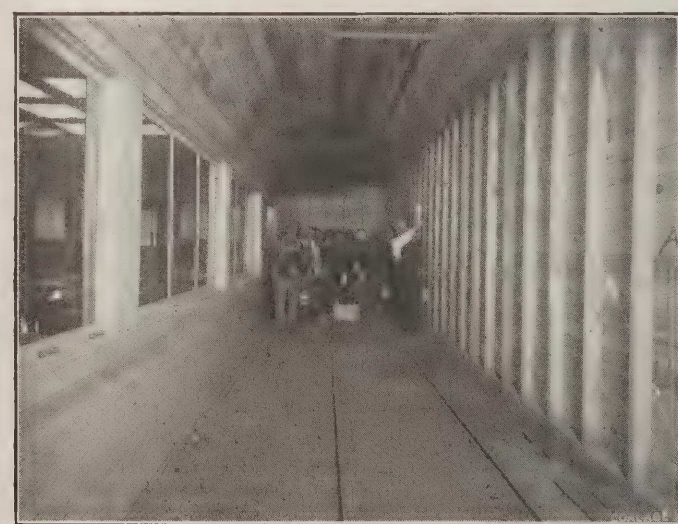

Fig. 2. Right Side of Training Gallery

The training gallery is an air-tight gas chamber, in which sulphur can be burned to produce sulphur dioxide. Other irrespirable gases may be used instead of sulphurous oxide. In this chamber training with oxygen helmets and other rescue apparatus is carried on. The right side of the gallery, Fig. 2, is 8 ft. wide and 10 ft. 4 in. high, and in this part are placed a mine track and a mine car. The left side of the gallery is only 6 ft. wide and is divided into two parts, one of which is 5 ft. 2 in. and the other 4 ft. 7 in. in height. This division allows work to be carried on in restricted quarters and the upper part also serves as an overcast. There is a toilet at one end of the left side of the rescue chamber. The

end of the gallery, Fig. 6, contains a track for a mine car and a tunnel, shown at the right, through which men crawl when equipped with rescue apparatus, in order to accustom themselves to work in restricted quarters.

The second floor, Fig. 6, contains a dormitory, in which there are twelve white-enameled iron beds. A commodious toilet room, adjoining, is fitted with lockers, shower baths, wash bowls and other toilet facilities. There is also a bathroom on the opposite side of the hall. There are three rooms which can be used by the family of the superintendent for private sleeping apartments.

The building is well lighted with electricity and thoroughly ventilated by means of numerous well placed windows. It is finished throughout in natural wood, stained a dark burnished-gray color, presenting an excellent appearance.

Rescue Cars

At each station there is a car for use in transporting the rescue appliances and the party manning the station to all disasters to the scene of an accident. The exteriors of these cars are shown in Fig. 3. Fig. 5 shows the plan of one of them and this will illustrate them all, although there are slight differences in interior arrangement. One of these cars, completely equipped, was donated by the Chicago, Milwaukee & St. Paul Ry., and another, fully outfitted, was presented by the Chicago & Northwestern Ry. The third was purchased from the Pullman Co., and refitted by the commission.

Fig. 3. Party of Rescuers Equipped with Oxygen Helmets

As shown by Fig. 5, one end of the car is occupied by the heater, coal box and the locker for linen, and on the opposite side of the aisle is the toilet room. Next come three double-compartment berths on each side of the car. There are accommodations in this section for 12 persons, sleeping singly. Next is a kitchen, fitted with stove, sink and a suitable pantry. An ice box is located beneath the car. The state room, intended as an office for the manager, or whoever is in charge of the rescue work at the mine, contains a double berth, a desk and a small toilet room. One end of the car is used for storing the rescue apparatus, and it also affords space for demonstration purposes. In one corner are three oxygen tanks connected to a pump, as shown. On the opposite side is a storage rack for seven other oxygen tanks. In one corner is a coal box and in the other a locker for pulmotor, first-aid supplies and other small articles, and for the storing of potash cartridges. The helmets are hung by hooks from the ceiling of the car or on the side, and, if necessary to prevent them from swinging, a strap is provided, which can be run to the floor and there fastened to a ring by a snap hook. The helmets are covered when not in use by a canvas bag to protect them from dirt. A work bench can be placed at one side of the car, and equipped with suitable tools needed for repair work in connection with the rescue apparatus.

Rescue Equipment

Each station is provided with an equipment of five Fleuss, five two-hour Draeger, three one-half hour Draeger and three Westphalian oxygen rescue apparatus, with two oxygen pumps and a complete outfit of electric and ordinary safety lamps, together with appliances for charging the electric lamps. There are also two complete sets of first-aid appliances, charts, etc. Some of this apparatus is kept stored in each car so that in case of an accident at a mine in the district tributary to the station, the car can be moved as soon as a locomotive can be procured.

Each station is in charge of a superintendent and an assistant. There is a manager who has charge of all the stations and cars and acts in conjunction with the commission.

The course of training consists in acquiring a knowledge of the several types of apparatus noted above and the acquirement of facility in the use of the same. Before a certificate is granted, a man must undergo the following test, completing the work within a period of two hours:

1. Make eight complete trips around gallery on ground floor.
2. Climb ten times over an overcast.
3. Carry 25 bricks over same.
4. Crawl through tunnel three times.
5. Carry four props over overcast.
6. Saw two props completely across.
7. Set five props and knock them out.
8. Hang canvas, take it down and fold it up.
9. Pull weight 60 times.
10. Carry dummy, with the assistance of another man, once around gallery, lifting it over a car.
11. Push car once around gallery with help of an assistant.
12. Make eight complete trips around gallery on ground floor.

When a man can do this a certificate is given him and also a button, showing him to be a member of the Illinois Mine Rescue Corps.

The time of training varies from one to two weeks, depending upon whether the men devote all their time to the training and live in the station during that period, or come to the station from adjacent mines and devote only such time as they can spare from their regular duties. No charge is made for instructing the men and if they desire, 12 men at a time can be lodged in the dormitory free of charge. The superintendent has the privilege of running a boarding table for which those in training pay. They can board outside the station if they prefer to do so.

The mining law passed by the legislature recently adjourned provides that a map of each mine in the state shall be filed with the manager of the rescue stations. The maps of the mines situated nearby any station will be kept in that station so that in case of an accident the rescue party can study the map while *en route*.

The same law provides that candidates for the positions of mine inspector and mine manager must pass an examination in rescue and first-aid methods.

Certification

The stations and cars were not completed and fully equipped until about June 1, 1911. The summer of last year was so intensely warm as to render it inadvisable to attempt to train men at that period of the year. The helmets on a sultry day cause considerable oppression, and the heat would be still further increased by the combustion of the sulphur. With the return of cool weather, however, a vigorous campaign has been inaugurated and the three rescue cars are now in the field, going to the various mining centers for purposes of demonstrating the use of apparatus and for giving systematic instructions in the same. A record is kept of those who take such instructions and they are given credit for having attended these demonstrations and lectures when they go to any one of the stations for final training and for the test required before a certificate and button are

granted. Up to Dec. 1, somewhat over 100 certificates had been issued to men scattered all over the state, but this number will be materially increased as the result of the active campaign now being conducted.

In each of the stations there is kept a file of the leading mining technical journals of the United States and Great Britain and there is also a mining library.

It is a source of pride to the citizens of Illinois that the state has been the first to provide a rescue service for its mines under state jurisdiction and it is believed that this is to be only part of a general educational movement that will greatly benefit the mining industry of the state.

Anthracite Coal Strike Situation

By E. L. Cole

The miners in the Union constitute a minority of the anthracite coal workers, but they will control the actions of both unionists and non-unionists. Violence will probably not effect anything in the coming strike. The washeries and stock piles are mostly away from the villages of the coal workers and the operators will be able to supply all normal demands.

Much has been said and written about the all absorbing topic for discussion which is now agitating all parties in the anthracite coal fields. The oft repeated question is, will the miners strike on April 1? The thoughtful reader is at a loss to sum up the situation for he has reluctantly formed the opinion that the average writer is biased in his views, be he a labor leader or a spokesman for one of the coal-producing companies.

The time is near at hand when an answer must be given to this momentous question which is of vital importance to the large coal-producing corporations and to the 160,000 men and boys employed by them in the production of anthracite coal for the market. It is a question of deep concern to over 1,000,000 people populating the anthracite coal fields and directly or indirectly dependent upon the unceasing production of coal for their means of livelihood and prosperity.

I shall state what I have seen and heard, so that all who have the well being of their fellow creatures at heart, will be able to draw their own conclusions with the assurance that the verdict is based on the actual conditions that confront the miner and his employer today.

The Leaders and the Led

In conversation with the more intelligent mine workers, whom it is my good fortune to know well, I have heard slip quite often from their lips the expression: *"Well! if they strike."* When I have asked them: Why do you say *"they,"* I have invariably received the reply that, "I don't belong to the miners organization, but if the United Mine Workers of America decide to strike I will strike with them."

Here it may be well to point out that while public opinion is overwhelmingly against a strike, that same public opinion will not decide the question, neither will the majority of the miners decide it, for the issue will be wholly in the hands of a small but powerful minority of coal miners, not powerful in money and numbers, but powerful in influence. What they decide to do, the vast army of mine employees will choose to do also. The miners are permitting themselves to be governed by a minority of their fellows in the economic field, while they strenuously object to any such measures being applied to them in their political activities. Surely they are not to be congratulated on the consistency of their actions.

The truth of the matter is that the majority of the mine workers have long ago severed their relations with their economic organization; they have little or no confidence in the mine leaders, and they have good reasons for that lack of confidence. They have seen their officers spending valuable time and money, jockeying for positions of influence and ease in the labor world. They have seen them conducting elections in an unscrupulous manner. They have seen their lesser officers spending their time and the money filched from the pockets of the mine workers, in the saloons of the coal fields in much the same manner as a ward politician whose whole purpose in life is to perpetuate himself in power so that he may continue to live on the sweat of his dupes.

One-half Million Men Are Required to Mine the Coal Demanded for Consumption in This Country Alone

Union Stronger in Influence than Funds

The position of the miners is rendered difficult by the fact that less than 30 per cent. are in good standing in the labor unions, so that the treasury is far from overflowing. Thus the miners' ranks do not present an unbroken front to their employers. And this is due in no small measure to the fact that race prejudice is an active factor separating the mine

workers. It is well known that nearly all the organizers receive comfortable salaries, far more than they would receive in their usual vocations at the mines. They are nearly all of the English-speaking races, although the financial support of the Union is drawn in the anthracite field from the foreign miner. It is the foreign workmen who are now the aggressors. They are believers in *direct action,* and they point with pride to their remarkable achievements in 1902 when they marched in bands 10,000 strong having base-ball bats as weapons. By threats of physical violence they succeeded in closing one colliery after another, regardless of the fact that some of the mines were manned entirely by Americans who preferred not to belong to the union and whose wish it was to continue at their work of producing coal.

The tactics which are known in the labor world as *direct action* were in no small measure responsible for the mines being tied up for nearly six months in 1902, and some of the miners have expressed the hope that they will be able to repeat their tactics and again tie up the mines until their demands are granted.

A National Coal Strike

Some profess to see a gleam of hope in the plan of ex-president Lewis who is advocating a united stand of both the bituminous and anthracite miners. He would cause the entire organized army of soft-coal workers to stand idle until the demands of the hard-coal workers were granted, regardless of the fact that the bituminous miner may have previously succeeded in reaching an amicable agreement with his employer. The futility of such a plan is evident to the student of the labor movement for there are in this country in round numbers 800,000 mine workers, less than half of them are organized and in the event of a strike, the unorganized soft-coal miners would undoubtedly continue at work, thus enabling the operators who employ them, to capture markets permanently that are now held by the employers of unorganized labor. For it is no secret that we are able today to supply coal far in excess of the actual market demand. Thus the union miner, in the soft-coal region, if he stood idle for the sake of his anthracite brother would be placed in the position of robbing himself for the sake of affording the anthracite leaders an opportunity to experiment with the system euphemistically termed *direct action* but better termed *unrestricted violence.* The fact that a large body of miners would still continue at work would be a most formidable obstacle in the path of organized labor. Its leaders see the danger that lies ahead in case of a general strike, and they are adverse to it, although they are being daily urged to promote it by those who favor the plan and who point out the gains made by the English labor men in their recent general suspension from work.

Lack of Cohesion

The miners seem to lose sight of the fact that the English labor movement is conducted by people who speak a common tongue, while here we have the most cosmopolitan body of men ever gathered together, men who differ in race, and who hold political opinions which are at variance one with another. As proof, witness the acrimonious debate which lasted more than one day at the recent convention of the U. M. W. of A. The wrangle was precipitated by the introduction of a resolution to indorse a political party, the tenets of which most of the miners do not in any way understand.

In Case of a Prolonged Strike, the West Virginia Mines Would Greatly Benefit. Above View Shows Sun Colliery No. 1, in the New River Field of Southern West Virginia

Furthermore, a general strike to be successful would necessitate the aid of the railroad men engaged in transporting coal to market. These men would be unable to aid the miners unless they first would repudiate the contracts they have entered into with their employers, and it is worthy of note that no body of railroad men in this country has yet dishonored itself and the calling by repudiating its contracts. These have been secured only after years of earnest effort. By them railroad employees have practically eliminated the use of that crude weapon—the strike—in their efforts to improve the condition under which they labor.

It would undoubtedly prove a most arduous task for the miners to convince their fellows who are engaged in the transportation world to desist from hauling coal from either storage yards or washeries for the purpose of enabling the miner to defeat his employer.

The hope of the miners that they can inaugurate a general strike and carry it to a successful conclusion is but an iridescent dream into which they have been hypnotized by a western labor leader. He is now in charge of the general strike of the New England mill workers; but recently he toured the coal fields rousing his audiences to a high pitch of enthusiasm by his glowing word-pictures of the possible fruits of a general strike. I have been advised that it is his intention to return to the coal fields if the strike ensues, for the purpose of promoting that general strike, of which he is such a strenuous advocate.

Temporary Vocations

Some of the miners profess to believe that they can repeat their migrations of 1902 when thousands of them entered the industrial centers and readily secured employment at wages that enabled them to support themselves and assisted them in supporting their families at home. Those who hold such an opinion should be disillusioned, for the student of industrial conditions is aware of the fact that large employers of labor are not in need of additional hands today. Few, if any, of our large industries are being operated to their full capacity, and in no quarter is the demand for material greater than the supply.

The strike of a decade ago was but six weeks old when the public was asked for financial assistance and most liberally did it respond, but today an appeal for a sustenance fund would fall unheard, not because of the unwillingness of the toilers in other fields, but because the head of the average family has little or no money to bestow upon others, due to the world wide increase in the cost of living. Moreover the large body of men who are unsteadily employed will be unable to assist their fellows should they so desire.

Public Not Anxious to Pay More for Coal

The aid received from the public was in no small measure responsible for the fact that the miners were able to win their strike of 1902. The coal-producing companies were not engaged in producing coal for pleasure, so they added the increased cost of labor to the selling price of coal, which action the public immediately resented. The consumer was placed in the position of the innocent bystander who attempts to interfere in a family disagreement. The reconciliation was indeed effected but at the public cost. The coal buyer will be loath to aid the miner again for he will be aware that the inevitable result will be to increase the cost of an article which forms one of his daily needs. The managers of the vast anthracite coal operations must decide to raise the price of coal if they would hope to continue to realize an equitable return on the extra hazardous investment that they have made.

There is another factor that will militate against the miners, and that is the great increase in the machinery used in the washeries. This replaces unskilled men by mechanics, who being fewer in number and less sympathetic with the miners, are more likely to continue at work. In fact, a few years ago when the U. M. W. of A. ordered a stoppage of work pending negotiations, General Manager Richards of the Philadelphia & Reading Coal & Iron Co. was able to ship 40 cars of coal per day from Rausch Creek washery, without the use of any regular employees with the exception of the foremen, due to the fact that the work is almost entirely done by automatic machinery. The total tonnage of all the washeries, together with the coal in the storage yards, would enable the operators to prevent the repetition of the famine of 1902.

Direct Action Fore-Warded

Should the miners in the event of a strike attempt to repeat their tactics of ten years ago and march to the washeries in an effort to stop their operation, they would undoubtedly be met by the highly efficient Pennsylvania State Constabulary. The force has been in existence long enough to demonstrate that it is equal to any emergency which may arise. It may be added that the present force of state police may be insufficient to cover the entire zone of labor troubles, but it is well to remember that as there is a community of interest between the coal, railroad, manufacturing and commercial men, it would not be an insurmountable task for them to unitedly invoke the aid of the state legislature of Pennsylvania to increase the numbers of the state police, provided that they produce data to substantiate their claims for additional protection. To those of my readers who may doubt the foregoing, I need but point out that only the united action of the Pennsylvania business men prevented the disintegration of the state police. In the last session of the legislature, efforts were made to prevent an increase in the salaries of the members of the force, which was only an indirect attempt to cause a depletion in the ranks of the state police. It may be well to further note that the fight against them was led by one of the state leaders of the American Federation of Labor, who recently toured the coal fields at a salary almost double that which he receives as a pipe cutter. The burden of his lecture was a recital of his efforts to legislate the state police out of existence, and he proudly acclaimed that he would abolish the most expensive but effective preventative of mob rule that the State of Pennsylvania ever possessed.

Typical Mining Town in an Unorganized West Virginia Field

Storage Yards Largely Away from Coal Field

Turning to the operators, we find that the struggle of 1902 taught them the necessity of building storage yards so that they would not be entirely unprepared to meet their employees in future struggles in the economic field, and wisely they have chosen the locations of most of the yards within the reach of the consumer, out of the zone of possible labor troubles. It has been estimated that the operators will have sufficient coal on hand, together with the possible ouptut of their washeries, to supply the normal demand for coal.

It is this strategic position of the operators that has given rise to a fear of a lock-out of the miners on Apr. 1, but the student of economic conditions quickly sees that a lock-out is not without its perils to the mine owners. For instance, every summer all the progressive gas companies inaugurate strenuous campaigns for the substitution of gas ranges for anthracite-coal consuming stoves. In the fall of the year the central stations, who quite frequently are large users of bituminous coal, endeavor to supply customers for their winter heating from their central stations, and this phase of the problem is one fraught with the danger of no slight economic loss to the coal-producing companies, and one that could hardly be avoided if a protracted struggle should ensue.

Higher Costs for Miner and Operator

Though the operator occupies an excellent strategic position, his path is not an easy one, and the question for him to decide is what course shall he pursue so that he may continue to keep his property on its present dividend-paying basis. While it is true that the miner has suffered an increased cost of living, the operator has also suffered from progressive increase in the cost of mine supplies during the past nine years, in addition to which he has been compelled to make heavy expenditures for the purpose of mining seams of coal which lie deeper than he has formerly worked, and that hitherto have remained untouched, due to the enormous cost of reaching them.

It has been said that the miners and mine owners might agree to a slight increase in the compensation of labor, the operators to add to that increase a sum of money to compensate them for the higher wages and heavy expenditures heretofore mentioned, but a student of the situation realizes that competition is liable to make the problem more difficult, for, though the increase be only 10 per cent., the additional cost would be sufficient to cause many large consumers of anthracite to substitute bituminous coal, so that both miner and owner would, by such measures, receive no permanent gain. There is the further danger that harassing legislation may be invoked by the politicians who wish to make a play to the gallery, hoping thereby to further their personal political ambitions. Undoubtedly an increase in the cost of coal will bode ill for the operators if the political agitator should seize the opportunity and succeed in further inflaming the public mind against industrial corporations.

British Coal Trade Crisis

Special Correspondence

Having regard to the world-wide interest in the negotiations between the coal owners and the representatives of the workers to establish the principle of the minimum wage in British coal mines, it may be opportune to append a diary of the crisis as follows:

Oct. 7, 1911—Annual conference of Miners' Federation. Conference met at Southport and resolved to "take immediate steps to secure the individual district minimum wage." In the event of the employers refusing, Rule 21 to be put in operation.

Oct. 14-30—Minimum-wage demands were refused by the employers in all districts except Warwickshire.

Nov. 10—The minimum-wage demand was considered by the Conciliation Board for the federated districts of England and North Wales (Lancashire, Cheshire, Yorkshire, Midlands, Somerset and North Wales). The coal owners' representatives stated they *could* recommend the adoption of the principle of the minimum wage; but as the matter was beyond their power to decide, they proposed to take it to their districts. The meeting was, therefore, adjourned.

Nov. 14 and 15—As arranged, on Oct. 7, a special conference of the Miners' Federation was held in London. In view of the acceptance of the principle of the minimum wage by the coal owners' representatives in the English area, it was decided to adjourn the conference, pending further efforts to promote a settlement. The executive was instructed to invite the coal owners generally to a national conference.

Dec. 18—On this date the English Conciliation Board again postponed decision on the question at issue.

Dec. 21—The adjourned conference of the Miners' Federation decided to take a ballot of the men as per Rule 21. Each county or district was instructed to prepare a schedule of demands. Decision made to continue negotiations.

Jan. 10-12, 1912—Ballot of workmen taken.

Jan. 13—The country realized that the strike majority would be more than the two-thirds required by the Federation rules, and there was a sharp rise in coal prices.

Jan. 16—A meeting was held of the miners' representatives on the English Conciliation Board to frame proposals for the practical application of the minimum wage to coal mining.

Jan. 17-19—The Miners' Federation held a conference at Birmingham. The ballot result was announced, showing 445,801 in favor and 115,919 against a strike—majority, 329,882. In view of these figures it was decided to issue strike notices. At the same time the employers were invited to continue negotiations.

Jan. 23-27—The negotiations were continued by the English Conciliation Board conference. The task of finding a basis of settlement was delegated to a joint subcommittee. This joint committee exchanged views upon the demands of the miners, with reference to abnormal places and the minimum wage. It was decided to submit a report to the owners and miners in the different districts within the federated area.

Feb. 1—Notices handed in at collieries in South Wales coal field to stop work at the end of February, a month's notice being necessary under the South Wales wage agreement. On behalf of the members of the Enginemen, Stokers and Surface Craftsmen's Society, who demand an eight-hour day and better wages, notices were tendered. The number of workers affected by the notices is about 200,000.

Feb. 1-2—Delegates of Miners' Federation, representing over 650,000 men, passed resolutions upon the minimum wage to furnish basis upon which negotiations may be conducted in the national conference of coal owners and workmen, on Feb. 7. Agreed that the following claims be formulated for an individual minimum wage in each district for piece-workers at the face of coal:

Yorkshire	7s. 6d.[1]
Lancashire	7s.
Midland Federation	6s.@7s.
Derby	7s. 1d.@7s. 6d.
Nottinghamshire	7s. 6d.
North Wales	6s.
Leicestershire	7s. 2d.
South Derby	6s. 6d.
Somerset	4s. 11d.
Bristol	4s. 11d.
(While this is fixed as a minimum, it is understood that it will not effect in any way a higher rate than 5s. and 5s. 3d. already prevailing in the coal field).	
Cumberland	6s. 6d.
Scotland	6s.
South Wales	7s. 3d.@7s. 6d.
Northumberland	6s.@7s. 2d.
Durham	6s. 1¼d.
Forest of Dean	5s. 10d.
Cleveland	5s. 10d.

[[1]For the information of those who are not familiar with English money, we desire to say the English shilling (s.) equals 24.3c. and the pence (d) equals 2c.—Editor.]

No underground adult worker shall receive a rate of wages less than 5s. per shift (but this resolution is not to apply to Somerset, Forest of Dean, or Bristol).

Individual minimum wages for all piece-workers, other than those working at the face of coal, to be arranged by the districts themselves, and to be as near as possible to the rates paid at the present time in each district.

The rates paid to the underground workers who are paid by day wage left to the districts to arrange.

List of boys' wages also left to the various districts, but they are not to be less than present wages nor in any case less than 2s. per day for any boy.

Conference of the Federation to be called to meet in London, on Feb. 13.

New Test for Firedamp

A simple contrivance which is capable of being attached to any safety lamp has been designed by Henry Briggs, of the Heriot-Watt College, Edinburgh. By means of his device he claims that a remarkably small percentage of firedamp can be detected in mine air, that indeed, it is one of the most accurate and delicate ways of detecting gas.

The attachment, he explains, consists merely of a loop of copper wire supported on a vertical brass stalk, which extends through the oil vessel of the lamp. When it is required to make a test for gas, the loop is moved into the flame, which then becomes nonluminous, allowing the gas cap to be clearly seen if firedamp be present. The loop obviates the necessity of drawing the flame down when looking for gas; hence there is no risk of losing the light.

Changing from a working to a testing flame, or *vice versa,* is practically an instantaneous operation. Any kind of oil or spirit and any shape of wick may be used. The loop does not interfere with the lighting power of the lamp, nor does it curtail the height of the flame when testing.

On John Bull's Toes?

The following editorial excerpt from the *Iron and Coal Trades Review* (London, England) is a graceful—though apparently unwilling—acknowledgment of our growing importance in the export trade:

A generation ago, British coals were thought to be practically beyond the reach of competition, and the only preoccupation of collieries and shippers was to anticipate the requirements of a trade which seemed capable of indefinite expansion, and which, indeed, is still expanding. It is true that exporters had been made to realize the existence of coal in America by the loss of the West Indian trade, but this was soon all but forgotten in view of the rapid increase in the quantities taken in other directions. The knowledge of the existence of coal deposits in other countries was of the vaguest character, and the subject was casually dismissed by an emphatic declaration that they were of no account in a competitive sense, and developments on the Continent, as in the United States, were treated with indifference until British shippers were startled some 10 or 12 years ago by the invasion of European markets by American coal in small quantities.

Coal Production of Austria

The total production of both coal and lignite in Austria for the year 1911 was 40,116,743 metric tons, as compared with 38,006,840 tons for the year of 1910. The coke production for 1911 was 2,076,978 metric tons, as compared with 1,999,106 tons for the year of 1910, the production of briquettes in 1911 was 347,597 metric tons, an increase of 13,379 tons for the year. Two-thirds of the briquettes were made from lignite.

A Self Dumping Car Haul System

Special Correspondence

A description of the Greene car-haul and automatic-dumping system as installed at the Burnside colliery in Pennsylvania. The apparatus includes a novel arrangement for recording the work of the tipple and is an important labor-saver.

The Philadelphia & Reading is the first company to install the Greene self-dumping car haul in the anthracite regions and C. O. Bartlett & Snow Co. have but recently finished one of the finest jobs of engineering in Pennsylvania, in adapting the patented idea to local conditions found at the Burnside colliery. The accompanying illustration conveys an idea of the old plant, which was displaced, and shows two loaded cars being elevated while two empties are being lowered on the parallel track.

This is the simple plan of cable haulage found in so many mines everywhere. It will take up enough cars and does a service quite adequate in most instances, but a much greater economy can be effected by the use of the installation to be described.

INSTALLATION AT THE PHILADELPHIA & READING COAL & IRON CO.'S BURNSIDE COLLIERY

Method of Operating

The Burnside breaker receivers coal from three openings namely Burnside shaft, Burnside drift and Stirling slope. Tracks approach the breaker from three directions around curves and limited space for track storage of waiting cars demands speedy handling of the loads and empties to keep the several workings clear at all times. The new self-dumping car haul will do this and more. Variable speed motors furnish the power to run the haul from 44 to 88 ft. per minute, hence a shut-down in the breaker can be compensated quickly by speeding up the haul and quickly reducing the accumulation of loaded cars.

To describe the principle of the Greene self-dumping car haul in the simplest manner, it might be likened to a common type of bucket conveyor, as it has the same endless chain, though lacking buckets of the stationary character, which are supplied by cars as they are taken up at the bottom on the lower track and released at the base of the upper track. Illustrations are given herewith to help understand the general makeup of the machine, which is simple enough despite the wonderful results that it will accomplish.

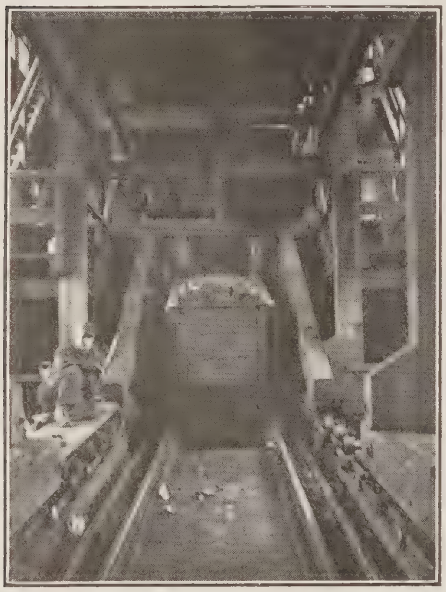
It is simply an endless chain revolving about a sprocketed wheel at either end of two tracks placed one above another, the chain having protruding cross bars that engage a loaded car behind its rear wheels and after having slightly elevated it to accommodate the 30° grade and avoid spilling coal in the ascent, it goes to the breaker. Then a swinging lift, which is not such a simple matter and requiring description later, elevates the car, as it is discharging its load of about four tons of coal, and placing it on the upper track leaves it to the cross bar to return again to the tracks leading back to the mines. Beside the swinging lift there is another auxiliary device at the base that prevents choking, called the feeder haul, and one other mechanism just above it, known as the cross bar and empty car release that operate automatically also and are worthy of description.

Feeder Haul

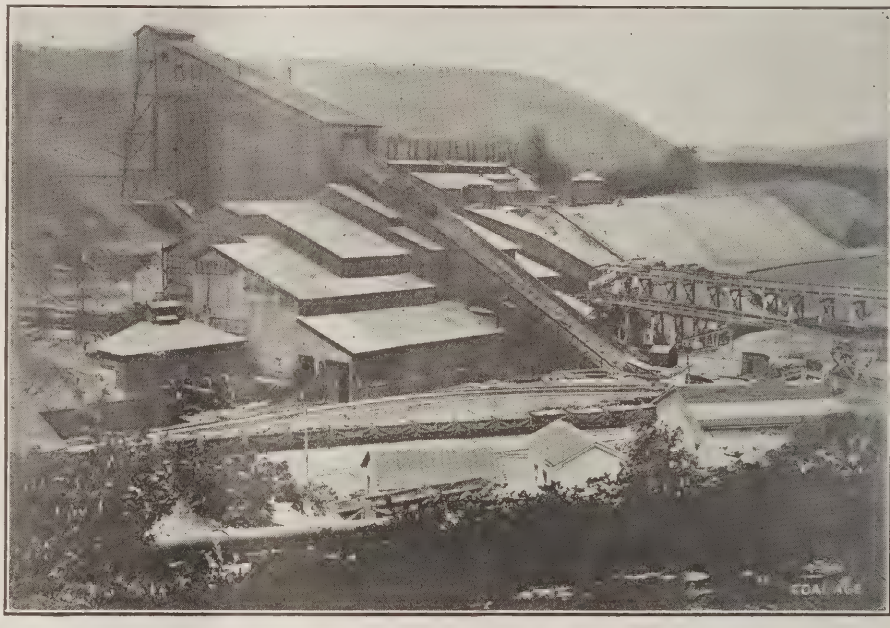
The feeder haul is a machine in itself consisting of an endless chain on two sprocketed wheels geared to the larger

sprockets that operate the main haul. The chain has two swinging catches or dogs that perform the functions of feeding cars into the main haul when coming in contact with three pieces of cam track that raises behind the car axle and pushes it forward at the proper interval and releases it again to wait for the next cross bar.

To be exact, we will follow the process of cars going over the feeder haul. As the train approaches, the head car is caught by a dog standing erect and passed forward to where a man pulls the coupling pin. At this point, let us note that this is the first man to have anything to do with the machine and remember that there is just one other man about the entire haul. This latter man has little to do but stand guard at the top, but that is necessary and when compared with the number of men used on the former car haul, a great saving is represented in wages alone.



Automatic Tipple



The Old Installation with Parallel Tracks

After advancing the car to about the center of the feeder the dog is dropped to be raised again a few feet ahead to advance the car left in mid track last trip, till it is taken up by the cross bar and sent up the incline. This cross bar is a tubular axle extending beyond the car wheels, and having wheels which run on a track of their own. It is impossible for the cross bar to miss its hold or for cars on the feeder track to interfere with its functions because of the simplicity of the accessory parts and by reason of a bumper that automatically checks waiting cars. Nor is the feeder haul a necessity as the cars can be fed by hand.

Dumping Arrangement

At the head of the haul the swinging arm lift comes into play by throwing the catch on the car door so that discharging begins with the door partly opened and continues as the car moves up the curved elevation until empty. The several types of cars have been taken into consideration, a cam track being furnished for lift end cars (though this is not the type at Burnside) so a projection on either side of the car trips the catches and the door swings open. At the same time the car notifies the swinging arm lift that it is coming and by the same automatic devices the lift, which really consists of two parallel arms is thrown in gear and receiving the emptied car, raises and places it on the upper track and the cross arm, now in front, checks its descent by gravity down the incline to the mine tracks.

Here again the entire process is automatic and the man shown in the illustration is doing what he does most of his time except in case of emergency resulting from interference in some part of the breaker or about the mines. An intelligent boy may do as well, as all that is required of him is to throw the switch that starts the electric motors when they may have been cut off by safety switches at the bottom or other places in the system since this provision has been made for fool protection and in case of unforeseen emergencies. The power can be thrown off anywhere but can only be turned on at the head and only there when all other switches are closed indicating that everything is allright along the entire line. The man at the head therefore is merely the watchman and acts cautiously and only on authoratative instructions.

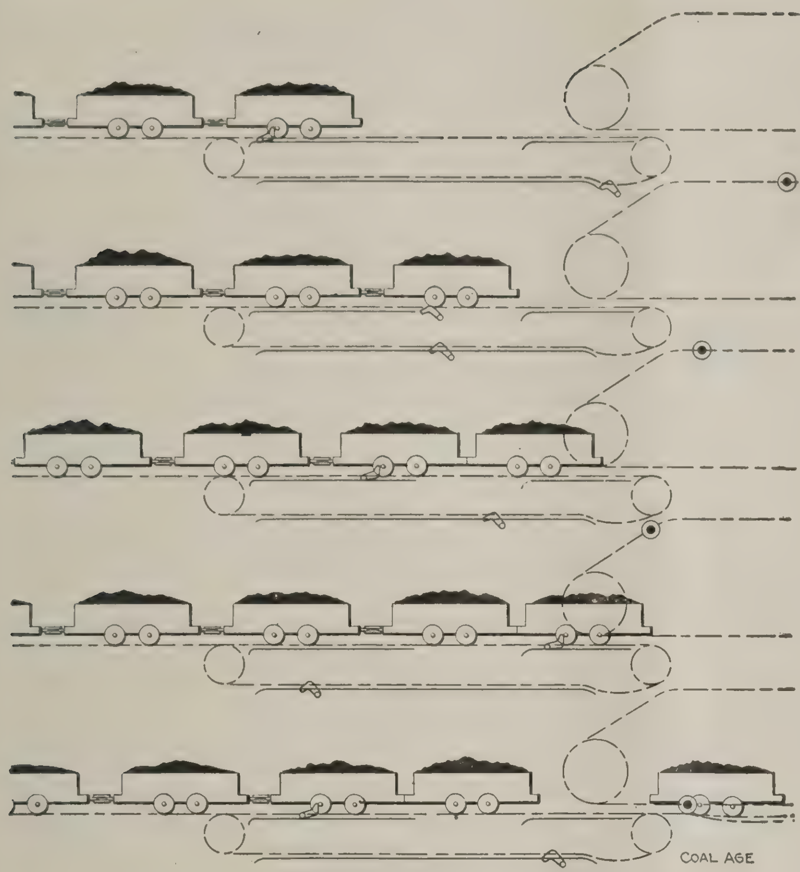
In the Greene method the car must pass through one more important process before getting out of the system at the base of the incline, where the cross bar must be removed from under the wheels and the break in the track closed for the car's passage.

The important principle in this operation is that of a balanced track and a corresponding cam release device. Remembering that the car track is within the track traversed by the cross arm wheels, we have the upper end of the balanced track elevated as the car descends hence it stops the car and the cross arm being free, slips beneath the balanced track to catch the release that trips the balance downward and cars pass on to tracks as desired. The cross arm has now made its trip and proceeds to repeat the process, while the balanced track is thrown back into position by the weight of the car passsing over it.

The Automatic Recording System

These are the main features, but there is more and to the operator the remainder is of even greater importance than the rapid despatch of 120 to 130 four-ton cars per hour, employing the services of two men, with safety provided for both men and equipment, and the assurance that the machine on the job is equal to all emergencies without extraordinary exertion.

The most valuable part about this invention is its reliability in recording its own work and affording means of detecting the responsibility for its shortcomings. If the average of its performances is not lived up to there has been a way provided for telling who is to blame and somebody has to account for it. Electrically operated Bristol recording dials tell the tale. In the morning the red finger on the clock dial tells the hour and minute of first movement and the "carpet" awaits an explanation for



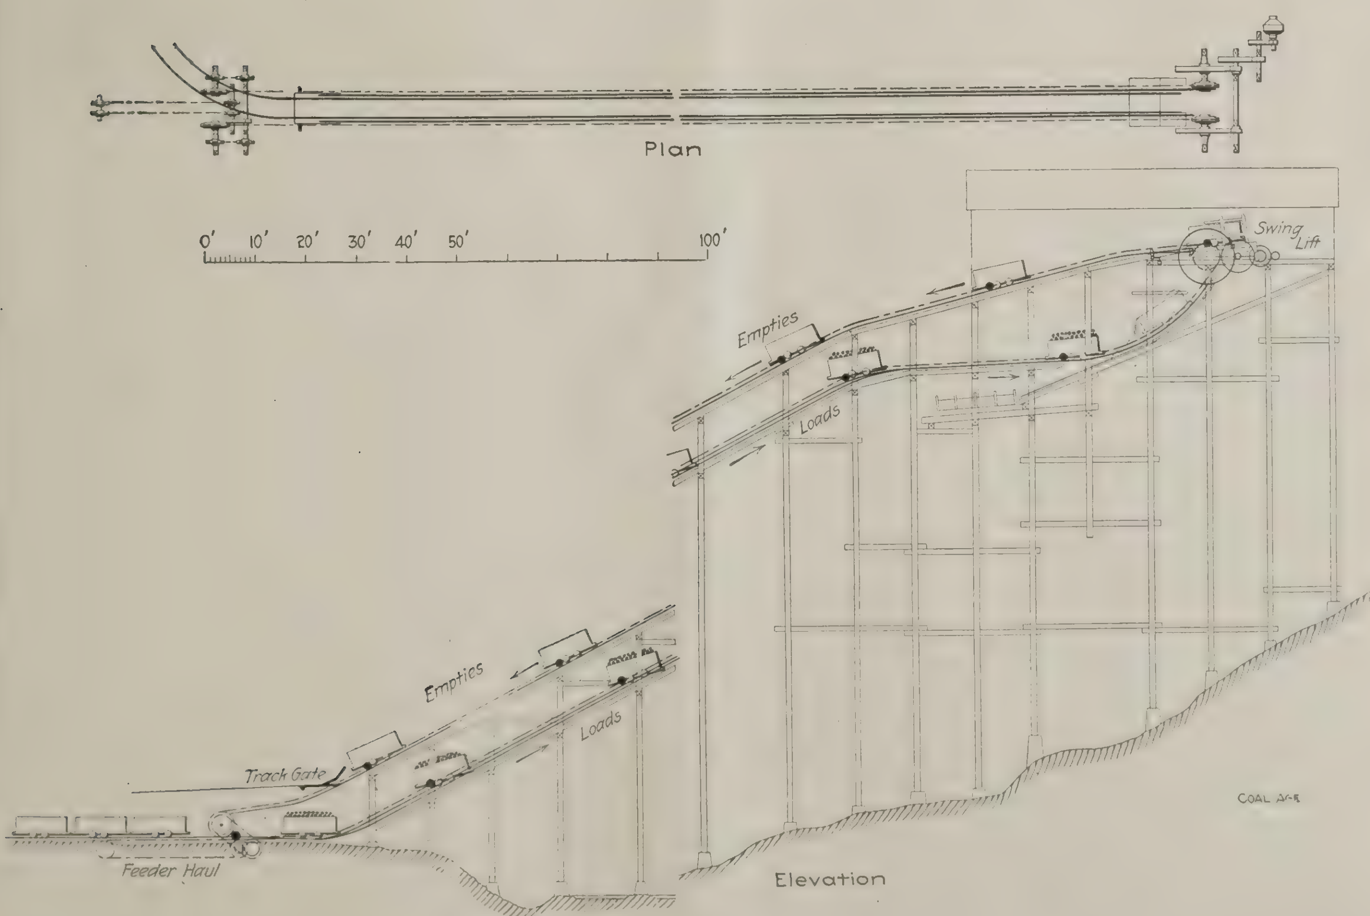
SKETCH SHOWING *Modus Operandi* OF FEEDER HAUL

tardiness if it exists. The superintendent can sit in his office, too, and look up to see that a stop has been made and if prolonged he can hurry to the scene or use his telephone to find the cause and speed its remedy.

Then at night he knows the number and length of stops that were made and the responsible party may be asked to explain these for the dial tells the tale truer than some men on the job care to disclose it. He is also furnished in the same manner the true record of all the cross bars that passed the feeder without cars, as well as the number that took cars, and that tells him more of the story of the day's work.

The Burnside colliery is fed by the openings as named above which have the following capacity per day; Burnside shaft, 400 cars; Burnside drift, 200 cars; Stirling slope, 250 cars; making the total, 850 cars each day. A day at the breaker for handling coal consists of eight and a half hours, not allowing for stops that occur at nearly every breaker each day on account of a slip somewhere or because of a breakdown due to a worn-out part.

Electricity is the motive power employed throughout which adds further efficiency by reason of the time saved in starts and stops.



PLAN AND ELEVATION OF CAR HAUL AND DUMPING ARRANGEMENT

Methane in Coal Dust Explosions

By F. I. Wilbur*

A concise restatement of ascertained facts relative to the action of methane in promoting coal dust explosions, drawn from publications on the subject, domestic and foreign. The opinion of Mr. Wilbur is that coal dust is merely a contributory factor in mine explosions, contrary to recent reliable investigation.

*1503 Rhode Island Ave., Washington, D. C.

In 1845 Faraday and Lyell in England endeavored to call the attention of the coal mining world to the action and effect of coal dust in aggravating and extending the injurious effects of fire-damp explosions. Later, in 1867, M. Verpilleux of France also announced his conclusion that coal dust was an important factor in mine explosions. Since then many workers have investigated the subject and its importance as a factor in aggravating mine explosions is generally conceded. Of late there has seemed to be a tendency among writers on mine explosions to overestimate its importance and to assign it a place as a primary cause of mine explosions instead of giving it its proper place as a secondary or contributing factor.

The British Royal Commission appointed to investigate the causes of accidents in mines reported with regard to coal dust (See II Report of the Royal Commission, 1894, p. 24) that:—

1—Coal dust from many seams is as sensitive to explosion as gunpowder itself.

2—Coal dust is sensitive to explosion in proportion to its freedom from impurities.

3—A supply of oxygen, such as is furnished by brisk ventilation makes a coal dust explosion more probable and severe.

4—A gas explosion in a fiery mine may be carried on indefinitely by coal dust raised by the explosion itself.

Factors in the Susceptibility of Coal Dust

Most investigators consider that the explosibility of coal dust depends on:—

1—Its fineness. It is the very fine particles of dust which readily ignite.

2—Its dryness. Damp or wet roads are seldom involved in an explosion, which the dust on dry roads propagates.

3—Its purity. If the coal dust be largely mixed with an incombustible material such as stone dust, it becomes so diluted and its particles become so separated one from another that they can not propagate the flame and carry on the explosion.

4—The thorough mixing with air. Coal dust explosions cannot take place unless the cloud of dust is blown up or stirred up with the air and thoroughly mixed with it. The same is true of gas explosions which are impossible unless the combustible gas be intimately and thoroughly mixed with air. It has been noted as a curious fact in many recent so-called coal dust explosions that the face of the coal has not been affected, the force of the explosions being almost entirely confined to the main intake airways. (See Engineering and Mining Journal, Vol. 89, p. 1030). A further curious fact is that an excess of dust will prevent or extinguish an explosion.

L. T. O'Shea says (See "Elementary Chemistry for Coal Mining students," 1911, p. 272) that the great difficulty in the case of colliery explosions is to prove, without any possibility of contradiction, the absence of any trace of firedamp at the moment of ignition. Nevertheless he cites several instances where coal dust seems to have been the chief factor in a mine explosion.

The Absence of Gas in Explosions

It seems, however, impossible to eliminate the possibility of the presence of more or less methane in all of the so-called dust explosions. The Report of the British Commission on Accidents in Mines, 1886, (See p. 113) after giving some interesting facts about the effects of blown-out powder shots in the presence of coal dust, state that wherever a coal is worked which contains inflammable gas, the atmosphere in the vicinity of the workings, however efficient the ventilating arrangements, will at one time or another, and it may even be said generally, contain some small proportion of fire damp. If the atmosphere contains less than from 2 to 2.5 per cent. of its volume of marsh gas it cannot be detected by the elongation of a lamp flame or the appearance of a cap upon it.

Rollin T. Chamberlin found (See "Notes on Explosive Mine Gases and Dusts" Bull. 383, U. S. Geol. Survey) that analysis of gas obtained from crushing samples of coal showed that it consisted equally of methane and nitrogen each yielding nearly 40% of the total. This fact explains why the sensitiveness of marsh gas to explosion is increased by the presence of coal dust in the atmosphere, and also why air which seems free from gas when tested by a lamp flame may become explosive when laden with fine dry coal dust.

Galloway found that the presence of coal dust made even 0.892 per cent. of gas in the air explosive. Similarly Abel found that when marsh gas to the amount of only 2 to 2.75 per cent. was present in a coal-dust laden atmosphere travelling at 600 feet per second it would readily explode, and that some dusts were so sensitive that even 1.5 per cent. of methane became explosive in currents of low velocity

The Crevice Gas in Coal Measures.

Methane variously known as carburetted hydrogen, CH_4, marsh gas, fire-damp, "fire" or "gas" exists pent up in the coal itself where it has developed from the progressive formation of the coal beds. In some shallow mines it is rarely if ever detected as it seems able to escape from such mines to the surface through the intervening permeable strata. Other seams give it off in large quantities, especially if they have been long worked and have thus afforded an outlet to drain off the gas from the other seams. It is generally most abundant in seams of much depth where it is given off from the strata and also from the face of the coal and cracks in the floor and roof. If the gas be given off in very large amounts from these cracks it may cause a heaving up of the floor or a falling of the roof.

Sometimes the pressure of the enclosed gas is as low as 30 lb. per square inch, but in many cases the measured pressure of the pent-up gas has been found to be from 460 to 900 lb. per square inch. Under such enormous pressure there is always a liability to sudden outbursts of the gas, which even in the absence of flame sufficient to cause an explosion, are very dangerous as they make the air currents foul and dislodge material. Where the pressure is great the issue of gas from the coal is accompanied with a hissing noise like escaping steam. Such outlets of the gas are called "blowers."

When a coal seam is aproached in sinking shafts sudden outbursts of fire-damp may occur, especially after a number of shots have been fired and have thus opened crevices for the escape of the gas. In all such cases the atmosphere should be tested with a safety lamp before proceeding with the work.

Explosive Mixtures of Methane

The proportions in which mixtures of marsh gas or methane without coal dust explode on ignition appear to range between 7.14% and 16.67% of methane. Beyond these limits the mixture of pure methane and air is inflammable but not explosive. Less than 5% of methane is not even inflammable though under certain conditions the Royal British Com-

mission on mine accidents found that even 4% was dangerous. With from 5% to 5.5% of methane, or one part of methane to 19.17 parts of air they found that an atmosphere became explosive. Coquillon found that in his investigations one part of methane to 16 of air or 5.9% of methane became explosive and Wullner and Lohmann in their experiments in connection with the Prussian Firedamp Commission between 1881 and 1887 reached the same conclusion.

From these proportions the violence of a methane explosion continues to increase in direct ration to its proportion of methane until it reaches 10.3% of methane or one part of methane to 8.3 parts of air. Mallard and Le Chatelier found that this proportion gave the maximum of explosive violence. From this point each increase in the amount of methane correspondingly diminished the violence of the explosion and when the methane proportion reached 16% its mixture with the air ceased to be explosive.

Red hot wires can ignite mixtures of methane and air, those having 6.6% of methane being most easily ignited, but all mixtures having 5.9% of methane can be fired. Methane itself although inflammable is a non-supporter of combustion.

Phenomena of Diffusion

Methane is only half as heavy as air and therefore has a tendency to seek the highest point and, if sufficient ventilation shafts were provided, a mine would doubtless be able to keep itself free from dangerous proportions of methane by natural ventilation. It always has a tendency to accumulate wherever there are crevices in the coal, especially in the holes and fissures in the highest point it can reach, such as the mine roof. If these crevices are suddenly opened by the miner's pick or any other cause the gas rushes out and seeks again to rise. If it cannot escape it necessarily becomes mixed with the atmospheric air, especially where there is a brisk ventilating current which increases its attenuation and intimate mixture to a dangerous degree. After being mixed with from 6 to 12 times its volume of atmospheric air it is in a highly explosible condition and if by chance it then comes in contact with a miner's naked light or anything that will ignite it, a fearful explosion almost like that of gunpowder follows.

After the explosion it is found that the methane has combined with the oxygen contained in the air of the mine in such a way as to resolve the CH_4 and air into (1) carbonic dioxide (CO_2), popularly known as blackdamp in the mines, (2) H_2O in the form of water or steam, and (3) free nitrogen. Unlike methane the CO_2 does not rise but settles in the lowest parts of the mine.

It is rare that methane is found pure in mines as it is usually mixed with other gases chiefly carbon dioxide and sulphuretted hydrogen which tend to reduce the force with which it tends to explode. It is found that when an explosive mixture of methane is diluted with one-seventh of its volume of carbon dioxide, it ceases to be explosive.

Some interesting facts with regard to methane are given by Robert Wabner, (See "Ventilation in Mines", p. 22). He says that once mixed with air, methane (CH_4) will not separate again. When an explosion of this gas occurs two shocks—the shock and counter shock are produced in quick succession. The ignition temperature of CH_4, is 650° C according to Demanet (see his "Traité d'Exploitation des Mines de Houille," 2d Ed. Vol. II, p. 61), or 780° C. according to Kohler.

Ignition of Methane

CH_4 is said to have been ignited by the friction of a drill working in hard sandstone. In a petroleum shaft of Galicia where a miner worked without light because of the shallow depth of the pit, an explosion is said to have been caused by the stroke of the pick.

According to Dr. Brookman of Bochum, the product of the imperfect combustion of methane is ethylene or olefiant gas (C_2H_4) and not carbon monoxide (CO), hence Wabner thinks, coal dust must be the sole cause of the formation of CO and of the poisonous and dangerous character of the afterdamp.

The stronger the ventilating current the greater will be the quantity of dust that it carries with it and the farther will it be transported from the center of production by the ventilating current as it traverses the mine. This fact should be considered in the adoption of any artificial ventilating systems. Strong currents also increase the dryness of the transported dust, and consequently increase the liability to explosion.

Wabner says that certain sintering (clod) coals and non-caking coals in many districts especially when present in thick seams have long been known to possess the dangerous property of occluding and condensing oxygen. This gradually enters into combination with the carbon to form carbon dioxide, the heat thus generated producing spontaneous ignition and disastrous pit fires. The dusty state of coal favors the absorption of oxygen and spontaneous heating.

Pressure of Coal Gas

Towards the interior of coal the pressure of methane materially increases and often reaches a considerable amount, Behrends found a pressure of 14.6 atmospheres at the bottom of a borehole, 4 metres in depth, in the newly-opened section of the No. 13 seam at the Hibernia Colliery in Gelsenkirchen, Westphalia. In some very deep Belgian pits, pressures of 20 to 23 atmospheres have been recorded and as high as 42.5 atmospheres in a borehole in unworked coal.

Wabner says that the rule seems to be that the greater the depth of a seam below the surface, and the more effectively it is shut off by impenetrable cover rock, the higher will be the pressure of the imprisoned gas, and consequently the more violent the outrush of gas when the seam is tapped, but the longer it is worked and the greater the number of galleries and other openings made therein, the more will the initial pressure and outflow diminish in the course of time until finally the latter ceases altogether or diminishes to an imperceptible quantity.

It follows naturally, therefore, that more gas is thus encountered in opening out a new section of a coal mine than when the same has been worked and has long been traversed by headings. Wabner thinks that there is thus evidently an analogy between the occurrence of fire damp and pit water, for in both cases the initial outflow is the greatest, diminishing in a short time as the drying progresses.

It should be remembered that when CH_4 combines with oxygen it is decomposed into CO_2 (carbon dioxide) and H_2O (water). Thus the progressive absorption of the oxygen by this CH_4 either within or outside of the coal structure would tend to a progressive increase in the amount of water formed.

Gas as a Comminuter of Coal

According to Wabner (p. 27) the volume of gas can be reduced (1) by the ventilating current, (2) by limiting the output of coal, and (3) more especially by regulating the preliminary work of opening up new sections of the pit. In connection with the last precaution he mentions the following facts:—

"Since under ordinary conditions the gas intimately permeates the coal and fills its pores at a higher or lower pressure, the gas also influences the coherence and firmness of the seam, and under certain circumstances may make the coal friable and brittle. For this reason fiery bituminous coal beds frequently yield nothing but small coal; and occasionally this factor becomes so prominent as to make coal-getting dangerous, especially in sloping seams. This evil can be counteracted by tapping the bed with bore-holes before commencing to win coal from the face: in this way the coal is rendered more solid and resistant. More especially has this contingency to be taken into consideration when two

gassy seams are united in close juxtaposition. In such event the coal could undoubtedly be more easily won by working both seams simultaneously, and only small coal would be obtained; whereas by working one seam before the other, an opportunity is afforded for the gas in the second one to escape, and the coal from this will then be more solid and furnish a larger proportion of lumps."

In the Report of the British Royal Commission in 1886 on Accidents in Mines, it is said (p. 112) that "The experiments we have made on the pressure of firedamp in plugged bore holes, in coal, a pressure amounting to upwards of 400 pounds on the square inch, have thrown much light upon the occurrence of sudden outbursts of gas. The boring of holes upward or downward has been successfully tried as a means of avoiding such outbursts.

"It is almost impossible to account for many of the accidents which have occurred in well-managed mines, some of which have originated in the main-intake airways, except upon the supposition that gas has suddenly invaded the workings from the adjacent strata. Sudden outbursts of large quantities of gas, accompanied by violent disruption of the floor, roof or coal, are fortunately rare, but smaller incursions of gas, accompanied by falls of roof, or even without any apparent displacement of strata, are comparatively frequent."

The Commission believed that these abnormal discharges of gas might be successfully met by ample ventilation, good discipline and efficient lamps. While they recognized that variations of atmospheric pressure exert an influence for the escape of gases which have accumulated in cavities, and possibly to a slight extent on that of gases emitted directly from the coal, they questioned the wisdom of placing entire reliance on meteorological warnings such as the fall of the barometer. In their opinion, safety must also be ensured by unceasing vigilance on the part of the officials and workmen in the mine, irrespective of such warnings.

Emission of Methane

The experiments of Rollin T. Chamberlin and others* have shown amongst other facts that methane is given off by all coal and is quantitatively by far the most important gas which it evolves usually amounting to from 80 to 95 per cent. of all the gas which is emitted but in some cases it reached 98 per cent. It is significant that it was found that anthracite coal yielded the highest per cent. of methane in the gas liberated, but that low atmospheric pressure which aided the escape of gas from bituminous coal had less effect on the liberation of gas from anthracite.

Other facts established by experiments are that finely powdered fresh coal gives off more methane in a vacuum than the same amount of lump coal subjected to the same conditions and that the finer the coal the more rapidly and completely was the gas liberated in a given time.

These facts seem to indicate clearly that the increased facilities for the elimination of methane that are acquired by coal with each increase in the fineness of pulverization, must also increase the liability to and destructiveness of a mine explosion after ignition and in direct proportion to the degree of the comminution of the combustible coal. That methane and other gases are constantly exhaled by the coal is shown by the fact established by experiment that fresh dust yields five times as much combustible gas as old dust and only one-third as much noncombustible gas. Age apparently tends to lessen the explosive tendencies of coal dust. In its last analysis, therefore, coal dust must be regarded as a secondary predisposing cause to mine explosions, the primary predisposing cause being the methane the undue accumulation of which is favored by the dusty form of coal. Proper ventilation to give a constant outlet to this gas, and the application of lime or rock dust to offset the uplifting and gas-extracting effects of low pressure on the comminuted coal would seem to be the easiest and least dangerous methods of dealing with the dust problem. The material thus treated might be later collected and converted into some kind of building material. It would seem better still if after condensation the dust could be conveyed to some reservoir where pressure or chemicals could be applied to condense the dust into combustible briquets of coal.

Coal Mine Ventilating Equipment

By W. M. Weigel *

The distinguishing features of several forms of modern steel-plate fans are discussed, as are also two types of high-speed fans, a comparatively recent development in the line of mine ventilating equipment. This is the fifth article of a series dealing with mechanical ventilators.

*Associate Professor of Mining, Pennsylvania State College, State College, Penn.

As far as the construction of the wheel and position of the blades are concerned the simplest form of centrifugal mine fan is that made by the Buffalo Forge Co. Fig. 6 shows an elevation and plan of an installation of one of these fans for the Madoc Coal & Mining Co., Glouster, Ohio. This is arranged to operate either blowing or exhausting. The blades of this make of fan, usually 8 or 10 in number, are of heavy steel plate and are placed in a radial position with a slight backward curve at the tips only. Conical side plates inclose the sides of the wheel from the periphery of the inlet to the tips of the blades.

The blades extend inward from the periphery of the inlet for a distance equal to about one-fifth of their length, the outside corners being cut off as shown in the illustration. They are supported by the tee-iron arms of the spiders of which there are two and sometimes three. These arms are cast into the hubs of the spiders, making a particularly rigid form of construction. The shaft is supported in bearings hung on trunnions to prevent heating or wear from any deflection of the shaft. This, as well as other types of fans, often have the bearings water jacketed on the lower side to prevent undue heating.

The diameter of the inlet is about ⅔ the diameter of the fan wheel. Distinguishing features of this form of fan are: the large clearance between the fan and casing, especially at the cutoff, and the slight rate of increase in the radius of the spiral until the discharge opening is reached. The fan shown in Fig. 6 has an inlet on one side only, but these fans are built with two inlets if necessary.

Jeffrey Fan

Like other modern mine fans, the Jeffrey type is constructed entirely of steel plate except for that portion of the housing included within the foundation. These fans are built with either a single or double inlet. As illustrated in Fig. 4, the double-inlet form has a central disk of the same diameter as the wheel. The outer sides of the blades are fastened to annular side plates or cheeks, the inner diameters of which are the same as the diameter of the inlet openings in the casing. These annular plates are braced and held rigid by round iron rods which spring from a small hub on the shaft and offer practically no obstruction to the inflow of air. In the single-inlet type of fan, the solid driving disk forms the side plate of the wheel on the side opposite to the inlet.

100	1.6	4400	2.4	66%
125	2.4	5500	4.0	60%
150	3 4	6600	5.7	60%

HORSEPOWER IN AIR AND MECHANICAL EFFICIENCY

Rev. per Min. of Fan	Water Gage	Cu.Ft. Air per Min.	Hp. in Air Delivered	Indicated Horsepower	Mechanical Efficiency
75	0.9	80,000	11.36	13.6	83.5%
100	1.6	105,000	26.5	33.2	80.0%
125	2.4	125,000	47.35	62.4	75.8%
150	3.4	160,000	85.95	117.8	73.0%

The distinctive feature of these fans is the number and shape of the blades. Referring to Fig. 5, it is seen that there are eight main wings or blades extending from the periphery of the wheel into the inlet space for about ⅓ of the distance from the circumference of the inlet to the center. Starting at the inner end, these blades slope backward from the direction of rotation to a point just within the circumference of the inlet and then curve forward in a circular arc to the periphery; so that at the tips, their course is forward from a radial line, in the direction of rotation.

Half way between the main wings, is another set of a length equal to that of the curved portion of the main blades and curved to the same radius. Between these and the main blades is still another set with a length about one-half that of the second set and curved to a shorter radius. In the angle between the inner ends of the main blades and the circumference of the inlet are located conical sheet-steel scoops projecting into the inlet beyond the side line of the fan wheel. It is claimed that these strengthen the action of the fan and prevent gushing of air back into the inlet.

The diameter of the inlet is about 4/7 of the diameter of the wheel. The clear-

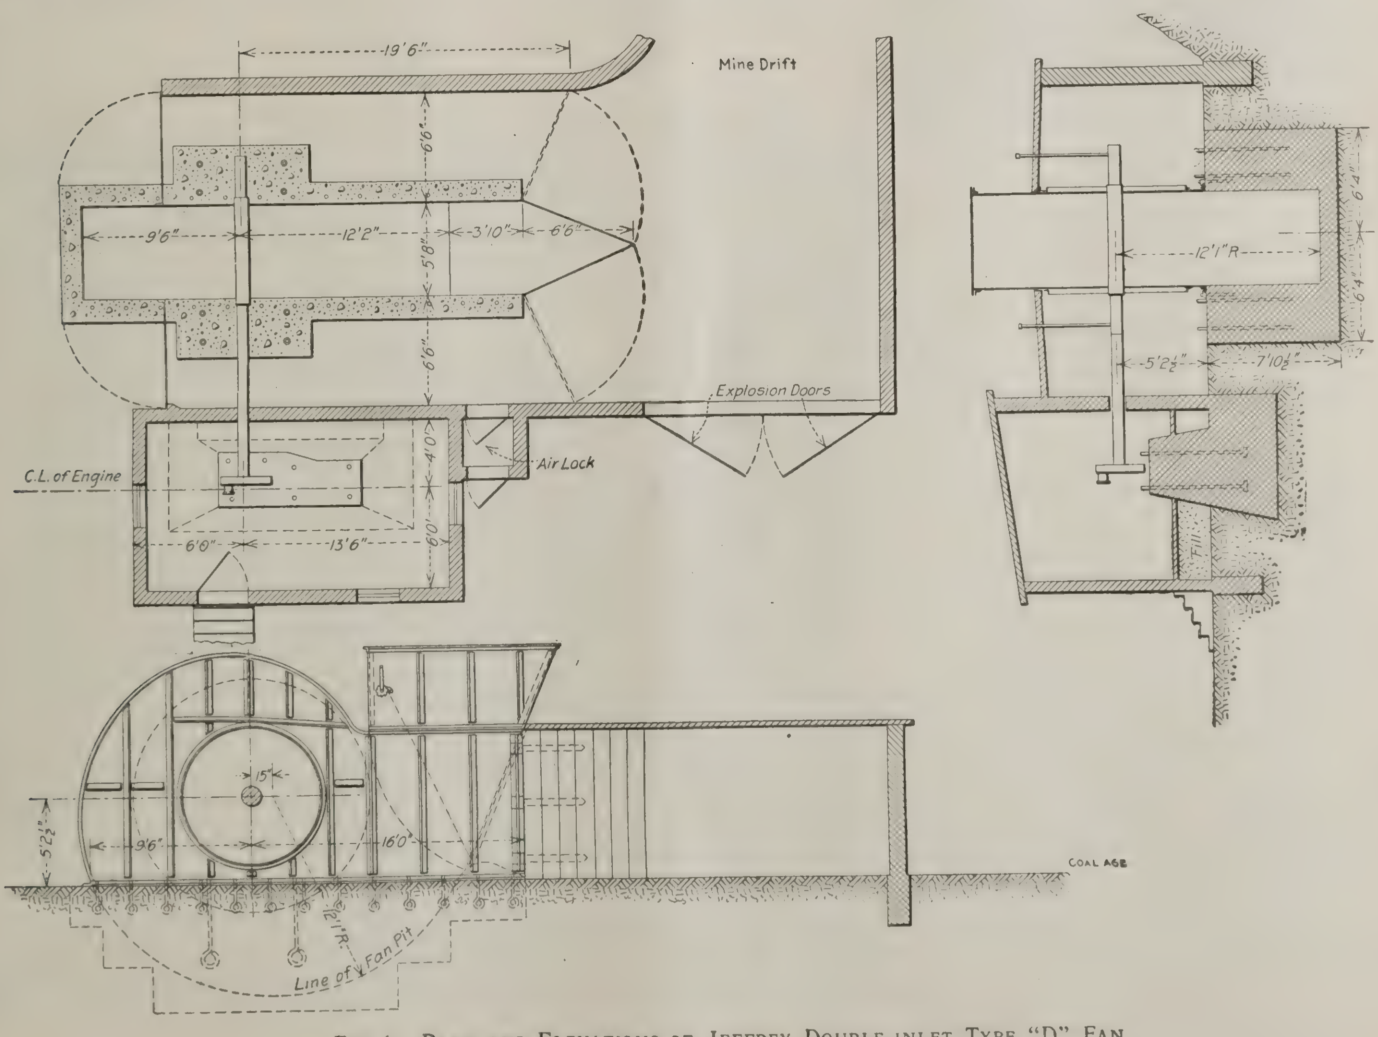

FIG. 1. PLAN AND ELEVATIONS OF JEFFREY DOUBLE-INLET TYPE "D" FAN

ance at the cutoff is small and the spiral casing has a rapidly increasing radius. Disregarding the long main blades and scoops, this form of fan closely resembles the multivane fans in the number and forward curvature of its blades.

Fig. 1 shows the setting for a double-inlet Jeffrey fan, arranged primarily for exhausting but so designed that it may be converted into a blower.

In Table 1 are given the results of a test, of a 14-ft. diameter by 4 ft. 6 in. wide, single-inlet fan, installed for the New Pittsburg Coal Co., at Murray City, Ohio.

High-speed Fans

The term "high-speed fan" refers to fans operating at relatively high rotative speed rather than at high peripheral speed, and is used to distinguish a class of fans which has been developed within

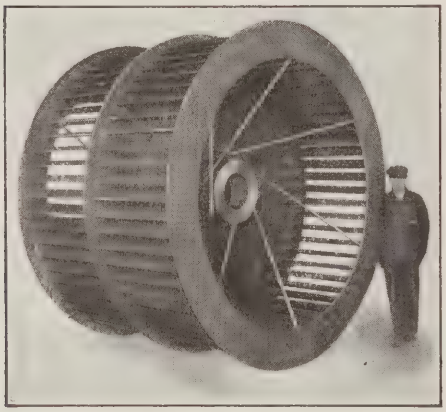

Fig. 2. "Sirocco" Fan Wheel

the past few years and only recently has been applied to mine ventilation to any extent. High-speed fans have many excellent features to recommend them and a number of successful installations have been made in various sections of the country, although some mining engineers still hold them in disfavor.

These fans are distinguished by the large diameter of the inlet as compared with the diameter of wheel, the radial length of the vanes or blades being only from $\frac{1}{8}$ to $\frac{1}{16}$ of the wheel diameter. A great number of vanes are employed, usually from 42 to 64. The fans are further distinguished by having their blades curved concavely toward the direction of rotation. The casing expands rapidly and gives a large discharge area at the point of cutoff.

The main points of advantage of this type of fan are low first cost of fan and installation, small space requirement, good mechanical efficiency and volumetric capacity, suitability to developing high-water gages, and, on account of the high rotative speeds, facility of direct connection to electric motors.

Sirocco Fan

One of the first high-speed types to be developed was the Sirocco fan. Fig. 2 shows the general construction of the wheel or runner of a double-inlet fan of this variety. A single-inlet type is also made. The central or driving disk is of heavy steel plate, springing from a cast hub, which in the double-inlet form is made in halves. The outer surface of this central disk is conoidal in form in order to prevent eddying of the air as it enters the wheel. The 64 blades are of pressed steel and are supported between the central disk and the front plates, or inlet circles, which are also made of heavy steel plate. The inlet faces of the wheel are stayed by tie-rods from the hub. This arrangement leaves the inlet practically unobstructed. Fig. 3 shows a Sirocco fan in service at Shaft No. 35 of the Berwind-White Coal Mining Co., Windber, Penn., and illustrates the adaptability of this type of fan to direct electric drive. This installation

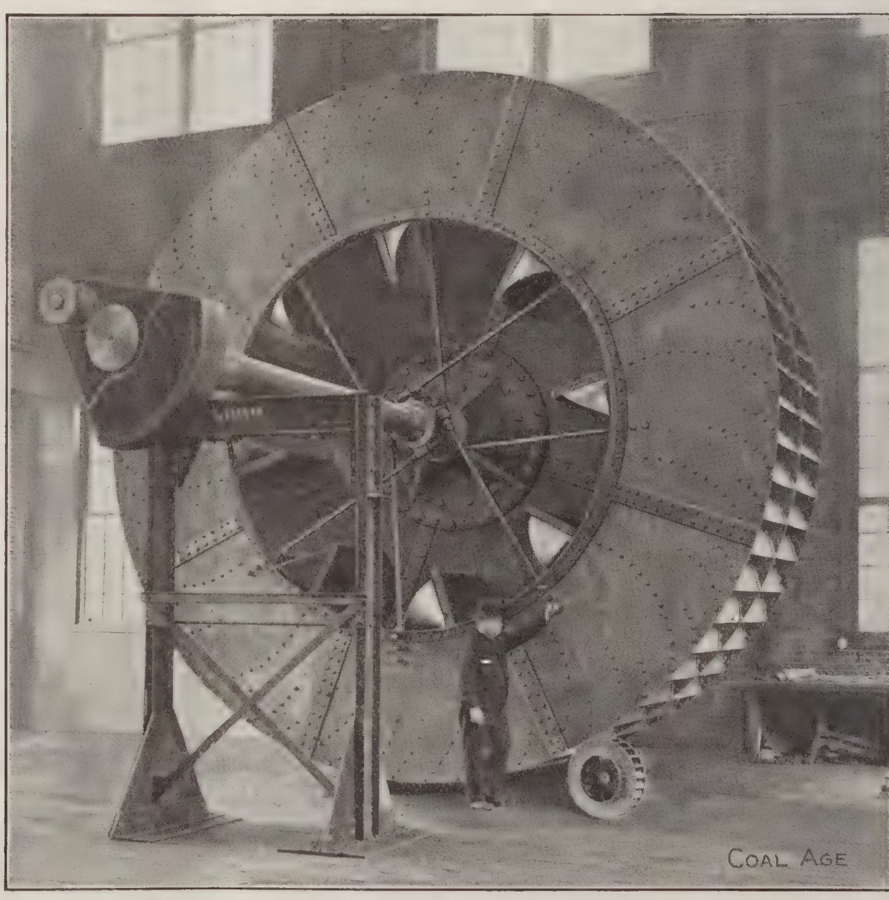

Fig. 4. Jeffrey Double-inlet Fan Wheel

delivered 315,000 cu.ft. of air per minute at 5.6 in. water gage while running at 252 r.p.m. The wheel is 108 in. diameter by 72 in. wide. The small size of the fan house is at once noticeable.

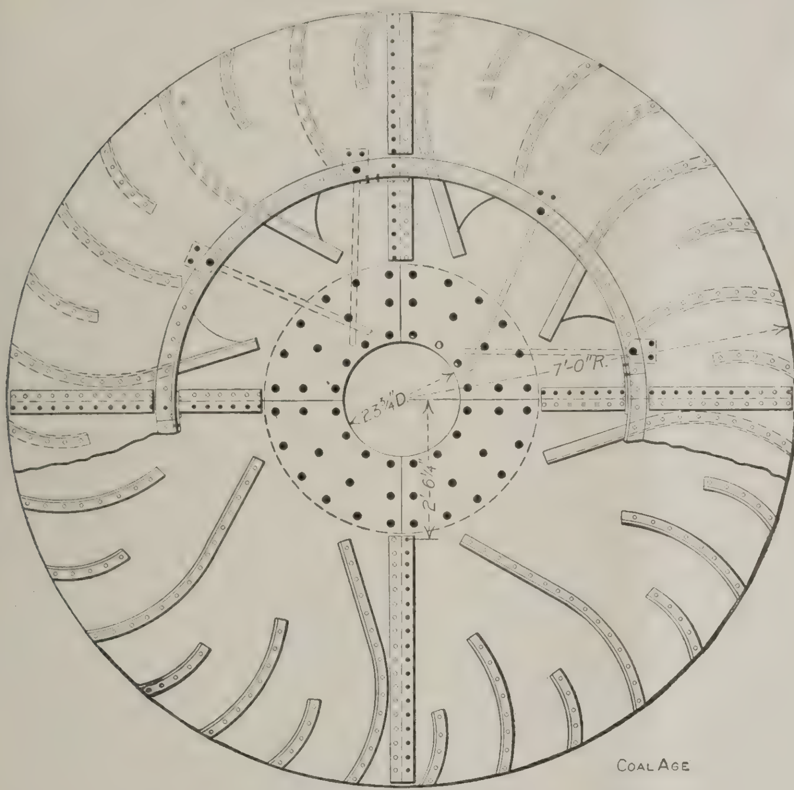

Fig. 5. Details of Jeffry 14-ft. Fan Wheel

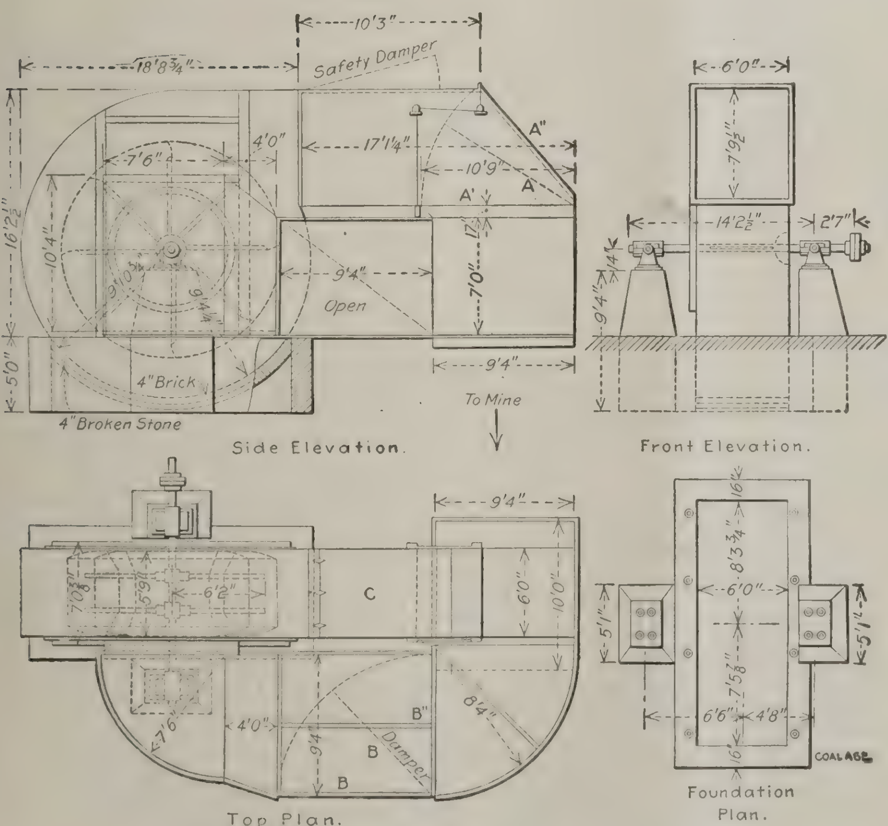

Fig. 6. Buffalo Forge Co. Fan for Modoc Coal Co.

The Sturtevant Multi-vane Fan

The Sturtevant multi-vane fan is quite similar to the Sirocco fan in construction and general details, the main difference being that the vanes, in addition to being curved concavely in the direction of rotation, are also corrugated or spooned across the face in a radial direction. This form of vane is claimed by the manufacturers to prevent the air from slipping along the blades in a direction parallel to the axis of the wheel and thus increases the volumetric efficiency of the fan.

Cost of Anthracite Co

Anthracite coal was at one time an important factor in blast-furnace practice, but for this purpose it has been almost entirely supplanted by coke made from bituminous coal, according to E. W. Parker, coal statistician of the U. S. Geological Survey, in an advance chapter from "Mineral Resources for 1910," lately issued. The principal future demand for anthracite will be restricted largely to domestic trade, for which the sizes known as furnace, egg, stove, chestnut and pea are required.

The breaking down of the lump coal, which was formerly a marketable product, for the preparation of the domestic sizes, results in an increased proportion of the small or undesirable sizes, all of which are sold at less than the cost of production. The proportion of these small sizes has increased from 23.1 per cent. in 1890 to 41.6 per cent. in 1910, while the proportion of sizes larger than pea coal, or what may be termed the profitable sizes, has decreased from 77 to 58.4 per cent.

The price of anthracite coal at the mines in 1910 averaged $2.13 per long ton. All the profits on the mining operations must be obtained from the prepared domestic sizes, for the revenue obtained from the smaller sizes, which are sold largely in competition with bituminous coal for steaming purposes, serves only to reduce the cost of the domestic sizes. The conditions under which the anthracite mines are operated, says Mr. Parker, the greater depths to which the workings are carried, the consequent increased expense of mining, and the increasing cost of labor all contribute to make anthracite fuel more and more a luxury. No hope is held out to the consumer that anthracite will, in the future, be sold at lower prices than those which prevail today; on the other hand, there is every reason to believe that prices must advance in accordance with the increasing cost of production. It is only by reason of economical administration that prices are not higher than they are.

During recent years the anthracite operators have adopted the policy of making an allowance of 50c. per ton from circular prices for domestic coal purchased in April of each year, with an advance of 10c. for each succeeding month until the schedule prices are restored in September. This has had a salutary effect in steadying the trade and permits the mines to be operated more regularly.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Gob Fires in Yorkshire, England

The following is an abstract of a statement made by W. H. Pickering, one of the English mining inspectors, in the course of an inquiry of the British Home Office into the gas explosion at the Jammage Pit, North Staffordshire. Mr. Pickering was asked to present an account of mine fires in the neighboring South Yorkshire coal field.

It appears that the more fiery coal seams in Yorkshire, that is, those which give out the greater amount of gas, are not those which are most actively troubled with mine fires. However, the Barnsley seam, in the Doncaster neighborhood, is an exception to that general rule. The coal lies deep, the deepest shaft reaching the bed at a depth of 2715 ft. A typical section shows a seam 9 ft. 2 in. thick, including a parting of dirt 6 in. thick. In this one seam are contained five distinct beds; one of these is a hard coal suitable for steam, 2 ft. 2 in. thick, and the rest is soft house coal. The seam is very gaseous; outbursts of firedamp are common, and the gas can always be found. A recent analysis showed nearly 2½ per cent., in air currents of 88,000 cu.ft. per minute.

The men have to be withdrawn from time to time, owing to the presence of gas in dangerous quantities. An inferior fireclay underlies the seam, and the roof is, as a rule, a tender shale. The seam is worked on the advancing longwall system, the gate roads of which are from 40 to 50 yd. apart. For commercial reasons, a large percentage of the coal is not sent out of the pit; the harder coal, being very valuable, is carefully extracted, and the bottom, or soft coal, is systematically worked with it. Most of the top soft coal is lost. In some cases no attempt is made to work it, the only part recovered being any large lumps produced when the gate roads are ripped. At these pits, the slack made in the face is also thrown into the waste, and the total loss in some of the new mines is over 40 per cent. of the seam. The roadways are troublesome to keep in order, and large quantities of dirt are moved during each repairing shift. As much as possible is stowed in the gob, but frequently such stowage is impracticable. Every effort is made to withdraw the timber from the gob and from the abandoned roadways.

Fighting Gob Fires

As a rule symptoms of heating are detected in the early stages, but at times the fires reach the burning point before they are suspected. Fires occur in the gob and die out without the management knowing anything about them. Their ashes are sometimes found when roads are being driven through old wastes. It will be readily understood that in the advancing longwall system of working, the difficulty of isolating fires by dams is almost insuperable. The strata are so broken up that gas-tight dams could not be built. The fires are dug out at all cost, even in cases where stoppings might be practicable. The operation of digging out a gob fire consists of driving headings into the fire area and extracting the burning or heated material, and sometimes packing the space with sand. Water jets under great pressure are used to quench the fire or cool the heated strata. It is quite simple on paper, but in practice is very difficult and dangerous. The heat is often so great that the men can only work for a few minutes at a time, and the ventilation must be arranged so no firedamp will pass over the fire. The work is costly.

Nevertheless, digging out is far safer and more economical in the long run than stopping. When a fire area has been dug out and the spaces packed with sand or otherwise effectively treated, it usually gives no more trouble. If a fire is stopped off it may annoy the management for years, and noxious gases from it may find their way into the mine workings.

English Ventilation Laws

In an address on "Duties and Qualifications of the Deputy and Fireman as Defined by the new Regulations," delivered at Ashby-de-la-Zouch on Jan. 6, G. H. Winstanley remarked as follows:

A ventilating current may have a volume of as much as 250,000 cu.ft. per minute. This is quite an ordinary quantity in the Lancashire field. In the course of 24 hours, the total weight of air passed through such a mine would amount to no less than 12,000 tons. Such a volume of air is capable of diluting, within the limits provided for in the Act, a volume of gas which would suffice for the needs of a large town.

The moisture present in the mine air should not be permitted to become excessive. The limit of wet-bulb temperature should certainly not be higher than 75, and 70 would be a better limit to adopt. That circumstance virtually disposes of the watering of deep mines as a safeguard against the dangers of coal dust. It is important that deputies and firemen should understand those points, because I have found, in more than one instance, that miners regarded high temperature as a definite and unmistakable proof of the presence of gas.

OXYGEN CONTENT NOT TO FALL BELOW 19 PER CENT.

I feel sure that the new standard of 19 per cent. of oxygen as a minimum presence of that constituent in mine air is by no means difficult to attain. In 1907, in connection with the investigations of the Royal Commission, Dr. Cadman and Mr. Whalley made careful inspections of some 40 selected collieries where either abnormal difficulties were met with, or where the ventilation was considered as capable of improvement. In 11 of these cases only was the ventilation found to be below the standard now established, and all of those, I believe, were cases where there should have been no difficulty in securing better ventilation. It is a curious but easily explained circumstance that those collieries which are easiest to ventilate have usually the impurest air.

In many cases there is an impression that ventilation only becomes important where inflammable gas has to be considered; consequently, in mines which are supposed to be free from methane the ventilation is often neglected.

On the other hand, mines in which inflammable gas is given off somewhat freely must be ventilated with such a volume of air as insures the oxygen percentage being kept well above the lower limit now permitted. For example, it is easy to show that to lower the oxygen percentage to 19 by the mere admixture of inflammable gas would require the latter to be in the proportion of nearly 10 per cent. Similarly, except perhaps in very rare cases of mines which give off carbon dioxide, the new standard of 1¼ per cent. of that gas (the maximum now, by law, permissible) cannot be regarded as one difficult of attainment. A lamp, however, affords no reliable guide either to the oxygen or the carbon dioxide standard. If the lamp is extinguished, it is certain the percentage of oxygen, demanded by the regulations, is not present, but we need to be able to determine when the percentages approach the limit set by the legislative provisions.

DETERMINATION OF OXYGEN

For open-light mines the tube and taper apparatus of Dr. Haldane may be used to determine the oxygen and carbon dioxide percentage, but in safety lamp mines it may, as a rule, be assumed that the oxygen and carbon dioxide percentage will be kept within the regulations by proportioning the ventilation properly to dilute the inflammable gas. In mines where safety lamps are used and inflammable gas is given off by the coal, the only method of determining the percentage of oxygen and carbon dioxide is by means of the analysis of samples.

COAL AGE

The Jammage Mine Fire

It is so customary to regard mine fires as the outcome of burning gas, explosions or of inflamed brattices, whether of cloth or wood, that the history of the Jammage mine fire in England should serve to recall those less general conditions to which the lignite fields of North America are especially subject.

On Nov. 25 of the past year, a fire broke out in the gob of a mine generating gas. The area was worked by longwall, but the extraction of coal was not complete. Because the mine was developed irregularly, due to the contortions of the strata, there were more than two approaches to the district where the fire occurred, and it was necessary to confine the conflagration by the building of several stoppings. Moreover, as the area mined was not in panels surrounded by pillars of coal, the gob to be shut off was large.

It was some time before the fire made itself apparent. A sulphur smell is alleged to have appeared early on Thursday morning. A pillar of the mine was found to be heated on Friday, and at 7 a.m. that day all the men were removed from the mine except those that were to close off the fire.

Unfortunately, the colliery officials decided to build their stoppings once for all of stone and dirt, and made no effort to keep air from the fire by the use of temporary brattices. It must be remembered that they appear to have expected an explosion and desired to assure themselves that when it occurred, only that part of the mine which was not working would be involved. The stoppings for some reason took 27 hours to build, and during that time the coal must have inflamed and the gas exploded. The damage done by the explosion was inconsiderable, nevertheless, six men were killed by the resulting gases.

It was suggested that the fire should have been extinguished by water. Those on the ground were best able to judge, but surely wood brattices could have been more rapidly constructed than brick stoppings, such as the experts suggested in the Home Office investigation. This would have shut off the air within an hour of the time when the need for closing up the fire area was recognized.

The objection to a brick stopping is the long time required for the maturing of the cement in the joints. It is slower in erection than wood, and slower to become efficient than a stone filling. Nothing but a rock wall should have been ultimately relied upon, but it does appear that the first protection should have been secured by the use of timber.

Efficiency

There is, in any language, no word that spells SUCCESS as surely and as plainly as *efficiency*. Thrift is a near neighbor to efficiency, the latter is indeed the outgrowth of the former; for what man can become efficient who has not learned the principles of thrift, or who is thrifty without proving his efficiency?

Success is the crowning sheaf—the certain award of efficient toil. That man is efficient as a worker who can produce results; or, in common terms, "deliver the goods." Such men are needed today in coal mining more than in any other trade or calling.

It requires no argument to demonstrate the fact that the industry of coal mining is peculiarly environed. It is subject to limitations so proscribed as to demand the exercise of the strictest economy in operation. A living wage for the miner, a reasonable profit for the operator, and a price to the consumer that will place this great necessity of life within the reach of all.

The problems of coal mining would be less difficult of solution if coal could be classed as a luxury. The demand for wage increase could then be met, if necessity required, by a corresponding increase in the cost to the consumer. The luxuries of life will always bring whatever price their production and a fair business profit demand. Only those whose means will allow them to pay the price

can have the luxury; others must do without.

But we are face to face with the fact that coal is not a *luxury,* to be had if one possesses ample means; it is a necessity of life that *all*, rich and poor alike, require and must have. It is this fact that fixes the upper limit in the coal mining problem. It is a hard, cold fact, as cold as the cheerless fireside without fuel in December.

The high cost of living may create a demand for wage increase. What is the coal operator to do in that event? The margin between the *living wage* and the *living price* is so narrow that the risk does not warrant investment. If there is not soon found some way out, capital will seek other more lucrative fields.

This is only one of the many problems confronting the coal operator. There are others as serious and as threatening, which we have not space to treat as they should be treated, now. What is the remedy? This is the question that operators in all coal fields are asking today.

There is but one answer as far as the mining of coal is concerned. There must be greater efficiency. This does not mean more work or longer hours, for the same pay. That would not spell *efficiency*. It means less waste of time and material in and about the mine; more system in the planning and execution of work; more devotion to the work of mining and less sympathy for the idlers whose only thought and desire is apparently to give less and demand more. No honest worker can uphold such a creed; but all must recognize that the only sound doctrine is *"a day's work for a day's pay."* Let this be written on the heart of every mining man, whether he be mine official or miner; and let each strive to prove himself more efficient in the work he has to do.

Methane in Coal Dust Explosions

Under the above caption in the present number of COAL AGE, Mr. Wilbur summarizes the results of his inquiries and researches into the origin of mine explosions. The publishing of this paper should not be construed as an endorsement of all Mr. Wilbur's conclusions. For any such detailed approval, he must look to others, to the hundreds who in face of all proof to the contrary still contend that coal dust will not explode unless ignited by methane. Such statements are never backed by any careful reasoning. The usual method is to face the issue by a personal asseveration, by the *ipse dixit* or "take it from me" of the asseverator. Signs of such a standpoint are found in Mr. Wilbur's argument, but in his paper he makes a plea for the reasonableness of his view, so that we feel he would not compel us to accept it on the mere force of his authority.

But for what imaginable purpose have the experiments at Pittsburgh, Bruceton, Altofts, Liévin, Frameries, Gelsenkirchen and Babitz been conducted at so much unnecessary trouble and expense if we, following Mr. Wilbur, are complacently to avoid quoting the results there obtained and are to draw on the unexperimental dicta and baseless imaginings of a decade or two ago?

He quotes the well-known Chamberlin monograph, as far as quotation will serve his purpose, carefully showing how much free methane can be liberated by crushing and carefully abstaining from showing how slowly, we had almost said laboriously the coal liberates methane thereafter. Even so far as Mr. Chamberlin is quoted, with all the handicaps of an *ex-parte* quotation, we cannot see that the Bureau of Mines and its explosions' expert, Mr. Rice, are hoisted on their own petard. If Mr. Wilbur had quoted the further remarks of Mr. Chamberlin, he would have arrived at the conclusion that coal after crushing ceased to deliver gas with the rapidity with which it is liberated when crushed.

There is no reason to suppose that every particle of coal dust is surrounded by a methanized gaseous pellicle, or that the mine in general is made explosive by the emission of methane from the floating or the resting dust. In the first six weeks coal crushed in air and immediately placed in a vacuum only developed 0.0538 per cent. of its whole volume of methane per hour. In the following ten weeks the percentage fell to 0.0101 per cent. and in the ten weeks succeeding, it still further fell to 0.0035 per cent. As the air in the mine is changed about every half hour, these figures might well be divided by two.

Even if the mine were packed full of dust, the hourly percentage of gas it would generate would nevertheless be inappreciable. We must remember that Chamberlin was dealing with a coal of high methane content for the dust just described came from Monongah. Dust from non-gaseous mines, as we term them, would have lower values of methane emission, especially when newly pulverized.

But this method of arguing may be fortified by still another. The Bureau of Mines, in its Pittsburgh gallery, has obtained ignition and propagation when using only two pounds of dust and no gas. This gave a dust density of 25.3 grams per cu.m. According to Mr. Chamberlin's figures, the coal, before crushing, would have held 2.67 cu.cm. of free gas, of which 39.65 per cent. by weight would have been methane. Careful estimation shows that had the coal been broken into bottles in vacuo and these bottles sealed and conveyed to the confined gallery, they would have added to the air in that gallery on release only 0.0000808 per cent. of methane. Judge therefore how little methane must have entered the gallery when two pounds of dust comminuted in air, were blown into it to circulate at a pressure not less than atmospheric.

In conclusion it may be added that modern research has proved that the explosion of methane in an atmosphere insufficient for complete combustion results in the generation of carbon monoxide, thus contradicting the results of Dr. Brookman of Bochum whom Mr. Wilbur quotes in his article ,with apparent approval.

The question has been raised whether pure coal dust on a safety lamp can be exploded from the lamp. Few persons have met with this experience in practice, and it is probable that the question has been given thought by only a small number of coal men; however, under certain conditions, it is possible to get such an explosion experimentally. A mining man in South Wales relates an instance of a safety lamp that had been continuously in use underground for some hours and on the gauze of which coal dust had collected; he experienced a slight explosion in the lamp, followed by a second and much more violent explosion immediately afterward. The second explosion was believed to be due to the shock of the first explosion precipitating more coal dust into the flame.

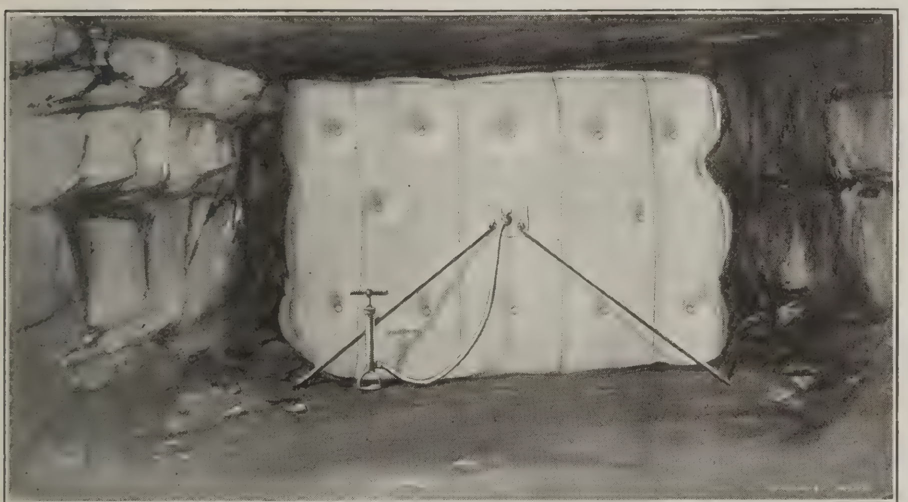
Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Sealing off a Mine Fire

(Continued from Feb. 10)

Letter No. 24—I think that when a fire occurs at the end of an entry, the first thing to do is to diminish the circulation of the air past the fire. Under ordinary conditions, it would seem easier to build a wall on the intake side first; then, by reversing the circulation, the smoke could be forced back so that the fire would be confined to the smallest possible area. This would reduce the supply of air, walled in with the fire, to a minimum. To accomplish this, it is best to set the first stopping of brattice cloth or lumber far enough ahead of the last open crosscut to permit of the building of a permanent wall between the crosscut and the temporary brattice.



An Air Mattress for Confining Fires

In some gassy mines, square air mattresses, blown up by a hand air pump, as in the illustration, are utilized to make the first stopping. With these provided, in about four minutes the circulation can be stopped and the sealed-off territory reduced to a much smaller limit than could be done if the men had to build more elaborate stoppings in the smoke.

I inclose a rough sketch of such a pneumatic curtain. It can be folded up and quickly carried to the place affected. The mattress is 14 in. thick, and in its other dimensions is the size of the heading it is intended to fill. A central plate, with a pipe affixed thereto, permits the attachment of a rubber hose, through which the air can be pumped into the mattress for purposes of inflation. The bag stopping is supported temporarily by four legs, two of which are hinged to the central plate just mentioned, and two to a corresponding plate at the rear. The front and back walls of the mattresses are prevented from bulging outward under the air pressure by the use of ribbon stays. When the bag is properly inflated, it fits and adheres to all the various irregularities of the outline of the heading, and is prevented from forming itself into the shape of a balloon by the restraining force of the stays, just mentioned.

Carl Scholz,
Vice-Pres. and Gen'l. Mgr., Consolidated Indiana Coal Co.
Chicago, Ill.

Letter No. 25—There are mine fires and mine fires; there are men of experience, men of practice, men of theory; there are numberless and varied degrees and conditions in mines. The successful mining man today is a student of these conditions.

From the very nature of the case mine fires are dangerous; and the fire that has assumed proportions beyond control requires not only knowledge and experience, but, more than all, nerve, tact, a clear head, an instant grasp of all the conditions, and the ability to act promptly and with fortitude.

That such prompt, decisive, intelligent action at the Cherry mine, in the first stages of that terrible disaster, would have saved a large proportion, if not all, of the 256 lives then sacrificed, no practical mining man will deny.

In the present discussion it is proper to ask or assume, what are the conditions of environment. No one will deny the practical impossibility of approaching sufficiently close to a raging fire, on the return side, to enable a stopping to be built in the return airway for the purpose of cutting off the circulation of air and confining the fire. The same is true where the return airway is completely filled with dense volumes of smoke and gases; unless, of course, the work can be done by the use of breathing apparatus.

On the other hand, no intelligent mining man will attempt to deny that whenever it is possible to get in and erect the first stopping on the return airway, and later close the intake, this is the thing to do. "Why?" Because the stopping erected in *any* portion of an airway will block the circulation of air. The stopping built on the return is just as effective in cutting off the flow of air past the fire as a stopping built on the intake.

The erection of the first stopping on the return, however, possesses the additional advantage that it confines the products of the combustion to the area of the fire. Not only do the expanding gases force back the air and, to a large extent, prevent it from reaching the fire; but the carbon dioxide (CO_2) produced by the combustion, renders the gases generated nonexplosive.

Again, suppose the first stopping is erected on the intake airway, under conditions that would have permitted its erection on the return. It is true the fresh air is cut off from the fire; but a very explosive mixture begins at once to form behind the stopping, in the region of the fire. It may happen that the sudden extinction of the flame of the fire, by the cutting off of the direct access of the air, will create a depression within the fire zone that will cause some air to enter the return openings before these can be closed. Now, while building the return stoppings under these conditions, the explosion of gas, or dust, in the case of a roof-fall within the area, is most liable to occur. This is what has often happened when the intake stoppings have been erected first and the return stoppings last.

It is almost idle to attempt to lay down rules or form a plan of procedure without having before us a plan showing the location of the fire, the course of the air current and the position of all crosscuts, stoppings and doors affecting the

circulation. But in general it may be stated the air current should be short-circuited and, as far as possible, diverted from the fire by the erection of temporary canvas brattices. By the partial removal of one or two stoppings and the erection of a line of brattice, it may be possible in many cases to conduct sufficient air past the fire to the place where the return stopping must be built. In some cases a canvas sheet can be arranged in the return, ahead of the stopping to be erected, so as to throw the smoke and gases over the men engaged in the work. When the stopping is built nearly to the roof, this canvas must be removed and the work finished. The men in the meantime receive a sufficient supply of fresh air from a crosscut close to the stopping being built. The erection of the intake stoppings is then easily accomplished. In all cases it is necessary for the mine foreman in charge to exercise the utmost ingenuity, judgment and skill.

J. T. Beard.

New York, Feb. 6, 1912.

Letter No. 26—I have read with interest the opinions on fighting mine fires, and I believe that since there is no established standard of occurrence for these fires that there cannot, accordingly, be any standard method for fighting them. The method of attack is determined entirely by local conditions, but must be decided upon quickly, since what otherwise may be a disastrous fire might be easily controlled if caught in the incipient stage.

I believe I have had an unusually bitter experience on an exceptionally discouraging piece of work of this character. This fire occurred in April, 1900, in the thin-vein district not far from Pittsburg; it originated in an electric pump house which consisted of a wood-stopping on each side of the pump, between the intake and return airways, somewhat over a mile from the mine entrance.

One man was known to be behind the fire, and desperate chances were taken to effect his rescue. We tried to conduct a narrow airway along the rib so we could get near enough to force water on the fire. The roof had fallen for about 6 ft. above the coal along this section; so to get a support for our brattice we leaned rails, about 7 ft. long against the sides diagonally and pulled canvas over them. Only a few feet at a time could be gained, the smoke having backed up some 300 ft. against an air current of about 20,000 cu.ft. per minute, and the work was particularly trying, for in addition to the heavy smoke, the roof was continually falling. When we had reached a point about 100 ft. from the fire, a heavy fall occurred behind us, breaking down the brattice and cutting off our air, with the result that we were only able to escape with our lives.

A second attempt was made by nailing boards in the shape of an inverted L, to which the brattice cloth was attached and carried in. By this means we were successful in getting to within 25 ft. of the fire, when our brattice took fire and was consumed before we could get water on it.

It was now evident that all hopes of saving the miner had to be abandoned, and we turned our attention to smothering the fire. We entered through a door into the return airway, but were greeted by such a blast of heat, smoke, sparks and falling roof that we were compelled to retreat immediately. Crossing back to the intake airway, the door had scarcely been closed when an explosion occurred, the flame sweeping out over us as we dropped to the bottom. Fortunately, the flame was only of short duration, but it left the most surprised, frightened, disgusted and discouraged set of mine officials struggling in the mud, water and inky darkness that could be imagined. This explosion was caused, I think, by the accumulation of carbon monoxide near the fire after the door was opened.

We now closed off the intake temporarily with boards, opened our way into the return again by using canvas, and finally closed off both with brick stoppings. I think about 12 dams were then built, holes drilled from the surface, and the section flooded, which took several weeks.

I wish to add that the men working at this fire were all experienced and well posted mining men. One was a company inspector, another a mine foreman who a few years later was appointed state mine inspector, and we all should have known better than to have cut off the ventilation over the fire and then restore it again, as we did. It is a striking example of the difference between planning under assumed conditions, and actually working under any old conditions on a moment's notice, especially when human life is at stake.

J. T. Colburn.

Uniontown, Penn.

Letter No. 27—I was much interested and pleased to see your issue of Feb. 3. The discussion on mine fires will certainly tend to clear up this much-talked-of question.

As far as I am able to judge, *Letter No.* 2, by Edw. H. Coxe, gives the solution to the question and the reason why in a nutshell. My own conclusions are: Place your men where they will not inhale the fumes. There is absolutely no more danger in sealing off a fire from the intake side than in any other work of that nature, as, for instance, in timbering-off and stopping-off a squeeze.

No official has any moral, pecuniary, or physical right to place his men in more than necessary danger to produce the desired results of safety to life and protection to property. For half a century, I have been working in and about the mines—two-thirds of the time underground—and have worked at many fires. I always have, and in the future will continue to place my men first on the intake side. You can probably hurry matters by having the men build both stoppings simultaneously, but the workers on the return will suffer more or less from the effects of the fire, and the result will be bulging eyeballs, headache and nausea.

I was much interested in letter No. 5, which advocates fighting the fire from the intake side, but when it comes to sealing off the trouble, this gentleman recommends building the first stopping on the return. In this connection, let me say, the conditions are similar. Suppose a large amount of CH_4 is being generated in both headings. This gas drifting from the intake to the return over the fire will surely ignite and light the gas in the return. And furthermore, my experience has been it will keep burning until suffocated, or extinguished; or until the pressure of the blower is reduced to an intermittent one.

Two Fires in One Heading

I have had two fires in one heading, each one larger than a gas-grate, burn for 13 days and nights, until we forced up a crosscut on the other side. This gave us no fear, because the products of combustion were carried direct to the return and there was nothing to explode.

It is quite different with the argument put forth in letter No. 5. I can easily understand how the gas from the return could diffuse through the products of combustion, harmless enough until they reached the still smoldering fire; then there would be a flash, slight perhaps, but sufficient to knock down your men.

In sealing off a fire, we have three most important things to accomplish: 1. Suffocate the flaming gas by its product CO_2. 2. Smother the coal fire by the inert pure CH_4, and free N and the CO_2 products. 3. Make your stopping stronger than the pressure of the blower and the expansion of the heated gases.

I also notice that the "intake" advocates give reasons, while those who advise closing the return first are supported only by theory. Let me ask all coal men to read, mark and learn, and perhaps we may be able to save a life or two, even tomorrow. I am sure the valuable discussion that has occurred will cause hundreds of us to consider the methods outlined and be wholly prepared in case of emergency.

Joseph Virgin,
Supt. of Mines.

Plymouth, W. Va.

Mr. Norris Answers Mr. Garcia

Mr. Garcia has evidently misunderstood my letter, in regard to closing off a mine fire, in making his criticism.

In suggesting a procedure in the case of the evolution of large volumes of gas at the seat of the fire, I had in mind conditions not uncommon in the anthracite region when the full air current may be needed up to the moment of closing, to dilute the firedamp, and not merely the possible products of combustion.

I have too much respect for the character of your readers to assume that any one of them would be senseless enough to reverse an air current with the returns in irrespirable condition; the original assumption of a fire beyond control presupposes ample time in fighting it to obtain a knowledge of the state of the workings. Under proper conditions the air current *can and should be reversed.*

After all, the way to fight a fire is to get at it promptly and let the method of procedure be governed by the conditions.

R. V. Norris,
Consulting Engineer.

Wilkes-Barre, Penn.

[*We expect to close the discussion on mine fires next week, when W. D. Owens, superintendent for the Lehigh Valley Coal Co.; J. C. McDermott, chief mine inspector for Montana, and others will express their opinions.*—Editor.]

The Davy Lamp in Testing

I notice in Coal Age, Dec. 16, 1911, p. 322, in answer to the question, "What is meant by the flame test?" you state the Davy lamp is a favorite lamp for testing for gas. In my travels I have found many who say the Davy lamp is unsafe, owing to its liability to flame, and in some localities it is prohibited by law. Why is the Davy lamp so often preferred, when the Wolf lamp will show ¼% of gas, and is called safe in all countries.

J. H. Needhammer, Supt.

Sullivan, Ind.

The Davy lamp, owing to its simplicity of construction and sensitiveness to gas, has always been a favorite lamp among firebosses and still holds its prestige. It is not a safe lamp to place in the hands of an ordinary miner, and is not adapted to general work at the face. The use of the unbonneted Davy is prohibited by the old mining law of Great Britain. The new law, which will probably go into effect not later than Jan. 1, 1913, does not mention the Davy or any other lamp specifically, but requires that no lamps shall be used in any mine other than those provided by the owner of the mine and approved by the Secretary of State.

In the United States, as far as our knowledge goes, the only prohibition by law of the Davy lamp or any other lamp, occurred in the old bituminous-mine law of Pennsylvania, which forbade the use of the Davy and the unbonneted Clanny lamps for general work in bituminous mines, but permitted their use by mine officials, examining the mine for gas.

Because of the free circulation of air in the lamp, the inside atmosphere of the Davy most closely approaches the same gaseous condition as that of the air surrounding the lamp. The flame cap, however, as is well known, is not visible in this lamp until the gas reaches 2 per cent., and many firebosses fail to detect a cap in less than 3 per cent. of gas. For this reason an indicator should be used in the Davy, capable of showing small percentages of gas.

The Wolf lamp burns naphtha, a highly volatile oil that reveals a flame cap at about ½ per cent. of gas. The indication of ¼ per cent. of gas, as stated by our correspondent, is extremely uncertain and not apparent to most observers. The lamp is not a good testing lamp for several reasons; namely, the lamp is bonneted, which fact, together with the vaporous oil burned, modifies, at times, the atmosphere in the combustion chamber, so that it does not truly represent the gaseous condition of the outside air. The lamp heats readily in gas, the oil volatilizes more quickly and the lamp gives higher indications than it should, after being exposed to gas a short time. The lamp flame is easily extinguished, and when relighted, after a short period of extinction, the lamp may flash (pass flame).

Opinions vary in regard to the use of naphtha or other highly volatile oil in mine lamps. The slightly improved illumination scarcely compensates for the increased danger arising from the explosive nature of the oil burned. The same difference of opinion exists in regard to the use of the various carbide or acetylene lamps. At the present time, electric lamps are receiving much attention. The chief objection to electric lamps, however, is their inability to reveal the gaseous condition of the mine air.

Mine Telephones as Life Savers

Relative to the explosion at our mine No. 7 at Radley, Kan., on Jan. 3, in which it was reported that the two shotfirers, J. W. Keeran and W. M. Martin, were saved from death by means of the mine telephone, I wish to state, in my opinion, this is correct. We have a mine telephone law in this state which went into effect last fall, and all of our mines are equipped with telephones.

In regard to this particular accident would say that the mine telephone undoubtedly resulted in our being able ot save the lives of these two shotfirers. In all of our mines we have a system of requiring the shotfirers to report by means of the mine telephone to the night engineer, the progress of their work as they go through the mine lighting the shots; by this means we know at all times just about where the shotfirers are The night engineer also becomes thoroughly acquainted with just the manner in which the shotfirers fire the mine, and knows just when, within a few minutes, a certain shotfirer should report from a certain station. In the event that he fails to report the engineer suspicions something wrong, and when this runs over ten or fifteen minutes past the usual time he summons help.

At the time of the explosion in our mine No. 7 we had, in addition to the regular mine telephone, installed a telephone in a refuge hole for the shotfirers. This refuge hole was provided with a door, the idea being for the shotfirers to light a certain entry and get in this refuge hole while the shots were going. The particular entry for which this refuge hole was installed had been giving us considerable trouble in the way of windy shots, and we, therefore, took this additional precaution.

When the explosion came one of the shotfirers was in the act of ringing the engineer to tell him that they had lighted the shots in this entry. The force of the explosion was so strong that it blew in the back end of the refuge hole, and the shotfirer did not even get to talk, but was immediately overcome by the afterdamp. His partner, who was with him, was likewise overcome. The night engineer, knowing that this was the station from which they should next report, immediately tried to call them, but was unable to get any response and started the distress whistle. In fifteen minutes after the explosion had occurred a rescue party was in this refuge hole and had the two shotfirers out working upon them and succeeded in resuscitating them. A little later it would undoubtedly have been impossible to revive them.

I might say that our mine telephones are so installed that they are practically explosion proof, the wires being laid in pipe along the entry. We have had three quite severe explosions in this particular mine this winter and none of the telephones was damaged in the least.

C. W. Waterman,
Pittsburg, Kan. Mine Supt.

Question on Shot Firing

Discuss briefly the question of the advantages arising from, and the risks incident to, the very common practice of firing two or more shots at the same time, in an entry or room.

Seanor, Penn. J. N.

[At the earnest request of a correspondent we submit the above question for discussion, and hope the readers of Coal Age will respond freely and give the results of their experience or state their own views.—Editor.]

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Cross-Bar Timbering in Mines

We have had some considerable trouble in our main-haulage-road timbering. The cross-bars, which are a good quality of straight-grained, white oak, seem to have a tendency to split at the notch, as I have shown in the rough sketch (Fig. 1) I am sending you. Can you or any of the readers of COAL AGE tell me the trouble and suggest a remedy? We have a rather weak, shale roof and a soft fireclay bottom. The coal (bituminous) is 5 ft. 4 in. high and overlaid with a 10-in. drawslate that falls a few yards behind the face and before the timber frames are set up.

The air cuts the roof at each rib badly, and then the trouble with splitting of cross-bars begins. Please explain why the roof cuts at the ribs where the velocity of the air is less than at the center.

Pittsburg, Kan. ANXIOUS FOREMAN.

From the excellent sketch (Fig. 1) you have sent us, there appear to be at least two main reasons for the splitting of the cross-bars at the notches. (1) The cross-bar appears to be tightly wedged its entire length. (2) The legs are not properly jointed to the cross-bar. These causes are probably greatly augmented in their effect by the cutting of the roof at each rib.

When roof "cuts" it is almost invariably along the ribs of openings. It occurs more generally in entries and passages where a good current of air is traveling and less frequently in rooms. The trouble is commonly attributed to the air current, which is said to "cut the roof"; but this does not express the reason for the cutting.

Cutting occurs chiefly in mining coal under a roof that disintegrates readily under pressure; or in other words, crumbles under excessive roof pressure. This crumbling is greatly augmented by the action of the air current on the moisture escaping from the stone, slate, or shale. The action is greatest along each rib, because that is where the crunching of the roof is greatest. The crumbling of the strata at the rib, however slight, facilitates the escape of moisture, which in turn assists the disintegration. The cutting is thus largely due to excessive roof pressure, for the particular roof in question. Its remedy must be sought in: (1) enlarging the entry pillars and stumps; (2) reducing the length of rooms and carrying a smaller area standing on props; in other words, shorten the time rooms must be kept open, draw back pillars and let roof fall as quickly as possible in the rooms; (3) a proper system of timbering.

The cutting of the roof at the rib lines throws an extra burden on the cross-bar, and the manner of wedging the timber its entire length, as shown in Fig. 1,

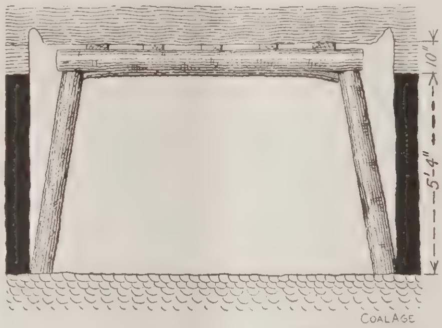


FIG. 1. WRONG METHOD OF WEDGING AND NOTCHING A CROSS-BAR, CAUSING BAR TO SPLIT

makes the bar take the whole weight over the span and naturally bends the bar and starts the splitting at the notches.

WEDGING A TIMBER FRAME

Observe in Fig. 2 there are no wedges driven over the central portion of the span; but two good flat wedges are

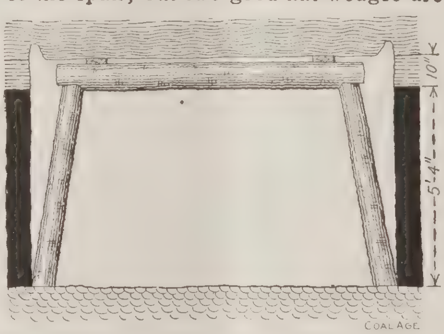

FIG. 2. PROPER METHOD OF WEDGING AND NOTCHING A CROSS-BAR

driven, one on each side, just in from over the top of the leg. The effect of this is to arch the weight over the span, throwing it on the legs at each side, and leaving the cross-bar free to resist the thrust of the legs inward with its entire strength.

NOTCHING A CROSS-BAR

When setting up a timber frame first take down any loose rock or slate that should not remain; clear away rubbish and cut a solid foothold on the floor against each rib where the timbers must stand. Now, measure the spread of the legs at the floor, inside of timbers, and the vertical height from the floor to the under side of the collar, allowing for the thickness of the collar and wedges. From the inside spread of the legs at the floor subtract from 3 to 4 inches, for each foot of height; and the remainder will be the distance between notches. The collar or cross-bar must be sufficiently longer to allow a full bearing for the head of each leg.

It is important to cut the notches on an angle of 45 deg. and make a smooth flat bearing for the head of each leg. The top of each leg must then be sawed to fit this bearing as shown in Fig. 2. By this arrangement each leg will lean toward the center of the entry from 1½ to 2 inches for each foot of headroom under the collar.

Gases Distilled from Coal Dust

Assuming a coal dust having the following proximate analysis:

Moisture	1%
Volatile matter	28%
Fixed carbon	63%
Ash	8%
	100%

and supposing the temperature of the dust to be gradually raised without bringing it into contact with flame; in what order will the various gases be distilled and at what approximate temperatures?

Lethbridge, Canada. ENGINEER.

Coal exposed to a free atmosphere gives up much of its moisture. It also loses some of its occluded gases if such are present. This emission of moisture and gas takes place at all temperatures until saturation of the surrounding atmosphere occurs. As the temperature is raised the emission becomes more rapid.

It cannot be definitely stated at what temperature oxidation begins, since coal absorbs oxygen from the air and it is possible the absorbed oxygen enters into combination with some of the elements of the coal. But, sensible combustion of carbon with production of carbon dioxide, or carbon monoxide, or both, according to conditions, occurs at about 300° to 350° F. The temperature at which spontaneous ignition of fine coal dust will take place must, evidently, depend on the nature of the coal and the fineness of the dust. This temperature is given as 284° F. (Bedson); 356° F. (Fayal), Mine gases and Exlosions, page 155.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions for Beginners

BELT-DRIVEN VS. DIRECT-CONNECTED FAN

Ques.—What are the advantages and disadvantages of a belt-driven fan?

Ans.—The belt makes it possible to attain any desired speed of fan for the same speed of engine by changing the pulley on the fan shaft or on the engine. It is also plain that the belt-driven fan runs more smoothly and is not as hard on the engine as a direct-connected fan. When the fan is belt driven, it is possible to employ a smaller size of engine run at a higher speed for any given power and speed of fan. The chief advantages of a direct-connected fan are: The fan is under better control; and there is no loss of power by the slipping of the belt.

SIZE OF DRILL—SOLID SHOOTING

Ques.—What size of drill (diameter) would you recommend to be used when shooting off the solid?

Ans.—In shooting off the solid, it is particularly desirable to avoid the use of too large a drill. The diameter of the bit should not exceed 2 or 2½ in., depending on the hardness of the coal. It must be remembered that the diameter of the hole is always greater than the diameter of the cutting bit. A drill hole of too large a diameter causes too great a localization of the charge and produces what is known in mining as a tight shot, which may blow the tamping instead of breaking down the coal.

MINE-HAULAGE SYSTEMS

Ques.—What system of haulage would you consider best adapted for mines, under the following respective conditions: (a) When the haulage roads have an uneven grade? (b) When there is a grade of 5% against the loads? (c) When the haulage roads are fairly level?

Ans.—(a) When the grade of the haulway is uneven or variable, the tail-rope system is generally preferred as being more readily controlled.

(b) For a grade of 5% against the loads, a combined gravity and engine-plane system should be employed, in which the weight of the descending empty cars would partly balance the weight of the ascending loads; and to that extent relieve the load on the engine.

(c) When the haulage road is practically level, the endless-rope system gives the best results.

MINE GASES

Ques.—In dealing with carbureted hydrogen, is any other danger to be guarded against besides that of explosion?

Ans.—The possible ignition of the firedamp that is formed when this gas is mixed with air in certain proportions is the chief danger to be feared in dealing with marsh gas, CH_4 (carbureted hydrogen). Pure marsh gas undiluted with air would, of course, suffocate, as it contains no available oxygen; but this danger is not possible in any ventilated workings. The gas diluted with air produces no ill effect when breathed, except it may be a slight dizziness if much gas is present.

COMPOSITION OF ATMOSPHERE

Ques.—Of what is atmospheric air composed?

Ans.—The composition of pure air, by volume, is: nitrogen, 79.1%; oxygen, 20.9%; and small amounts of carbon dioxide, moisture and other rare elements, which it is not important to mention.

EFFECT OF TEMPERATURE IN MINE

Ques.—If the temperature of a mine passing a large volume of air is 50° F., while that of the outside atmosphere is 80° F.; (a) what effect will this difference of temperature have on the circulation of the mine? (b) In what other way will it affect the condition of the mine or airways?

Ans.—(a) In a slope or shaft mine, or in a drift mine ventilated through a single shaft sunk back on the hill, this difference between the inside and outside temperatures will create an air column that will either assist or oppose the circulation. In the one case, the installed or artificial circulation will be supplemented by a certain natural current, increasing the circulation in the mine; in the other case, the natural agency will oppose the artificial means and the mine circulation will be reduced thereby.

Wherever practicable, the artificial circulation should be arranged to conform to the natural circulation during the winter season, when the inside temperature is above that of the outside air, as the mine activities are greater then, and the mine has greater need of an ample supply of air.

(b) The air entering the mine at 80° F. may carry sufficient moisture to exceed its capacity when cooled to 50° F. In that case, there will be, at times, a considerable amount of moisture deposited on the walls, roof and timbers in the airways; and, at other times, when the outside air is drier and carries less moisture, the air current in passing through the mine will take up moisture. This alternate wetting and drying of the mine timbers rots the wood and shortens the life of the mine timber. The same wetting and drying is hard on some mine roofs, causing the roof to crumble and crack.

EFFECT OF PRESSURE ON FIREDAMP

Ques.—Is firedamp compressible; and how is it affected by a decrease of atmospheric pressure?

Ans.—Firedamp being a gaseous mixture is compressible, as are all gases and air. Gases are compressed by any increase of pressure, and expand when the pressure is decreased, the compression or expansion being in the inverse ratio of the absolute pressure. For example, 29,000 cu.ft. of firedamp in an abandoned room in a mine, is expanded to 30,000 cu.ft. when the barometer drops from 30 in. to 29 in. These ratios are expressed as follows:

$$\frac{2d\ volume}{1st\ volume} = \frac{1st\ pressure}{2d\ pressure}$$

$$\frac{30{,}000\ cu.ft.}{29{,}000\ cu.ft.} = \frac{30\ in.}{29\ in.}$$

In this case, the difference 30,000 — 29,000 = 1000 cu.ft. of firedamp would be forced out of the room into the entry. If this fall of barometer took place in, say 10 hours, every 29,000 cu.ft. of space in abandoned rooms in the mine would furnish 100 cu.ft. of air or gas per hour during the fall. In gaseous mines this often causes serious trouble by rendering the mine air highly explosive when least expected by men underground.

STOPPING OFF AIRWAY, EFFECT ON FAN

Ques.—If an air-tight stopping be erected in the main-return airway 100 ft. from the fan, what effect will be produced on the fan?

Ans.—The erection of the stopping in the main return will stop the circulation of air, and no air will pass through the mine or the fan. Now, assuming the power applied to the fan shaft remains unchanged, the fan will run faster after the stopping is built than before; because, there being no air passing, no work is lost or absorbed in the fan and all the power is now available for turning the fan. Hence, for the same power, the speed of the fan is increased by stopping off the air course.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

The Other Half

By Charles L. Fay*

In these days of social unrest, there are many organizations and committees, which have come into existence aiming to be mediums though which the prime-moving spirits may have an opportunity to express in deeds their overwhelming conviction of the need that something should be done to contribute toward a clearer understanding of present social conditions, and to aid in the betterment of society.

Usually a fitting background is arranged by securing the coöperation of men and women of superior character and of a national repute in such matters as pertain to civic progress, philanthropy and humanitarianism. Too often, perhaps, both the men and women, whose wealth or position, integrity or state or national standing make them leaders, lend their names and nominal interest to an enterprise while the policy and the labor of development are left to the discretion of the zealous promoters. This occurs, possibly, because the *objective* of the plan is noble and the *principle,* in general, well established. It is easy to enlist approval from those who are already too active in other lines to contribute any personal assistance or direction in the promotion of the enterprise, but it is not easy to secure their effective support.

Having proceeded thus far, under the influence of an earnest and honest enthusiasm, and under the spell of genuine oratory and devotion, the development of the organization is delegated to *specialists* who, of necessity, have created the movement, or are related to it in a professional way.

Surveying a La Mode

Thus we have committees, foundations and societies with general offices, branch offices, national and state divisions, equipped with publishing houses, official organs, publicity bureaus and corps of statisticians, writers and investigators. Conventions and conferences are numerous. Surely in this day "one-half the world is seeking to find how the other half lives."

Of the making of "reports" there is no end. Many thousands of dollars annually lubricate the wheels of that machinery which ceaselessly grinds out data wherewith to fill reports that other data may be secured, from which other reports may be made and further investigation aided. Additional conferences are held, happily around the banquet board, to call yet more conventions that other lengthy reports may be fruitful in yet more brilliant oratory, influencing still further investigation whereby remedy may be discovered for social ills, and *the other fellow* made unselfish.

The Surveyed

Surely one-half of the world is striving to show the *other half* how to live and pursue happiness. The *other half* ought, at least, to be very grateful for the self-sacrifice and unselfish devotion of the mighty host which labors so diligently over mahogany desk, on pullman car and around the banquet board for so great a purpose!

Who compose the *"other half"*? The captains of industry, the employers and the industrial workers, the courts, the law makers and the guardians of the peace, the churches and the public schools. Of course, the courts, the law makers, the guardians of the peace, the churches and the public schools are only in a degree part of that *"other half."* That is, they belong to it only in their relations with the "hewers of wood and the drawers of water"—the industrial workers.

What an impressive spectacle it would make if the mighty army of social betterment specialists with their equipment could form in one general convocation at a point where the *"other half,"* from ocean to ocean, could see the men and women—in their world but not of their world—studying, working and investigating unselfishly for their benefit. Surely there should soon be no "other half"—selfishness would be swallowed up in unselfishness and segregation would be displaced by coöperation.

Let us look more directly to the operators or specialists of this product of social unrest and to the methods they employ, in order to discern if we may, some obstacles to the progress of truth and civilization.

Many Remedies

All realize that the social unrest is the evidence of wrong social conditions, but like the experts of various schools of medicine, each "school" for social betterment seems to diagnose the case differently and then prescribes its own remedies, while the "other half" cries out "Oh, wretched man that I am!" and Job, as he listened to the advice of his three officious, self-satisfied friends, is better understood.

One specialist says to the "other half," you must combine and *fight* for your rights. Another says, you must develop "class consciousness"; another teaches "class hatred"; another directs the "other half" to recreation, amusement and contentment with its lot and place in society, and still others teach paternalism and the high ideals of coöperation. There is anarchy, political socialism, trade unionism and coöperation battling against corporate and individual (assumed or established) prerogatives and the spirit of selfishness and segregation.

All the while "investigation" is followed by "investigation" while agitation is epidemic. The "other half" will soon be resigned to the operating table. All this is but an illustration of the difficulties under which truth has to progress, through the débris of human *miscomprehension.*

I would not minimize the wrong conditions that exist nor undervalue the great aid that various social-welfare organizations, committees and foundations are to the progress of society. Society is debtor to the self-sacrificing and intelligent efforts of many welfare specialists; but it *will not* be amiss to call attention to some types of superficial investigation that contribute to the development of wrong and biased public opinion which, consequently, is based upon wrong conclusions and not upon facts.

The specialists specialize *apart* by "schools" and humanity pays the price of its own *temperamental divisions.* Let us consider, then, the individual investigation—the *dynamic* of every organization, society and committee.

Steiner's Inductive Method

Would that we had more Dr. Steiners—men who contrive to *live in* the *stratum* of the society they would investigate and then labor to aid in its uplift! Dr. Edward A. Steiner studied the immigrant races in North America as *an immigrant—lived the life—was the life* of the society he came to benefit—when he *investigates* he does it with a comprehension of the lives of the men he would *uplift* and a consciousness of the values of the social status to which he would lift them.

(To be continued)

*Mining Secretary, Penn. State Y. M. C. A., Wilkes-Barre, Penn.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Senate committee on inter-oceanic canals has just published the proceedings of its investigation into the use and distribution of coal on the Isthmus of Panama, made during the recent visit of the committee to the Canal Zone. It appears that considerable attention was devoted to the coal question and particularly to the position of the Panama Railroad Co. with regard to it. No one is allowed to sell coal in the Canal Zone except the railroad, although there is no regulation or law that prohibits anyone from so doing. While there are a few small dealers in charcoal, there is no other dealer in bituminous coal either small or large.

The price of coal is fixed by the president of the railroad who determines the rate at which it shall be sold commercially to ships. A profit of about 33⅓ per cent. is made when the coal is sold to private individuals. The Pacific Mail Steamship Co. and the Bates & Chesebrough line are furnished coal at the same price at which the Canal Commission buys it and the profit on this coal is a small one, amounting to not more than 5c. or 10c. per ton.

Recommendation by Col. Goethals

Colonel Goethals urges that the government should arrange to furnish coal to private shipping and estimates that for the use of the navy alone, a storage capacity amounting to 200,000 tons, with a maximum increase of 50 per cent. should be provided on the Atlantic side and that provisions for storing 50,000 tons of coal with a possible increase of 100 per cent., should likewise be made on the Pacific side of the canal. He thinks that the government would be able to sell coal to private vessels and regularly replenish its supply so as to keep on hand a constant residuum, representing the amount needed by the navy on the basis of the figures indicated.

Considerable attention has also been given to the question of supplyng petroleum for fuel use by vessels and to the best methods of storing and handling this material.

The data filed with the House Committee on Interstate Commerce relative to the rates for coal charged by the Panama R.R. Co. are considered to show that these charges are unreasonably high in so far as they apply to private commercial buyers on whose coal the Senate testimony showed that a profit of about one-third was being made. The present indications are that new legislation relating to the Panama Canal will call for a governmental system of selling coal that will be somewhat like the plan that has been outlined by Colonel Goethals.

Public Coal Land in Alabama

The Senate, on Feb. 5, passed a bill that extends the operation of the act of June 10, 1910, to cover coal lands in Alabama. The bill, as now before the House, is as follows: "That all the public lands containing coal deposits in the state of Alabama which are now being withheld from homestead entry under the provisions of the act entitled 'An act to exclude the public lands in Alabama from the operations of the laws relating to mineral lands,' approved Mar. 3, 1883, may be entered under the homestead laws of the United States subject to the provisions, terms, conditions and limitations prescribed in the act approved June 10, 1910."

Joint Rates and Rebates

The Interstate Commerce Commission has rendered a decision in the matter of divisions of joint rates for transportation of coal to points in North Carolina from points in other states, in which it finds that:

"1. The doctrine that this Commission has no concern with the divisions of rates which carriers make by agreement with each other has decided limitations, and if a railroad is a shipper, or is so linked up with a shipper that a division of a rate means a rebate or a discrimination in favor of or an advantage to a shipper, this Commission may properly look into the nature of the service which the carrier gives and the division which it receives.

"2. Where the industry-owned carrier, by virtue of a trackage agreement with a trunk-line carrier, conducts its operations in part over the trunk line's rails, that fact becomes an additional reason why this Commission may take cognizance of the divisions of joint rates to which the industry-owned carrier is a party."

Mine Rescuers Bill Passed

A House bill extending to the employees of the Bureau of Mines the right to receive compensation from the government for injuries received while on duty was passed, Feb. 5, by the Senate. The bill now goes to the President.

California

Amador—Sixty-five miners were imprisoned, Feb. 7, by a cave-in at the Bunker Hill mine, near Sutters Creek. The men were entombed at the 200-ft. level of the shaft. A rescue party was able to get into communication with them by the following morning. None of the men were injured, and their chief danger lay in the possibility of another cave-in. The Bunker Hill mine is one of the oldest and most famous mines in California. The accident was due to the collapse of timbers that were rotted with age.

Colorado

Denver—The state land board proposes to regulate the price of coal mined from state land leased to operators. The Consumers' Coal Co. has applied to the board for a lease on school lands at a point 20 miles north of Denver, and was informed that the company must agree to sell coal in Denver at a price not to exceed $4 per ton. The company was willing to agree to a proposition that it should not seek more than 50c. a ton profit by the sale of the coal, but the board wanted it understood in the agreement that a charge of not more than $4 per ton, delivered, should be made in Denver. The matter was taken under consideration by the company.

Lack of activity on the part of state officials to afford protection to the nonunion men working in the northern coal fields and the failure of the state administration to compel the sheriff of Boulder County to maintain order there have forced the operators to seek Federal protection. Recently the Rocky Mountain Fuel Co. filed an application for an injunction in the United States district court to prevent members of the United Mine Workers of America from interfering with employees of the company and the company itself at its mines in Louisville, Marshall, Lafayette, Superior and Erie. Final hearing in the case will be held Feb. 19. Arguments will then be presented as to whether a permanent injunction shall issue. Action upon a temporary injunction was practically waived by the company.

Illinois

Belleville—Freeburg, about eight miles southeast of here, has almost been depopulated recently on account of a practically complete suspension of operations in the coal mines there. The men have

gone to Belleville, French Village, O'Fallon, Collinsville and other coal-mining centers for employment. The suspension at the mines, it is said, is due to the inability of the operators to obtain railroad cars for the shipment of their output. Operators say the Illinois Central, whose freight service is said to be crippled as a result of the strike of the shopmen, has been furnishing only about one car to each of the four mines at Freeburg once a week.

Paris—It was announced recently that a seam of coal has been found on the Morton farm, near Nevins, at a depth of 610 ft. The vein is 6 ft. thick, with a sandstone roof 14 ft. in thickness. The same vein has been struck, in boring for oil, in the same township at a depth of 784 ft. Two other seams of minor importance were struck, one at 370 ft. and one at 404 ft. It is reported that representatives of the United States Steel Corporation are securing leases in the vicinity and will investigate the field.

Danville—On Feb. 9, the hoisting wheel at the Fairmount Coal Co.'s mine at Bennett Station broke and a cage dropped a short distance and stuck in the shaft. No one was injured, but there was no way left for getting the miners out because the air shaft was blocked with ice. After being imprisoned for 15 hours, the 50 miners were released by a rescue party that succeeded in chopping the ice from the air shaft.

Springfield—About 800 miners recently went on strike at Witt, near here, and 200 more, at Kortkamp, were also induced to strike. The men of Burnwell No. 2 mine, at Witt, demanded the discharge of a mule boss, against whom they had a grievance and the company refusing to accede, a strike was declared. Efforts to effect a settlement have been unavailing.

Indiana

Gary—Eight of the ten blocks of by-product coke ovens being built at the U. S. Steel company's plant, have been completed. This means that about 450 ovens are in operation. The completed plant will consist of 560 ovens, with a daily capacity of 7000 tons.

Indianapolis—Representatives of the Western Federation of Miners and of the United Mine Workers of America held a meeting in Indianapolis, Feb. 7, and effected a tentative organization of a miner's department of the American Federation of Labor. Charles H. Moyer, of Denver, Colo., president of the Western Federation, was elected head of the new department.

The announcement that a railroad will be built from Gary to Vincennes makes the outlook bright for the development of the coal fields in Knox and Gibson Counties, Indiana. Discoveries, within the last few months, of a vein of coal of excellent quality, together with the steady operation of existing mines is said to have induced the Steel Corporation to extend its railroad connections. The Indian Creek Mining Co., which recently opened one of the best equipped mines in the state, is now employing several hundred men. Two additional shafts are to be sunk in the spring. New mines are also being opened in Gibson County near Bicknell.

Kentucky

Barbourville—The Clover Fork Coal Co. has the grading done for its incline at its new mine on Clover Fork above the town of Harlan. The spur line of railroad being constructed up Clover Fork, to the property of the Clover Fork Coal Co. and the Harlan Coal Co. is completed for a distance of between one and two miles and work is going forward as rapidly as the weather will permit.

Lexington—A bill has been introduced in the Kentucky legislature that provides for a tax assessment of one cent on every ton of coal mined.

The Commercial Club of Lebanon, Ky., has filed a protest with the Interstate Commerce Commission complaining that the rates on coal over the Louisville & Nashville R.R. from Big Stone Gap and Norton, Va., and from the fields in Tennessee are unjust and discriminatory.

Louisville—Benham, another of the magic cities of the eastern Kentucky coal fields, that has sprung up as a result of the rapid local development, has now a population of about 3500. Benham is on the newly completed line of the Wasioto & Black Mountain R.R. and was started by the Wisconsin Steel Co. The Wasioto & Black Mountain is being pushed into Harlan County and the population of Harlan is expected to double in the next 12 months. Dozens of small towns are springing up in that section. Poor Fork is developing into a mountain metropolis. In time, it is said, the Wasioto & Black Mountain will be extended to the head waters of the Cumberland, where rich coal fields abound in the upper Black Mountain section.

Following the announcement from the coal mines in Kentucky that they were unable to secure cars from the Illinois Central R.R. for commercial shipments of coal, railroad officials claim that they are now furnishing the mines with cars and that coal is being received for revenue shipments.

Michigan

Corunna—The Kerby Coal Mining Co., with property consisting of $35,000 in coal leases, and owned principally by Tod Tincaid, of Detroit, has been dissolved on application of S. Q. Pulver, a stockholder. The company never engaged in mining.

Detroit—This city's threatened coal famine assumed a more serious aspect, Feb. 1, when announcement came from the Detroit City Gas Co. that the supply of coke was at the point of exhaustion. At the same time it was learned that the Solvay Process Co. is away behind in its supply of this commodity. Serious shortages of coal supply are reported from throughout the state and the situation at many points threatens to become critical in the event of continued cold weather and lack of relief in the matter of transportation.

Missouri

St. Louis—Traffic representatives of the railroads interested in the proposed abolition of the arbitrary on coal within a 100-mile radius of St. Louis met recently in the offices of General Manager McKeen, of the Vandalia. This was the second conference held in an effort to arrive at an agreement by which the roads could meet the demands of the Business Men's League Traffic Committee. According to Mr. McKeen, nothing definite has been decided. He could not predict, he said, how soon an agreement among the railroads would be reached.

North Carolina

Charlotte—William Guthrie, of Durham, acting for a Philadelphia syndicate, has completed a deal for the purchase of the Cumnock coal-mine property in Chatham County, embracing 2700 acres of land and the only coal mine in North Carolina. The purchase price is given as $60,000. The mines, where a low-grade bituminous coal is found, will probably be developed. They have not been worked for several years, the low-grade coal not competing for most purposes with the West Virginia and Tennessee product.

Ohio

Canal Dover—Surveyors employed by the Pennsylvania R.R. Co. are at work on what is believed to be a proposed extension of the Cleveland & Marietta division of the system, to connect with the Cleveland, Akron & Columbus division at Orrville, giving the line a river to lake route. The line would be about 30 miles long, and would lessen the haul to Cleveland from the coal fields along the Cleveland & Marietta branch by about 25 miles.

East Liverpool—The West Point Coal Co., which operates several mines on the Youngstown & Ohio River R.R., six miles north of this place, plans to establish large coal-storage yards here to develop the trade among nearly 50 potteries in the vicinity. The West Point Coal Co. was organized several years ago by J. L. Francis, of Chicago, and it was only after his preliminary surveying

of nearly 20,000 acres of land in the central part of Columbiana County that it was known that large deposits of coal existed there. As soon as the Youngstown & Ohio R.R. Co. can establish a switching arrangement with the Cleveland & Pittsburg railroad, the West Point Coal Co. plans to ship the greater part of its product south by the Ohio River.

Oklahoma

Coalgate—The shaft of the new mine being opened here by the coal department of the Missouri, Kansas & Texas Ry. has been completed and one of the best veins of coal in the Southwest developed. It is expected that the new mine will be in operation within a few weeks and employment given to 300 miners. The completion of the shaft was celebrated by firing a number of shots of dynamite.

Pennsylvania

Bituminous

Irwin—The coal trade is now at about capacity production in the Irwin district. The Yukon mine, shut down to make repairs, started, Feb. 6, and 600 men returned to work. The Pleasant Valley mine, north of town, is now running, after an idleness of nearly two years. Edna No. 1 and No. 2 mines of the United Coal Co. have twice as many hands employed now as on Jan. 1. Operators declare the Pennsylvania railroad is doing wonders in moving coal to the markets during the extremely cold weather.

Scottdale—The old Dexter coke plant, near Scottdale, together with the underlying coal, was recently transferred from the Stauffer estate to Connellsville interests for the sum of $30,000. The deal includes the coal under several tracts in Upper Tyrone township, the complete equipment of 40 ovens, all in good repair, and the necessary mining rights and trackage. The new owners are said to be making preparations to at once get the plant ready for a steady run. It has been idle since the slump in the fall of 1907.

Ebensburg—Local owners of coal land have been interested lately in the activities of two men who have been endeavoring to secure options on a 5000-acre tract of coal lying immediately northwest of Ebensburg. It is not known what interests they represent, but the name of J. Blair Kennerly, of Philadelphia, has been mentioned in this connection. Mr. Kennerly owns mines in Cambria, Clearfield, Blair and Indiana Counties.

Pittsburg—The brief of former Attorney-General Wade H. Ellis, as chief counsel for the Pittsburg district coal operators, against the freight rates to the lake ports of the coal-carrying railroads, was filed Feb. 6, with the Interstate Commerce Commission in Washington. The arguments will be heard on Feb. 19, and a heated discussion is forecasted by the claims made in the brief.

Fire, Feb. 9, partly destroyed the tipple at the Grant mine of the Pittsburg Coal Co., at the west end of Carnegie. The damage is estimated at $500. The fire caused great inconvenience to the Pittsburg, Cincinnati, Chicago & St. Louis Ry. Co., as it ordinarily uses the tipple for coaling engines several hundred times a day.

Anthracite

Scranton—The big modern breaker and the steam plant of the Connell Anthracite Mining Co., at Bernice, were destroyed by fire, Feb. 2, entailing a loss of $150,000, fully covered by insurance. The breaker being some distance from the head of the shaft, the lives of the men inside were not endangered. Live coals falling on oil soaked woodwork or an overheated boiler is believed to have caused the fire. It started in the boiler room and quickly spread to the breaker proper and then to the office building adjoining. The colliery buildings were all comparatively new, having been erected since the opening of the Bernice coal field not many years ago. The fire throws over 500 men and boys out of employment.

Wilkes-Barre—Work is well underway upon the new Stackhouse breaker that is being erected in Salem township near the Shickshinny line about 11 miles above Berwick. The breaker will cost approximately $80,000 and will be one of the most modern in Luzerne County in construction and equipment, being electrically driven throughout. The new operation is looked upon as a big boon to Shickshinny.

Pittston—Eighty mine workers from from the Pittston district are to receive first-aid instructions from the Federal Bureau of Mines. One of the mine-rescue cars arrived in this city recently, and is stationed near the Erie depot. It is in charge of Daniel D. Davis.

Tennessee

Briceville—The output of the Cross Mountain mine of the Knoxville Iron Co., in which an explosion occurred last December, killing 84 men and imprisoning 5 more, has been increased to 200 tons per day. It is working now full time and is employing all of the miners who apply. More could be used. The mine and the village of Briceville are just now beginning to assume their normal attitude.

West Virginia

Fairmont—It is said that with the opening of spring, 1500 men will be brought into this section to mine coal. Several mines that have been closed down lately will resume work and the outlook in the coal industry for this section is exceedingly bright. The additional men will work in the mines of the Consolidation Coal Co.

Wheeling—A big deal in Marshall County coal is said to be pending between the owners and J. W. Miller, of Mannington, who is understood to be representing the Consolidation Coal Co. of Fairmont. The coal in question is the Mapleton vein underlying 20,000 acres in the Meade district and if the deal goes through the owners will receive in the aggregate, about half a million dollars. Coal rights for the Pittsburg vein have been selling for more than $50 an acre but no sale of rights for the Mapleton vein has been reported for some time. The Mapleton seam is from 4 to 6 ft. thick and lies near the surface, above the Pittsburg seam, which here runs from 7 to 10 ft. in thickness.

McDonald—It is estimated that $2000 worth of property was destroyed by a fire, Feb. 1, in the blacksmith shop at the Jumbo mine of the Pittsburg Coal Co. The building was completely desrtoyed but will be rebuilt at once.

Mexico

Coahuila—All the mines in northern Mexico are closed down as a result of the revolution in this locality. It is also reported that the foreman and a number of Japanese miners were murdered at the Palos mine, near Muzquiz, Coahuila. American capital is heavily interested in this district.

England

London—The probability of a general coal strike on Mar. 1 and complete disturbance of the industry was greatly increased by the failure, Feb. 7, of the national conference of coal owners and miners to effect a settlement. The miners met Feb. 13, to consider the operators' refusal to grant their demands. The delegates were in a defiant mood, and a general strike seems almost inevitable.

Belgium

Brussels—Fierce rioting broke out, Feb. 12, in connection with the coal strike at Mons. Soldiers were rushed to the scene on a special train. Strikers in mobs looted much of the town, overpowering the police when resistance was made. Many were injured.

Prussia

Antonienhütte—Many lives were lost in one of the pits near here, Feb. 12. Seven bodies have been brought to the surface, and the authorities believe at least 20 more men perished. The number of men in the pit is not definitely known, but all except those in the immediate vicinity of the bottom of the shaft were cut off and are almost certainly dead.

Personals

A. M. Hartwell, president of the Berwind Fuel Co. was recently in Duluth, inspecting the company's dock and briquetting plant.

B. W. Wistar, who has been with the Goff Kirby Coal Co., Cleveland, Ohio, for the last ten years, succeeds Mr. Houston in Cleveland on Feb. 1, as sales manager for the Moreland Coke Co. at that point.

W. D. Washburn, of Minneapolis, president of the Washburn Lignite Coal Co., recently visited the company's mines at Wilton, N. D., and while there formulated plans for improvements to be made during the coming summer.

D. G. Davis, recently appointed special inspector of mines for the Union Pacific Coal Co., will leave this month for an extended trip to the company's various properties, returning later to Evanston, Wyo., where he will make his home.

David Selway, manager of the Selway Coal Co., was in Columbus recently, with a view to selecting office space, preparatory to removing the headquarters of the company to Columbus. The Selway company operates a large new mine in the No. 8 seam at Fairport, and is an important factor in the eastern Ohio field.

Charles J. Coll will return to the employ of the H. C. Frick Coke Co. as superintendent at Brownfield, after an absence of 11 years. In 1900, Mr. Coll left the Connellsville region to go to Stellarton, Nova Scotia, where he was general manager of the Acadia Coal Co. Mr. Coll now succeeds W. L. Affelder, who is leaving to take another position.

C. E. Tobey, superintendent of the coal mining department of the Delaware, Lackawanna & Western R.R. Co., and president of the Scranton Y. M. C. A. District Mining Institute, has been secured as one of the speakers at the Pennsylvania Y. M. C. A. State Convention which meets at Bradford, Feb. 22-25. Mr. Tobey will address the convention on "Present Day Evidences of Social Advancement in Coal Mining Communities."

George W. Brymer, who succeeds J. F. Hannigan as superintendent of the Edgewater plant of the Tennessee Coal, Iron & R.R. Co., has taken up his new duties at Ensley, Ala. Mr. Brymer was formerly engaged as chief engineer of the northern division, Pennsylvania Coal & Coke Co., Cresson, Penn.; as superintendent of the Jed Coal & Coke Co., Jed, W. Va., and as division superintendent for the Pennsylvania Coal & Coke Co., at Patton, Penn. He went to Alabama from Philadelphia, Penn., where he was engaged in consulting work as an assistant to E. T. Connor, mining engineer, in making several extensive examinations and reports on large mining properties.

Obituary

J. H. Shelly, aged 28, of Jellico, Tenn., was instantly killed when a motor he was testing in the No. 1 mine of the Jamison Coal & Coke Co., near Greensburg, Penn., jumped the track and crushed him against the wall. Shelly was employed by an Illinois firm and was installing electric locomotives in the mine.

Calvary Morris, coal operator, banker and capitalist, died Feb. 5, at the Lakeside hospital, Cleveland, where he had gone, on Dec. 24, to undergo a minor operation. He was well on the road to recovery when he was taken with pneumonia and later was striken with apoplexy. Mr. Morris laid the foundation for his business success at the coal mines. He was born in Athens, Ohio, 61 years ago, and gained his first knowledge of coal by weighing the product at the mines. He came to Cleveland over 20 years ago and entered into partnership with B. D. Babcock, under the name of Babcock, Morris & Co. Later he went into partnership with J. W. Ellsworth, under the name of the Morris & Ellsworth Coal Co. In 1897, Mr. Morris formed the Morris Coal Co., and later the Jefferson Coal Co and Morris-Poston Coal Co., taking an active part in the management of all three.

Industrial Notes

Monks & Johnson, architects and engineers, 7 Water St., Boston, report the complete installment of a $23,000 coal-handling equipment for J. B. & W. A. Lamper, Lynn, Mass. The plant includes a single-man discharging tower of the Boston or steeple type with cable road over the present sheds. It is stated that this coal-handling equipment, manufactured by Mead, Morrison & Co., has greatly reduced the cost of handling the coal.

The Link-Belt Co. has just closed a contract for building a large coal tipple for the McGregor Coal Co. This will be erected on Rums Creek, Logan County, W. Va. The president of this company is John Laing, who is also chief mine inspector for the State of West Virginia. The tipple will be one of the largest in this section of the country. It will be built of structural steel, sheathed and roofed with corrugated iron, and will contain car feeders, trip makers, picking bands, a double set of "Link-Belt" shaking screens, slack conveyors and conveyors for taking the slack coal to the boiler house. The Link-Belt Co. will design, furnish and erect the entire equipment complete.

The Watt Mining Car Wheel Co., Barnesvillle, Ohio, announces that Ira E. Stevens and the Stevens Mine Fan Co., Old Colony Building, Chicago, no longer represent this company, and that on and after Feb. 1, 1912, all orders and inquiries will be handled directly from the main office at Barnesville. The company is prepared at all times to give prompt attention to mine-car requirements and maintains a force of expert car men for the purpose of designing new equipment or changing the old to meet present mining conditions in the various districts.

New Publications

FOURTH ANNUAL REPORT OF THE DEPARTMENT OF MINES, OKLAHOMA. Ed. Boyle, chief mine inspector, Guthrie, Okla. 180 pp., 6x9 in.

Report is for the year ending June 30, 1911, and is devoted almost exclusively to coal mining, although the production of lead, zinc, asphalt and oil is also covered. There was produced during the year, a total of 2,569,869 tons of coal, involving the employment of 8191 men in and around the mines.

THE RATE OF BURNING OF FUSE. By Walter O. Snelling and Willard C. Cope. Technical Paper No. 6, U. S. Bureau of Mines. 28 pp., 6x9 in.

The safety of a miner in his daily work depends to a great extent upon his ability to gage with reasonable accuracy the time that a certain length of fuse will take to burn and ignite a shot. Misfires and retarded shots, with their accompanying dangers, are largely due to defective or improperly handled fuse. Inasmuch as tests made by the authors of this report show that an ordinary fuse with a normal rate of burning of from 25 to 30 sec. per ft. may, under certain conditions, burn as fast as 1 sec. per ft. and, under other conditions, as slowly as 227 sec. per ft., the importance of keeping fuse from unfavorable circumstances of storage and use at once becomes apparent. Under ordinary conditions, nearly all types of fuse were found to show great uniformity in their rate of burning, but under the influence of pressure the rate was found to increase, in at least one instance, from a normal value of 28 sec. per ft. to something over 6 sec. per ft. Similarly, high temperatures were found to have a retarding effect and mechanical injury, due to pounding or hammering, resulted in such an increase in the rate of burning as to make it almost instantaneous. The paper gives in detail the results of tests that were conducted with the idea of investigating the effects of pressure, temperature, moisture and mechanical injury on the rate of burning of the several ordinary forms of miners' fuse.

Trade Catalogs

Howells Mining Drill Co., Plymouth, Penn. Catalog No. 28. Howells Mining Drills. 112 pp., 6½x9½ in., illustrated. A complete and profusely illustrated descriptive catalog of the numerous forms of electric, compressed-air and hand-power drills manufactured by the Howells company. Lists and prices of repair parts are given.

The Draeger Oxygen Apparatus Co., Pittsburg, Penn. Catalog R, "Oxygen the Life Saver." 212 pp., 5¾x8¾ in., illustrated. This volume contains in addition to a complete, detailed and well illustrated description of Draeger rescue apparatus, a number of interesting and valuable notes on the general subject of oxygen breathing devices, the construction and equipment of rescue stations and instructions for rescue brigades. Five pages are devoted to listing old and recent literature on the subject of breathing apparatus.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

Coal supplies are reduced to a point where the situation is acute. In spite of the utmost efforts of the railroads, the movement has been below the consumption for some time, and actual suffering is now in evidence at some centers. Spot coal can be had only at fancy prices and many large steam users can get only sufficient fuel to keep their plants from freezing.

In the East at some anthracite-burning cities, a number of dealers have been supplying their customers with soft coal, and even wood. It is believed that six weeks of uninterrupted work at the mines would be required to fill orders now on hand, and some new record prices for this grade have been quoted. The cold weather has so crippled the railroads that they are in many instances concentrating their entire efforts on the movement of perishable freight, and entirely neglecting the coal tonnages.

Considerable suffering is being experienced in Michigan and northern Indiana and Ohio, with mines in the latter state getting only sufficient cars to work about 25 per cent. capacity. Unusually cold and stormy weather has prevailed in that territory and the railroads appear utterly incapable of handling the situation. In the South the demand is reported heavy, with prices hardly quotable and the situation bordering on a coal famine at some points.

Railroads appear to be catching up on deliveries to a certain extent in the Middle West, with the exception of the Illinois Central, whose mines are working only one day a week. Heavy storing by the large transportation systems continues, especially the New York Central who, it is claimed, are laying in supplies to the extent of a quarter of a million tons.

In direct contradistinction to the East, the far West appears to be experiencing an unusually mild winter, with the result that the markets are quiet and dull.

Boston, Mass.

New England is still short of coal, and to say that consumers and dealers are worried over the outlook would be putting it mildly. In a number of ports to the Eastward the dealers are out of anthracite and are supplying customers with wood and soft coal. In Calais, Me., several cargoes from the Spring Hill mines, Nova Scotia, have been received for distribution through this section. The Boston dealers are able to get broken, stove and chestnut only in hand-to-mouth shipments, and at Providence the shortage is such that fancy prices are offered for prompt delivery.

All-rail, both bituminous and anthracite, are coming through slowly, and operators are slow about committing themselves ahead. Water freights have advanced; $1.30 was paid on 2500 tons, Baltimore to Boston, and $1.25 is asked from Hampton Roads.

Current prices are about as follows:

Clearfield, f.o.b. mines	$1.25@1.45
Somersets, f.o.b. mines	1.35@1.55
Pocahontas, New River, Boston, on cars	4.50@4.75
Pocahontas, New River, Providence, on cars	4.35@4.50
Georges Creek, f.o.b. Philadelphia	2.67@2.85
Pocahontas and New River, f.o.b. Virginia terminals	2.70@2.80

New York

The supply of soft coal at the New York piers continues extremely short. The demand on contract is heavy and with the continuance of a short car supply and slow railroad movement, shippers are hard put to take care of their New York Harbor obligations. There is a good deal of spot inquiry from consumers who are anxious to stock in anticipation of labor troubles and this, coupled with the cold weather, keeps the market quite firm. Prices are somewhat stronger than last week, with the cheaper grades of coal scarcer and the better grades practically unobtainable except on contract. West Virginia steam coals are quite firm at $2.65 f.o.b., while ordinary Pennsylvanias are held at from $2.70 to $2.75 f.o.b.

The loading piers continue to be handicapped because of the frozen condition of the coal and the delay in loading averages about three days. Towing conditions to the lower ports are extremely hazardous on account of ice in the river, making it difficult to get boats down to and up from the piers.

The stocks of all-rail consumers, owing to slow railroad movement, are gradually being reduced and from these consumers, more inquiry for extra coal is being received.

In the Sound ice conditions are extremely bad for marine transportation; at the Sound terminals scarcely enough coal is being received to take care of the demand, and there is a ready market there at good prices for any extra coal shippers have.

Philadelphia, Penn.

Seasonable weather still continues in this vicinity, and conditions as far as the retail trade is concerned, show no marked falling off. In fact, the demand is even better, and the supply is far from adequate. Temperature remains low, and as a consequence, the fires are kept going at top speed, the added consumption bringing increased business to the retailer. All sizes are moving off far more promptly than the dealers are able to replenish their stocks. Stove, chestnut and pea are far behind the market. As high as $2.50 at the mines has been offered for pea coal, and even at this record figure, orders are being turned down. The situation is certainly growing critical.

As it stands at present, the output of the mines, brought to the market by the wholesale operators, is not beginning to supply the demand, which is far in excess of the production. From broken to the steam sizes of pea, buckwheat and rice, orders are far in advance of the available supply, and work at the mines for six weeks at full pressure will not begin to cover the orders already entered. A car or two on orders for twenty or more of any size, are thankfully received, for most of which they pay better than the circular price. The meeting of the anthracite operators and miners' representatives takes place on the twenty-seventh of the month, and is likely to add additional complexities to a situation already desperate.

Pittsburg, Penn.

Bituminous—There have been no important developments in the wage-scale matter, and there is no likelihood of any approach to a settlement being made in the near future, as the situation can hardly be righted without a suspension of mining for perhaps six weeks. Stocking of coal by consumers is unavoidable and it will be necessary for the safety of the market to allow these stocks to be worked off. On the other hand, the prospects are for a large demand in the lake trade, stocks being light in the Northwest, and a suspension longer than six weeks from Apr. 1 would encroach upon the navigation season.

Demand continues good locally, both manufacturing and domestic, and mines are running as well as they can considering weather and transportation conditions. There is a fair supply of cars, but the coal moves slowly, on account of

extremely cold weather. Full prices are readily obtained. We quote: Nut, $1.05@1.10; mine-run, $1.10@1.15; 3/4-in., $1.20@1.25; 1 1/4-in., $1.35@1.40; slack, 70@75c. per ton at mine, Pittsburg district.

Connellsville Coke—Market prices show no change, but coke is a trifle easier to obtain. Sales of between 150 and 175 cars of prompt furnace have been made in the past week. Prompt foundry coke is about 5c. higher. We quote: Prompt furnace, $1.80@1.90; contract furnace, $1.80@1.90; prompt foundry, $2.20@2.30; contract foundry, $2.20@2.40.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Feb. 3 at 360,153 tons, a decrease of 40,000 tons, and shipments at 4052 cars to Pittsburg, 5592 cars to points West and 979 cars to points East, a total of 10,623 cars, a decrease of 500 cars.

Baltimore, Md.

Another spell of almost zero weather created an active market in the coal trade of Baltimore last week. The operation at the mines in both West Virginia and Maryland was seriously interfered with, thus reducing the output. Consumers appeared willing to pay almost any price for coal, but even at the higher prices, they were unable to procure any big supplies.

The higher prices for coal and the continued active demand has been the means of raising the hopes of the trade here. Jere H. Wheelwright, president of the Consolidation Coal Co., during the past week, spoke most optimistically over the future outlook for the coal trade. He stated that he believed that 1912 would be a splendid year for the coal business, and that he based his opinion on the large number of orders which his company had already booked for delivery. The market, at the present time, he further added, was in better shape than it had been for a long period.

The coke market continues active. Most of this product has been for consumers who made inquiries two or three weeks ago. Numerous inquiries were received during the past week, and the actual business done showed an increase over the previous week.

Buffalo, N. Y.

The coal situation here is fast growing distressing. There is difficulty with anthracite, on account of the enormous demand and the drawbacks to production and in both anthracite and bituminous alike the movement by rail is decidedly alarming. The railroads are swamped and every day reports come in that more of them are refusing to make the effort to move the nonperishable freight offered them. Shippers say that they have loaded coal cars extending all the way around Buffalo, from East Buffalo to Black Rock, chiefly for shipment to or through Canada, but are getting less and less service every day.

The situation Eastbound is quite as bad as it is West or North, for the New York Central is so blocked with cars that it cannot move and connecting roads, finding that their deliveries merely pile up at junction points, implore shippers not to route anything by that road if they can help it. This section and to the limit in all directions has seen nothing but severely freezing weather since the second day after Christmas and the mining regions are still colder, so that production is slow and has now become less than the new orders that come in.

Manufacturers are begging for a little bituminous so that their works will not freeze up and suffer from ice, but shippers can do very little but urge the roads to some sort of fresh activity. Buffalo is so far well enough supplied, as the mines are not far away and the coal roads are not badly congested.

Soft-coal prices are hardly quotable. All shippers are getting a 10c. advance and most of them could get almost any price in some instances if they could insure quick deliveries. For the present Pittsburg quotations remain at $2.60 for three-quarter; $2.50 for mine-run, and $2.25 for slack, with coke $4.25 for best Connellsville foundry and $3.50 for stock.

Cleveland, Ohio

Unusually cold and stormy weather has resulted in a continuous good demand for domestic, as well as steam coal, with prices firm. Many mines in Ohio, Pennsylvania and West Virginia are closed on account of frost, and in consequence markets in this vicinity have not been over congested. Everything in the way of coal of all grades is well and promptly taken care of, car service being at a premium during the past week. Slack that was a drug on the market last week, has been well cleaned up with the returning of high prices that prevailed during January.

Prices range as follows:

Cambridge	
Mine-run	$1.10
3/4-in.	1.20
1 1/4-in.	1.35
Slack	$0.95@1.00
Ohio No. 8	
Mine-run	$0.95@1.00
3/4-in.	1.05@1.10
1 1/4-in.	1.25@1.35
Slack	0.85@0.90
Ohio No. 6	
Mine-run	$1.10
3/4-in.	1.20
1 1/4-in.	1.30
Slack	$0.85@0.95

Columbus, Ohio

Demoralization still continues in the coal trade in central Ohio and railroads are utterly incapable of coping with the situation. The trouble takes two distinct forms, the lack of motive power of railroads which makes it impossible for the connecting roads to move coal from junction points, and the acute car shortage caused by the tie up of so many cars at way points.

As a result of this condition considerable suffering is reported from Michigan, northern Ohio and northern Indiana points. Probably the greatest trouble is in Michigan where many factories have been compelled to close down and permit the small coal supply to be used for domestic and heating purposes. Reports show about 8000 loaded coal cars at Toledo awaiting movement into Michigan and the connecting roads either unable or unwilling to complete the haul.

As a result of the car shortage, mines in every section have been running on very limited time. The output is less than 25% of normal and in many cases mines have been closed down the entire week. Operators are able and willing to increase the production if only cars were available.

Retail trade has been active during the past week and customers are demanding immediate delivery. In Columbus and immediate vicinity the supply is adequate and little suffering is reported. Ice has caused some trouble in making deliveries. Prices are firm on all grades.

Prices prevailing in Ohio mining districts are as follows:

Domestic lump in Pomeroy Bend district	$1.65@1.75
Domestic lump in the Hocking Valley	1.50
Three-quarter inch	1.35
Nut	1.15
Mine-run in eastern Ohio	1.00@1.05
Mine-run in the Hocking Valley	1.05@1.15
Nut, pea and slack	0.80@0.90
Coarse slack	0.65@0.75

Cincinnati, Ohio

It is doubtful if this market has seen such a combination of favorable and unfavorable conditions continuing for so long a time in many years. During the extremely cold weather in January the river coal interests were almost tied up tight by a frozen river, which prevented the movement of barges in the harbor.

The cold weather and heavy snows, not only in the mountains, but here also are credited with being responsible for the unfortunate car situation. Several of the coal roads are putting down and taking up embargoes on all Western movements so rapidly that the mines have hard work keeping track of them. Reports from other cities in the state indicate that conditions are not much better there. The continued ice and snow on the streets are responsible for the added cost of wagon deliveries in the city and suburbs.

Demand is just about the same as it has been for several weeks, nut and slack being the strongest with prices at 85c. to $1 and the tendency upward. The demand for lump coal is holding up un-

der the continued cold weather. The average temperature since the first of the year has been around 20°, with long stretches of zero weather.

Charleston, W. Va.

Except for a modification of weather conditions there has been no change in the coal situation in this section of the state during the past week. The milder weather has permitted a freer handling of cars, both loaded and empties, but normal conditions have by no means as yet been restored. Prices have not suffered on account of the improvement in shipping conditions and in some circles a belief prevails that there will be no drop back to where they were before the cold weather interfered with shipments.

West Virginia operators anticipate no labor troubles this year. The state went through the past year without a strike except for local difficulties lasting a few days at several mines. With the indications of trouble in other states, the West Virginia operators have hopes of being able to maintain a condition that will be of benefit to them in a financial way.

Memphis, Tenn.

Memphis has had one of the best coal-selling periods of weather that the coal dealers can remember. January saw the greatest tonnage of retail coal handled by dealers for any one month in our history. February has also opened up with fine prospects for a big business.

This good weather and good sales have made the wholesale market exceedingly stiff. To add to the weather conditions, we have had a shortage of cars both in Alabama and east and west Kentucky. These are the places from which Memphis has drawn most of its coal.

The Illinois Central R.R. is still tied up in their strike, which has certainly handicapped Memphis and all the territory south during this continued period of cold weather. The mines' prices have been stiff at $1.50 for Kentucky lump.

Illinois has, for the last few weeks, practically withdrawn from this market, as they are unable to make shipments over the Illinois Central R.R. It has been impossible for the brokers and dealers to secure anything like sufficient quantity of coal from the mines to take care of the trade that has been offered.

Prevailing prices are as follows per ton:

Nut	$1.00@1.25
Mine-run	0.85@1.00
Alabama lump	2.25@2.50
Mine-run	$1.25
Cahaba coals	2.75@3.00

Nashville, Tenn.

This district is in the midst of another spell of cold weather, together with a car shortage which has prevailed for the past several weeks.

The demand for coal has been greater than ever and for spot shipments, big prices have been offered for all grades. It has been many years since the cities and towns in this district have been as bare of coal as they are at the present time. It has been a desperate situation for the past few days, and there is nothing that can save it except a spell of warm weather which we are likely to have at any time. Should we go into the coming week with very cold weather, a famine will be the result.

Prices vary considerably and it is rather hard to quote, but they range about as follows:

Standard lump	$1.50@1.75
Standard nut	1.00@1.10
Standard screenings	0.30@0.40
Mine-run	1.00@1.10

Indianapolis

The steady cold weather during the past week caused a corresponding increase in the demand for domestic coal. While the railroads succeeded to a certain extent in catching up with deliveries, coal famines were reported at a number of points, necessitating the closing of school and other public places. The cold weather caused a lull in other traffic which permitted the railroads to concentrate their efforts on moving fuel and they were able to move practically all the coal mined.

Although the extreme cold weather and enormous consumption is thought to be over in this state, the sidetracks have become congested along the lines seeking to reach the Northern markets. This, however, is expected to clear up within the next few days. In the meantime the numerous orders coming from the Indiana dealers indicates that the next month will see vast piles of coal stored in preparation for a cessation in mining. It is given out that not in years have large consumers been so near the bottom of their storage piles as at present.

Chicago

Prices in the Chicago coal trade have stiffened in some directions. The belief is prevalent that there will be a suspension of the mines Apr. 1 and large consumers are attempting to acquire a surplus stock sufficient to tide them over until May.

Some dealers are inclined to believe that the prospective tie-up of the mines will last until midsummer and are advising customers to prepare for a suspension of that duration. The statement is made on good authority that the New York Central road is storing a quarter of a million tons of coal at Harrisburg, Ill. Prices for screenings still remain strong, and it is expected they will continue so until the present unsatisfactory operating conditions on the railroads have been remedied.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.87
Egg	2.87
Steam lump	$2.37@2.57
Screenings	1.97@2.07
Springfield:	
Domestic lump	$2.67@2.82
Steam lump	2.17@2.27
Mine-run	2.07@2.17
Screenings	1.92@2.03
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.22@2.32
Mine-run	2.17@2.27
Screenings	1.87@2.00
Pocahontas and New River:	
Mine-run	$3.25@3.55
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.65@4.75; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $4.90@5.

St. Louis, Mo.

The market opened up strong the beginning of the week, following a slump the latter part of last week, especially in the Standard sizes. There has been a good demand during the past week for railroad coal, and a large tonnage of this is moving in equipment furnished especially for that purpose from the Standard field. All the railroad companies are laying in storage coal, and considerable of this is moving from the Springfield district, as well as the Standard, while but a small tonnage is moving out of the Carterville field. This is largely accounted for by the fact that the Illinois Central have no motive power even though they are receiving 50 new locomotives at the rate of one per day. The Iron Mountain has about all it can take care of at the present time.

Steam business in St. Louis and the country has put the market in good shape and all plants are preparing to store coal, several of them having already started. The same applies to several of the larger retail dealers, and it is taken for granted here that there will be a suspension in the Illinois field of at least three months, and possibly five.

Conditions on the Illinois Central seem to be getting worse, and the mines on that road are only working about one day per week. The Frisco Lines are doing better, as is also the Iron Mountain, with the exception that they are taking the larger part of their equipment for company coal. Indications are that the market on all grades will remain firm, with a tendency to move upward.

The higher-grade coals from the Inner district have been in remarkably good demand for country business, and the Mount Olive coal field is pretty well oversold. There has been an exceptionally good demand and a fair movement of anthracite at circular prices, also both byproduct and gas-house coke at $5.90 for the former and $4.75 for the latter has been hard to get. The smokeless market is in good condition.

The prevailing prices the early part of the week were as follows:

Franklin County	
Lump and egg	$2.15@2.25
No. 1 nut	2.00@2.15
No. 2 nut	1.75@1.85

Salt Lake City, Utah

Owing to the mildness of the weather the demand for coal is diminishing. All mines are well up with their orders, and the retail trade is quiet. The Denver & Rio Grande R.R. has placed orders with independent companies for 10 to 12 cars daily. This is a new departure in the policy of the railroad company and is taken to indicate that the Utah Fuel Co., a subsidiary organization of the Denver & Rio Grande, is conserving its own supply.

Mine prices are as follows: Lump, $2.40@2.75; nut, $2.15@2.25; slack, $1.75.

Spokane, Wash.

The weather here has moderated to such an extent that almost no coal is being sold, the supplies in the basements being ample. It is not thought that Spokane or the Inland Empire will experience any more severe cold weather this winter, and in some places the spring flowers are coming up. Furnaces are still in operation, however, but are being supplied by wood as far as practicable. Prices are inclined to fluctuate enough to stimulate trade by some of the dealers, while the majority are holding to the regulation price.

The prices of standard coals for the week ending Feb. 7, were as follows:

	Wholesale	Retail
Rock Springs	$7.20	$9.00
Owl Creek	7.20	9.00
Kirby	7.20	9.00
Carney	6.70	8.50
Bearcreek	6.25	8.25
Roslyn steam	5.25	6.25
Canadian steam	5.25	6.25

Portland, Ore.

The market situation remains practically unchanged, the demand for coal being light owing to mild weather. Oregon has enjoyed a very favorable winter and in consequence the demand for fuel has not been heavy. The demand for coal for manufacturing purposes shows no material fluctuation. The ruling price for Australian and Wyoming is $9.50, including cost of delivery within the city proper.

Production and Transportation Statistics

The Car Situation

The fortnightly bulletin of the American Railway Association states that on Jan. 31 the net surplus of idle cars on the lines of the United States and Canada stood at 32,581, compared with 90,285 two weeks before, a difference of 57,704.

The decrease in the number of idle cars was most noticeable in the coal-producing sections. But almost every part of the country has experienced great difficulty in moving cars, owing to the extreme cold.

Chesapeake & Ohio Railway

The following is a statement of the coal and coke traffic over the lines of the Chesapeake & Ohio Ry. for December and 6 months ended Dec. 31, 1911, in short tons:

Destination	December	6 Months
Tidewater	367,310	1,970,464
East	200,383	1,069,419
West	937,089	5,735,771
Total	1,504,782	8,775,654
Coke	17,557	110,597
From Connections		
Bituminous	23,404	117,326
Anthracite	3,338	18,749

Anthracite Supplies

Stocks of coal at tidewater were 521,283 tons on Jan. 31, 1912, as compared with 712,958 tons on Dec. 31, 1911, a decrease of 191,673 tons. The stocks at tide are lower than for years. It is generally estimated in the trade that the consumption of coal in January was 50% above the average. The actual consumption on the known figures in the month was nearly 6,000,000, but it was no doubt considerably more than this.

Anthracite Shipments

Comparative statement of anthracite shipments for January 1911-12 is as follows in long tons:

	1911	1912
Philadelphia & Reading	1,134,280	1,186,534
Lehigh Valley	1,021,447	1,020,447
Jersey Central	772,130	760,035
Delaware, Lack. & West	863,371	791,698
Delaware & Hudson	611,758	567,279
Pennsylvania	591,917	542,819
Erie	678,531	682,845
N. Y., Ontario & West	230,683	212,039
Total	5,904,117	5,763,696

Foreign Markets

Great Britain

Buyers continue to adopt a waiting policy pending further developments in the labor situation, and large coal prices are easier for both prompt and forward loading. Small coals are steady, with an upward tendency. Quotations are approximately as follows:

Best Welsh steam coal	$4.62@4.74
Seconds	4.44@4.56
Thirds	4.14@4.38
Best dry coals	4.26@4.38
Best Monmouthshire	4.20@4.26
Seconds	3.96@4.02
Best Cardiff small coals	2.58@2.64
Seconds	2.40@2.52

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those of Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½% discount.

Nova Scotia

Coal production of Nova Scotia, by companies, for year ended Dec. 31, 1911, was as follows:

Dominion Coal Co. (Glace Bay)	2,469,493
Nova Scotia Steel & Coal Co.	784,969
Acadia Coal Co.	278,131
Intercolonial Coal Co.	249,218
Inverness Ry. & Coal Co.	230,752
Dominion Coal Co. (Springhill)	216,325
Other companies	368,743
Total	4,597,631

Financial Notes

Gross earnings of Lehigh Coal & Navigation Co. for year ended Dec. 31, 1911, were $13,733,777, an increase of $1,091,664; net earnings were $5,534,793, an increase of $390,272; surplus was $681,174, an increase of $368,874.

The Boston Stock Exchange has recently listed 150,000 shares of the Pond Creek Coal Co. Authorized capital is 200,000 shares, par 10, of which 150,000 are issued. Stock is quoted at between $16 and $17.

Gross earnings of Huntingdon & Broad Top Mountain R.R. & C. Co. for year ended Dec. 31, 1911, were $538,730, a decrease of $133,507; operating expenses were $425,831, a decrease of $86,014; net, $113,898, a decrease of $27,494. Directors were reëlected at annual meeting.

The syndicate to underwrite bonds to be issued under plan for merging Alabama Consolidated Coal & Iron Co. and Southern Iron & Steel Co. has been completed. The new company, to be known as the Alabama Consolidated Iron & Steel Co., is to have a total capitalization of $33,986,000.

Lehigh Coal & Navigation Co. earned 10.2% on capital stock for year ended Dec. 31, 1911. Surplus available for dividends is $2,709,370, showing a gain of $465,326 over the best previous record. Gross revenues from all sources, $13,733,777, an increase of $1,091,664 over previous year.

January bonus awarded to the anthracite workers by the United States Commissioner of Labor amounted to 7% of their month's pay, and with the flat increase in wages of 10% allowed to the men by the Strike Commission of 1902, makes their rate of pay in January 17% higher than the wages prevailing before the Roosevelt Commission brought the operators and their men together. The total benefit to the mine workers from the bonus system has amounted to $30,000,000 since 1902. This is aside from the 10% flat increase in wages.

Williams Coal Crushers, By Maintaining Grinding Diameter, Insure Permanent Uniformity Of Product

And this advantage of the Williams Crusher has proven of great value to the Coal and Coke Trade.

It is obtained by the extreme adjustability of the machine which makes every part adjustable, not only to itself and to wear, but also to every other part.

Thus, Hammers are adjustable to Breaker Plates and Cage. Cages are adjustable to Hammers. Breaker Plates are adjustable to Hammers.

By these adjustments not only is uniform product insured at all times despite wear, but also life of the grinding parts is prolonged, cost of maintenance is lessened, capacity of crusher is increased, and the horsepower per ton crushed is decreased.

In fact, Williams Patent Hinged Hammer Coal Crushers can crush more coal with less power and less cost of maintenance than any other crusher made. In safety and ease of operation they are unexcelled. *Write for Catalog No. 5 with full information.*

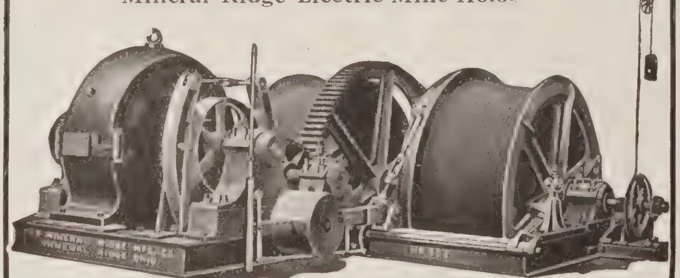
Mineral Ridge Electric Mine Hoist



Efficient And Reliable Under Any Conditions

Mineral Ridge Mine Hoist

Because of their *reliable* efficiency and their lasting efficiency, Mineral Ridge Hoists are suited to give most satisfactory service under any mine conditions.

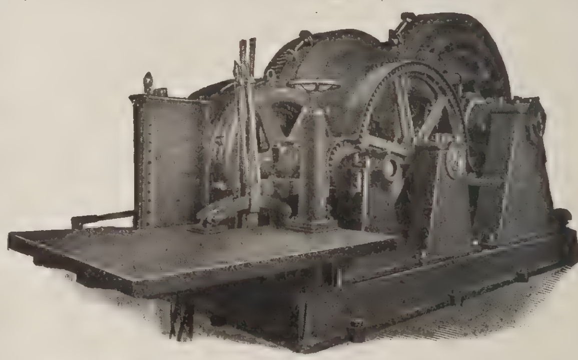
They are so arranged that they can be operated from a distance, or can be made entirely automatic in action. Easily controlled, have a very low operating cost, and are perfectly safe at all times.

You will find that Mineral Ridge Hoists, either steam or electric, will answer your hoisting requirements in the most satisfactory manner.

Write for the full particulars.

**THE MINERAL RIDGE MFG. COMPANY
MINERAL RIDGE, OHIO**

Vulcan Hoists



THESE are the hoists of proved reliability. They have been tested under every condition of mine service and found efficient.

Besides both Steam and Electric Hoists, we build Coal Crushers, Mine Locomotives, Elevating and Conveying Machinery, Screens, Tubular Boilers, etc.

Wilkes-Barre, Pa.

COAL AGE

Vol. 1 NEW YORK, FEBRUARY 24, 1912 No. 20

THERE is always some incentive back of every worth-while effort. Success may be due to the force of a good example; it can result from the steadying influence of sound advice; or, again, necessity often compels the individual to exert his powers so frequently that habits of industry are formed, and in accord with a fortunate arrangement in the mental and moral economy of our nature, that which is performed as a duty soon becomes a habit, and the action of the human being is determined for good.

The best support of character is the exercise of the will, and this is the habit most essential to cultivate. When the will is weakened, the trained nerves continue to repeat the daily acts, even when the doer abhors them. What we at first choose, at last compels, and the threads we weave each day soon form a cable which cannot be snapped. There is no greater truism than "the chains of habit are too small to be felt until they are too strong to be broken."

What a man will do in any emergency, whether it is a mine fire, an explosion, or other disaster, is determined almost wholly by his first unthinking impulse, and the latter depends entirely on the habits of the individual. From earliest youth, our best and most lasting instruction consists in habits, not in reasonings; in examples, rather than in direct lessons.

It is therefore a fact that habit has most to do in shaping our lives, and "force of example" is the chief influence in the determination of habit. Precept may point the way, but example is silent, continuous, forceful instruction, operating imperceptibly, but with absolute certainty.

Believing it is the influence of acts, more than words, that molds and shapes human character, we will commence in March to publish in Coal Age each week a study of the career of some one successful coal man. Supplementing each biography, will be an interview giving the opinions of the subject of the sketch on important coal-mining problems, thus making each account a story of much technical value.

Furnishing the world's fuel has grown to be a monster industry, and the men who have advanced the art of mining to its present state overcame difficulties in a way that is worthy of record. The sketches will be written of men who are at present in the thick of of things—the ones who, through merit, have pounded their way to the front, whether they started from a room in a mine or a room in a college.

Although we will treat only of men who have so far succeeded in life, it must be understood that we realize failure has its Plutarch as well as success. It is doubtful, however, whether failure is an object that ought to be set before us. Nothing is so easy to learn as "how not to do a thing"; it needs neither effort, teaching, perseverance nor judgment. Of course, the best of us may fail, and failure in a good cause is honorable, while success in any bad cause is merely infamous; however, success in the good cause is undoubtedly better than failure.

In conclusion, we desire to say that this new department, "*WHO'S WHO IN COAL MINING*," will be created for the sole purpose of elevating the man, and thereby the industry, through the influence of human example and practical advice. Many a foreman, superintendent or engineer whose face is pointed in the right direction, but who is daunted by present difficulties, would hesitate no longer in getting a fresh grip if only the incentive was there. Most of us need to be reminded that "Any Man Can Do What Any Other Man Has Done."

The Trinidad District in Colorado

By F. W. Whiteside*

This is the first of two articles describing coal operations in southern Colorado, one of the most important districts in the West. This initial description covers the geology, power plants and haulage systems.

The Trinidad field is a portion of a large coal-bearing area lying along the Front Range in the southern part of Colorada. It extends from the state line on the south to the north line of Las Anomas County, a distance of 30 miles, and from the east exposure of the Front Range, west to the foot of the Sangre de Christos a distance averaging 22 miles. The field contains about 425,000 acres.

General Conditions

Trinidad, a flourishing town of 12,000 inhabitants, is the commercial center of this district. The Atchison, Topeka & Santa Fe, the Denver & Rio Grande, the Colorado & Southern, the Colorada & Wyoming and the Colorado & South-Eastern railroads all enter here. These railroads and their branches handle the entire output of the district. A small percentage of the coal mined is hauled directly to the consumer by wagon from the mines. All the larger properties load their coal directly into railroad cars.

South of an imaginary line extending west from a point about midway between Ludlow and Lynn all the coal mined will make coke of high commercial value. Large quantities of this product are shipped to the steel works of the Colorado Fuel & Iron Co. at Pueblo, to various copper properties in Arizona and Mexico, to a number of smelters, to a rapidly increasing number of gas-producer plants in Colorado and New Mexico and to a large domestic trade in the larger cities of eastern and central Colorado.

*Chief engineer, the Victor-American Fuel Co., Denver, Colo.

North of this line the coal, although still bituminous in character, will not coke successfully. This characteristic adds to, rather than detracts from, its value as a steam coal, as the non-coking coals are certainly superior for firing purposes.

Generally speaking, the market supplied with coal and coke from the Trinidad district embraces New Mexico, Texas, Oklahoma, Kansas, Nebraska, Mexico and Colorado. By this statement, it is not intended to convey the idea that all the coal and coke used in the above named states is mined in and shipped from the Trinidad district. There are other coal-producing districts which ship into the same territory, but the Trinidad coal holds an important place in the these markets. That the district supplies a great volume of the locomotive fuel used by the large trunk lines which enter the state is a fact which plays an important part in governing the production of all its mines.

Geology

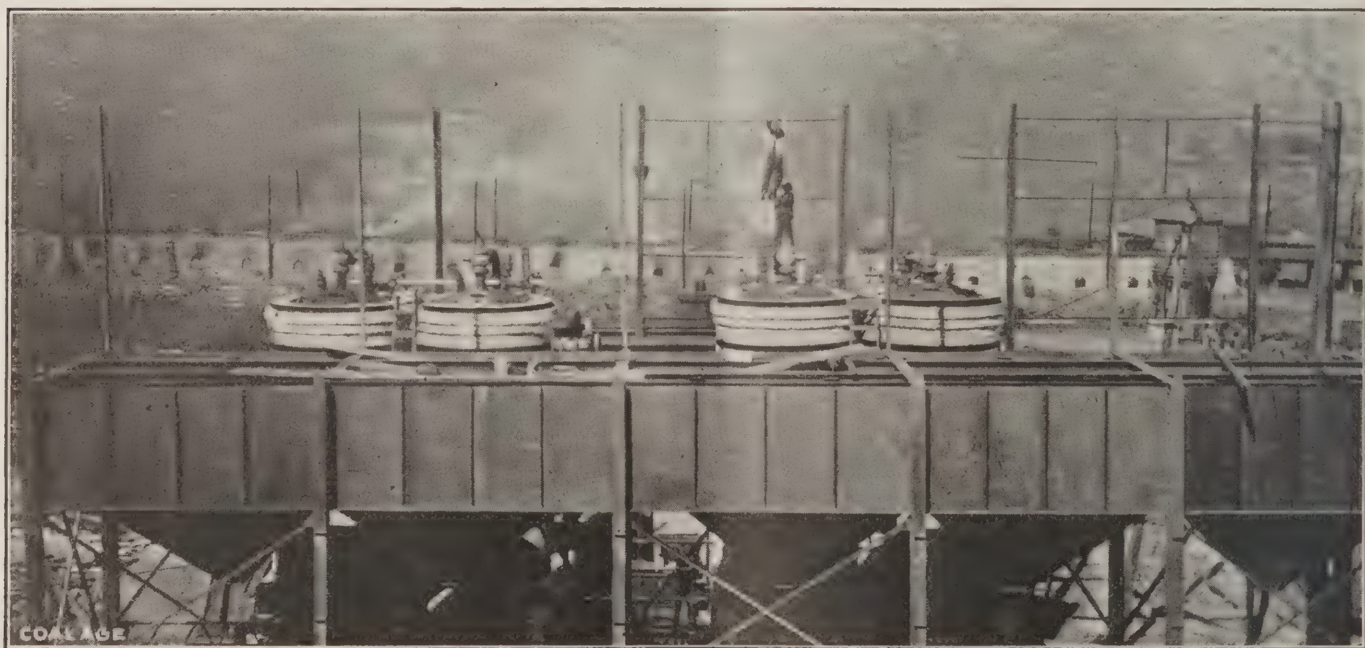
The Trinidad field is a part of the Raton Mesa Coal region, being separated from what is generally known as the Raton field in New Mexico by the Colorado-New Mexico state mine, each town giving its own name to its particular field.

All the coal-bearing regions along the Front Range in eastern Colorado, namely, the Denver, Colorado Springs, Canon City, Walsenburg and Trinidad districts belong to the Laramie formation and lie between five and nine thousand feet above sea level, those in the Trinidad field being between six and nine thousand feet.

The various coal seams are usually identified according to their distance above the Trinidad or Basal sandstone, which underlies all the coal measures in this district. Its thickness varies from 150 to 250 ft. Under this sandstone deposit is found the Pierre shales with a thickness of about one thousand feet.

The Laramie, or coal formation, rests upon the Trinidad sandstone and varies in thickness from one to three thousand feet. It consists of alternate layers of feldspathic sandstone and clayshale, with workable coal seams intersperced with considerable irregularity.

Igneous rocks occur in great quantities in certain portions of the field, proving that the region at some time must have been the scene of great volcanic activity. The intrusion of Fisher and the Spanish peaks undoubtedly destroyed vast areas of valuable coal. In many



Coal Bunkers for Central Power Plant at Hastings

localities, great masses of igneous rock have been intruded into the strata and large deposits of lava are found.

Igneous Intrusions

With the intrusion of the Spanish Peaks, a great system of dikes was formed which radiate from the peaks like the spokes of a gigantic wheel. Certain of these dikes may be traced in an easterly direction for many miles. They are usually vertical or very nearly so and their effect upon the coal is extremely varied. In most cases, aside from the expense of cutting through the dikes and the possible change necessitated in the plan of room or entry driving, they cause but little harm; the adjacent coal is not often coked to a serious extent and its bedplane will be found unaltered. Often the quality, hardness, and friability of the coal seam will be altered after passing through the dike.

It also happens that a dike will be encountered of from 100 to 150 ft. in thickness with something like an equal amount of coked coal on either side. This necessitates driving about 400 ft. of dead entry which on account of the extreme hardness of a great portion, especially the core of the dike, will cost the operator sometimes as much as $20 per running foot.

An instance is on record in the district where two seams of coal both reached a dike and passed through it, the quality of each being reversed upon reaching the further side. While this instance is not the rule it is not an extreme occurrance, and the operator who happens to be working a good seam is always far from pleased when an entry encounters a dike.

Perhaps the most serious intruder in the coal seam is the sill, a great system of which originated with the dikes in connection with the intrusion of the stocks of Fishers and the Spanish peaks. These lie nearly parallel to the plane of the coal seam, are composed of very hard igneous rock and while usually of a thickness of only one to three feet, are often of great extent. The adjacent coal is coked and large areas are made unworkable.

In the immediate neighborhood of Fishers Peak, the result of considerable volcanic action is noticible. A number of dikes and faults are encountered and in the case of one upthrow, in particular, the coal seam is displaced 110 ft. at its maximum throw. The great lava flows of this region evidently occurred far above the coal measures, but nevertheless had a marked effect upon them, although probably to a much less degree than in the immediate vicinity of the Spanish Peaks.

Bins, Boilers and No. 1 Turbo-generator at Hastings Power Plant

The Coal Horizons

Along the eastern out crop the coal seams pitch in a direction slightly south of west with an inclination of from 2 to 18 per cent. The mines here are, with two exceptions, slope and drift openings. In the valley of the Purgatoire, the measures lie nearly horizontal —and operations are carried on by drifts. Along the western boundary of the deposit the measures are turned up on edge and a pitch of from 45° to 90° is the rule rather than the exception. As the last mentioned portioned of the field contains no commercial mines the character and pitch of the measures have been determined only by preliminary surveys and small prospects.

The workable coal is found in three principal zones or measures, of which the lowest is the greatest in extent and has been the most thoroughly covered with mines and prospects. It extends above the Trinidad sandstone through a distance of approximately 250 ft. Above this measure is found a barren zone of between 125 and 325 ft. in thickness, containing no known workable beds in that portion of the district where mining has been carried on. The exact extent of this barren zone is a fact yet to be determined.

The middle measures occur next and they comprise a zone of about 200 ft. in thickness. Between the middle and upper measures a second barren zone is found which has a thickness varying from 140 to 340 ft. A number of very thin coal seams occur in this so-called barren strip, but so far as known there is no seam of sufficient thickness or good quality to be workable.

Probably less is known of the upper measure than of either of the lower. These veins outcrop still further back in the canons and are therefore more expensive to open up on account of their greater distance from the main lines of the railroads. The lower and middle measures consequently have been prospected to a much greater extent and much more is known of them.

From an economical standpoint the lower measures are by far more important, there being 32 operating mines in this formation. The minimum thickness of the seams in these measures is 3 ft. 6 in., or from 3 ft. to 5 ft. The maximum thickness of any seams yet opened, is from 5 ft. to 7 or 9 ft. while in one instance a seam has been found having a thickness at one point of 15 ft. These seams all occur at a minimum distance of between 5 and 25 ft. above the sandstone, and a maximum of between 250 or 300 feet.

In the middle measures there are only five operating companies, and the seams have a thickness of between 3 ft. 7 in. and 6 ft. 6 in.; these seams all occur between 400 or 450 ft. up to 550 or 600 ft. above the sandstone. The upper measures also have five operating mines, and the seams here vary from 4 or 5 ft. thick up to 6 or 8 ft. The upper measures occur between 740 or 790 ft., and 900 ft. above the sandstone.

Roof Conditions

The great majority of the coal seams in the district have a shale top or bottom and often both. This may vary in thickness from a few inches to many feet. When thin, the shale is usually overlaid with sandstone or in some cases with another seam of coal. A few mines are fortunate in having a hard slate or sandstone top.

As most of the shale softens rapidly upon coming in contact with the air, the proposition of timbering assumes great importance. The report of the State Inspector of coal mines of Colorado for 1909-1910 shows that, excluding the men killed by mine explosions, the total number of men killed, during 1910, in Las Animas County due to accidents was 52 out of which number 81 per cent. were killed by falls of the roof. This high percentage can be accounted for by the fact that many of the miners can not be made to understand the importance of keeping their places timbered.

The operators furnish plenty of timbers delivered at the miners places underground and the inspectors watch the timbering and do their utmost to get the men to provide fcr their own safety. When an accident occurs it is usually possible to trace the fault to the carelessness of the injured man or his partner. The lesson to be learned is that too much care cannot be given to the matter of timbering.

As few seams measuring less than 4 ft. 6 in. are operated, comparatively little brushing is necessary. The top is usually taken down, unless on account of a rolling condition of the seam, the haulage grade can be improved by taking up the bottom.

Analyses of Typical Coals

Generally speaking, the analyses of the Trinidad coals show the following: The volatiles decrease from 35.1 per cent. in the northern to 25.8 in the extreme southern part. The ash increases from a mimimum of 6.06 per cent. in the north to a maximum of 20.44 in the south of the district. Fixed carbon follows no particular rule but varies from 48.1 to 58.8 per cent.

The following table gives the average analyses of three typical coals found in this field:

ANALYSES OF COLORADO COALS

	A	B	C
Fixed carbon...	56.4	51.2	55.6
Volatile matter.	35.1	34.0	30.4
Ash	6.1	11.6	11.7
Moisture	2.4	3.2	2.3
B.t.u.	13,554.0	12,821.0	11,389.0

Sample *A* is one of the typical non-coking coals found in the northern part of the district.

Sample *B* is a coking coal from the eastern part of the field.

Sample *C* is from the southern part of the district and is one of the best coking coals found.

The foregoing may be taken as a fair representation of the coal analyses of the district. A trace of sulphur is found in all the coals, the highest percentage being 0.98 per cent. and the lowest 0.35. The highest B.t.u. value of any coal in the district is 13,981 and the lowest 11,-389, both of these being coking coals. These figures were obtained from analyses made by F. M. Stanton, of the United States Geological Survey.

Car Haul on the Cass Tipple

Feeder on Delagua Tipple

View of a Portion of the South Battery of 600 Beehive Ovens at Tercio

Power Plants

Until a few years ago, each mine operated its own power plant, but lately the tendency has been to combine the small units into large central stations. That is to say, when one company operates two or more mines separated from one another by but a few miles, a site is selected where fuel supply, quality and quantity of water together with simplicity and cheapness of ash disposal are best obtained, and a plant designed upon modern lines is installed.

The city of Trinidad has, for several years, boasted of a central power plant, which supplied light and power for the city, its local and interurban street car service, besides a number of coal properties in the district. The distributing power lines now extend as far north as Walsenburg.

The Victor-American Fuel Co. is erecting a new central plant at the town of Hastings, one of the largest producing mines, and by its use, expects to combine economy with efficient service. The equipment of this plant is patterned on the most modern lines.

The slack will be dumped from hopper-bottom railroad cars directly into steel storage bunkers, which will in turn spout the fuel into the receiving hoppers of Illinois's chain-grate stokers. The ashes will be taken from the building in buckets of a Trenton Aerial Tramway. General Electric Turbo-generators, La

Blanc Condensers, Cochran waterheaters and Stocker Cooling-Towers are included in the equipment of the plant. The buildings are entirely of concrete and steel and the plant will ultimately distribute 1500 kw. Particular mention of this plant is made, as it is one of the first of its kind to be projected by a fuel company.

The general pratice underground is to use direct current haulage and machine motors, the usual potential being 250 volts, although a number of mines are equiped with 500. The lower voltage is to be preferred on account of the saftey to men and mules. But little compressed air is used as a motive power, as the operators have found that electricity is cheaper, more easily installed and taken down, besides being more efficient. All mining machines, punchers, haulage motors, pumps, etc. are now equipped with some form of motor drive.

Above the ground, alternating current is daily becoming more popular wherever the nature of the equipment will permit its use. There is now so much alternating current circulating in the field that it is a simple matter for the operator to install an equipment which will operate with great efficiency and require little repairs. The usual voltages in service are; for long distances 23,000 and 6600; for the various units about the mines 440 and for lighting 220 and 110 with a frequency of 30 or 60 cycles.

Ventilating Equipments

Of the principal mines in the field, seven are ventilated by furnace, four by natural draught, 29 by ventilating fans and two by both fan and furnace. All the larger mines are fan ventilated, the other modes being confined to the smaller and more undeveloped properties.

A great many makes and types of fans are represented. In the majority will be found the Capell, Clifford, Crawford & McCrimmon, Jeffrey and Stein. The Sturtevant and American Blower Co. are rapidly getting into the field.

The Colorado Fuel & Iron Co. has for some time been manufacturing its own fans, at the Pueblo Steel Works and is said to be obtaining some flattering results in such tests as have been made. An American Blower Co.'s Sirocco type fan has recently been installed in one of the largest mines of the Victor-American Fuel Co. with gratifying results.

Both the force and exhaust fan is in use, the selection usually depending upon the character and arrangement of the airways and haulage entries. The practice in installing all new fans is to make them reversible although many of the old fans still operated are designed for one direction only.

Haulage Systems

On account of the great percentage of slope and drift mines, rope haulage, in its various forms is generally used. The most popular systems are the endless, the main and tail rope and the single rope gravity for the delivery of coal from the main partings to the tipple. Where grade conditions are favorable, electric haulage motors of from six to twenty tons weight deliver the coal from the mine directly to the tipple.

From the main partings the coal is brought to the tipple in a great variety of ways. At Cokedale, a powerful chain car-haul draws the cars up a steep incline to the dump. At the Cass mine, a similar chain lowers them from a parting located near the pit mouth to the tipple and a second chain-haul returns the empties to the top of the incline from which point an electric haulage motor takes them into the mine. At Wootton, the loads are taken up the grade to the dump by a cabin car-haul and the empties returned by the same means. At Delagua, electric haulage locomotives land the trips upon the car-haul at one tipple while a gravity rope performs the same operation at the other.

At Bowen, haulage motors land the loaded trips at the top of a self-acting plane, whose average grade is 55 per cent. From the bottom of the plane a second motor draws the loads to the tipple. There are many other systems which space will not permit one to mention.

Map of the Trinidad Coal Field in Southern Colorado

The Problem of Mine Timbering

By R. B. Woodworth*

The several forms of construction that are in common use for supporting mine openings and excavations, are discussed with regard to the character and magnitude of the stresses that they have to resist. The second of a series of articles on mine timbering with special reference to the use of steel.

Having reached the conclusion that the practice of timbering coal-mine excavations will necessarily be continued for some time to come, the question next arises what kind of timbering should be used in order to accomplish the most satisfactory results from the standpoint of scientific conservation of our resources by their right use. The consideration of this further question presents three main sides:

1. The technical side, which deals with the loads to be sustained in each type of mine timbering, their character and reactions, and the stresses they produce.
2. The physical side, which has to do with the materials of construction and their fitness for use in the various forms of mine timbering.
3. The economic side, which has to do with the costs of the materials, the relative value of the various forms in which they can be employed, and the question of whether, after all, the use of any particular material or any particular form of that material means ultimate economy in expenditure and the lowest possible maintenance charges. Ultimate economy in this connection must needs involve the humanitarian aspects of mining, the preservation of life as well as that of property—life insurance as well as fire insurance.

A full and careful consideration of all these phases is necessary in order to secure that greatly desired end, namely: the reduction of the cost of production to the lowest possible amount.

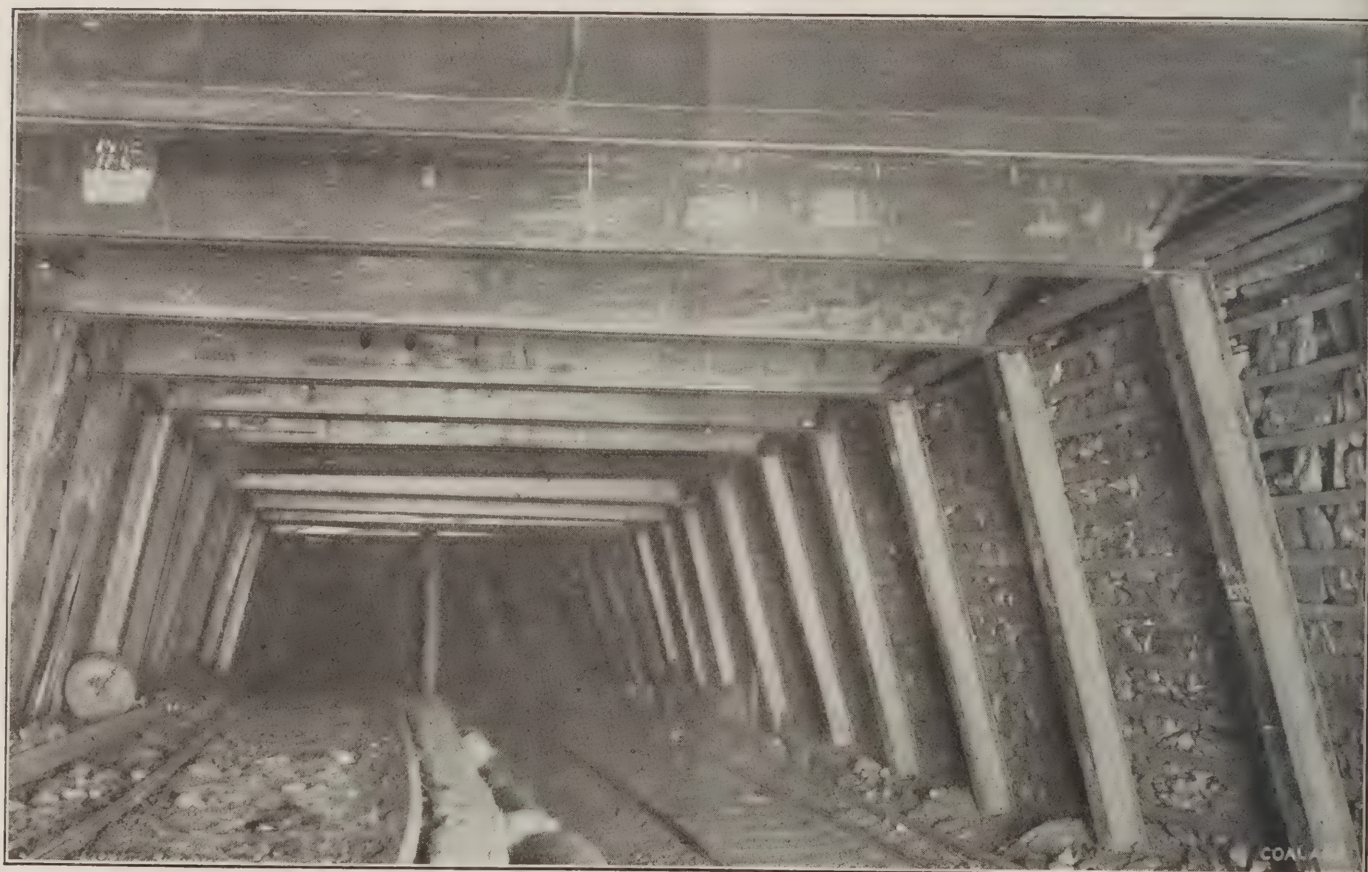
Note—Paper read before the Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.



Steel Timbering in Gangway, Maxwell Colliery, Wilkes-Barre, Penn.

Technical Aspects of Mine Timbering

The prevention of economic waste requires that the accepted practice in mine timbering be based upon correct principles of engineering design, which, in turn, requires accurate information as to the loads to be carried and the stresses induced thereby. This accurate information is not easy to obtain. There are no well defined rules by which may be calculated the load on a square mine-timber set, the compressive stress in a circular shaft lining or even the cross bending moment in a shaft compartment divider. Wooden mine timbers are installed largely on the basis of previous experience in their actual use either in the particular mine in which they are used or in some other mine subject to similar conditions. Even in the case of vertical shafts through undisturbed horizontal strata, the pressures to be sustained are dependent upon sinking conditions, a shaft through wet ground needing more material in its lining than one in the dry.

While the magnitudes of the stresses met with in mine timbering are problematical and do not admit of precise mathematical computation, their character and in consequence the proper form of sections to withstand them, can be understood from a study of the behavior under loading of the materials heretofore and at present used in underground construction. When, for example, a squeeze passes over a gangway timbered in the

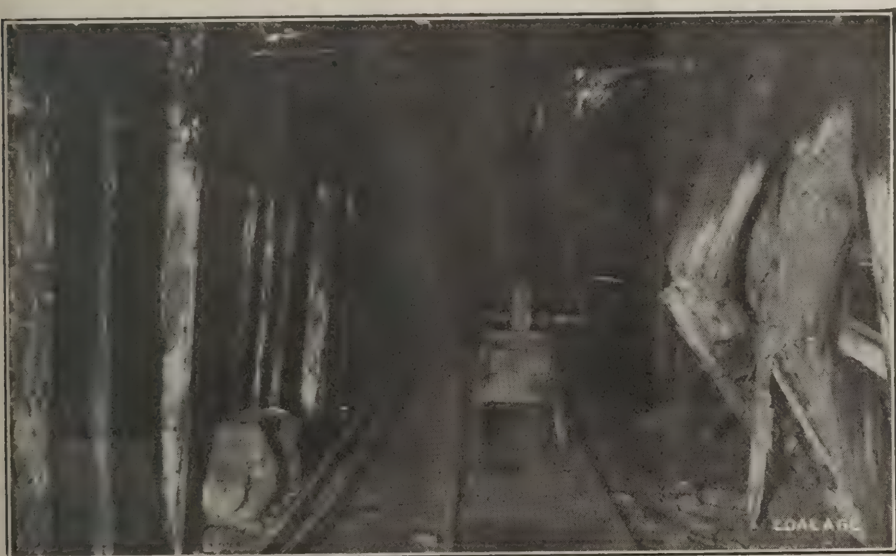
usual manner, the effect of its action is seen in the crushing-in of the collar by downward deflection and the breaking-off of the legs by bending in from each side towards the center line of the heading. The same thing occurs in an iron mine operated by the caving system, the tendency being always for the legs to break or shear off at about one-third their height, the pieces always falling toward the center of the excavation, while the collars fail either by breaking at the middle or by shearing at the ends.

In general, from the standpoint of engineering design, it does not make much difference whether the excavation is vertical or horizontal. The same general principles as to the character of the loading and the distribution of stresses apply in both cases. It is an interesting fact that the use of cast iron segments for lining subaqueous tunnels takes its rise from a previous use of identically the same thing in lining circular shafts. We may, therefore, argue with a high degree of certitude that what is true for the framing of a vertical shaft will also apply, in the main, to the framing of a tunnel or heading.

With these premises we may now proceed to examine into the various ordinary types of mine timber with a view to deciding what material is best fitted to replace wood wherever it is found.

Circular Shafts

The circular shaft lined with brick or cast iron segments is extremely common in England and Europe. All the fourteen shafts described by Meyer in his book on "Mining Methods in Europe" are circular except one, and that is elliptical. All the 150 shafts listed by J. Riemer in his book entitled "Shaft Sinking Under Difficult Conditions" are circular, except five. The circular shaft is hardly known in the United States. There is one in Grundy County, Illinois, and one in the iron region of Minnesota, but these two are all that I know of; and beyond doubt the usual shaft in the United States is rectangular. The advantages of the circular shaft (Redmayne, Modern Practice in Mining, Vol. 2) are: (1) Decreased cost of sinking due to the elimination of corners. (2) Smaller cost for lining. A rectangular shaft costs, in England, approximately $11.25 per ft. for timber lining whereas a circular shaft costs $6.00 per ft., when lined with brick at $5.00 per M. (3) Less difficulty in shutting off water than in a square shaft. (4) Uniformity of stress as regards position. The greatest width of a rectagular shaft should be across the cleat of the stone, so that the long side may be in the position most easily supported. (5) Decreased danger and expense as compared with a rectangular shaft, when passing through a fault. (6) Greater durability of cast iron and brick lining in the circular shaft as compared to the wood lining of a rectangular shaft.



Broken Timbers in Mine at Ironwood, Mich.

These advantages are due, in an ultimate analysis, to the mining conditions and to the geological characteristics of the strata through which the shafts are sunk and also to the materials used in their construction. In certain parts of England and in certain regions on the European Continent the upper strata are of recent geological formation, and the shafts are sunk in the valleys, while the seams of coal outcrop on the hills, sometimes many miles away. The result of this topographic configuration is to permit enormous quantities of water to percolate into and form reservoirs in the strata above the coal. As the shafts penetrate these strata, the pressures on the shaft lining increase approximately in the same ratio as the hydrostatic head. If under such conditions the shaft is made watertight, the shaft lining is in effect a tube loaded with a water pressure increasing in a constant ratio with downward progress, and, therefore, the thickness of the material of which it is composed may be determined by the rules that apply to hollow tubes. Of course, local conditions also may need to be taken into account, such as the inclination of the strata, the presence of faults and therewith the possibility of unequal rock pressures due to movement in the shaft wall, but in general, the tube formulas apply.

Rectangular Shafts

In the United States the coal-mine shafts are either not of any great depth, or where they are deep, almost always pass through strata of the Carboniferous Age. These strata are approximately horizontal in the bituminous coal regions or steeply inclined in the anthracite regions, in both cases extremely hard, free from faults and relatively free from water. The lining need not be watertight and is not, therefore, subject to hydrostatic pressure except in its upper sections. This condition, together with the relative cheapness of wood as compared with brick, etc., has made the rectangular shaft the standard practice in the United States, so that most shafts here are framed with wooden shaft sets and lagged with wooden sheathing.

The stresses to which rectangular shaft framing may be subjected, vary greatly with the character of the material through which the shaft passes. They may also vary with the verticality of the shaft, the members of an inclined shaft being subject to stresses different in character from those in the members of a vertical shaft. Shaft sets are as a rule placed normal to the axis of the shaft, and in a vertical shaft through solid ground and horizontal strata, the load to be borne will not be much greater than the weight of the lining.

The wall plates in such a shaft will, in general, be subject to bending stresses combined with direct compression, the loads inducing the bending stresses being applied transversely and the loads inducing direct compression being the end reactions from the next adjacent wall plates. The buntons or compartment dividers will take direct compression only, except for such small bending stresses as may be induced by their own weight or the weight of guides, ladders, pipes, etc. Where, however, a vertical shaft passes through inclined strata or an inclined shaft passes through horizontal or inclined strata, the buntons or compartment dividers may have to take, in addition to direct compression, bending stresses of large moment due to movement in the strata, while there will be

no sensible change in the character of the stresses in the wall plates. In a vertical shaft, the stuttles or hanging rods will take direct compression or direct tension only. In an inclined shaft they may be called upon to take, in addition, small amounts of cross bending stresses. We have thus in rectangular sets as ordinarily framed, all the varieties of stresses: tension, compression, cross bending and shear.

Elliptical Shafts

Rectangular cages are in almost universal use and the rectangular shaft, which is best adapted for framing in wood, offers also the largest useful area for a minimum amount of excavation. On the other hand, for the same area, useful or otherwise, the perimeter of the circular shaft is less than that of the rectangular. Given fixed sizes of cages, and ladder and pipe spaces, the useless area in a circular shaft may run from 25 to 45 % of the whole, and just that much additional expense for excavation, lining and maintenance must be offset by the cheapness of lining material and construction in order to make the circular shaft economical as compared with the rectangular form. The circular shaft has an advantage over the rectangular in that it offers less rubbing surface, and hence less friction to the air currents. The mining laws, however, usually require separate air shafts and this consideration is of little practical importance for main hoistways.

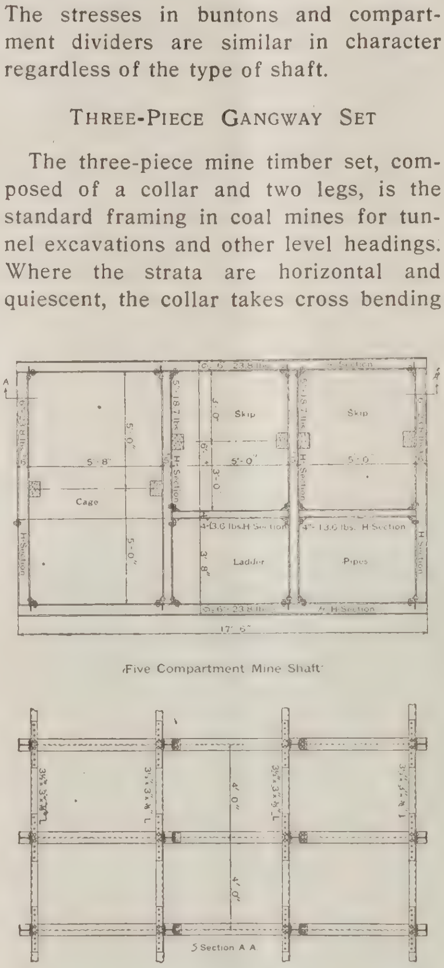
The elliptical shaft represents an endeavor to combine the uniform strength of the circular shaft with the space economy of the rectangular. It has not met with favor in England owing to the difficulties of keeping it plumb while sinking and the obstacles presented to the effective use of the standard walling or tubbing, the various sections of which must be special in the elliptical shaft while in the circular form they are alike and interchangeable.

There is some elimination of useless space in the elliptical shaft, so this type comes between the circular and the recangular in regard to the availability of space for mine uses. The elliptical shaft also takes advantage of arch action in the lining construction, which may, therefore, be of less thickness than if the shaft were rectangular. Where, however, the shaft is long and narrow, either the rise of the arch must be greater than desirable or else the lining must be made proportionately thick, with the danger of possibly giving rise to excessive shearing stresses between sections of different curvatures. The use of elliptical shafts in the United States is largely due to the employment of concrete as a lining material.

In rectangular shafts, the lining is simply a thin sheathing and serves only to hold the shaft from local fracture and to transmit local pressures to the frames which take all the important stresses. In circular and elliptical shafts the lining itself takes the stresses and, as ordinarily sunk, must be of constant or progressively increasing thickness throughout. The stresses in buntons and compartment dividers are similar in character regardless of the type of shaft.

Three-Piece Gangway Set

The three-piece mine timber set, composed of a collar and two legs, is the standard framing in coal mines for tunnel excavations and other level headings. Where the strata are horizontal and quiescent, the collar takes cross bending



Steel Framing for Five-compartment Shaft

stresses only and the legs pure compression. Failure takes place by the vertical deflection of the collar under stress beyond the elastic limit of the material or by the cross breaking of the legs under shear induced by undue compression. Where the strata are inclined and in motion, the collar may also have to take compression and the legs cross bending stress. In swelling ground, conditions are much the same except that instead of the sides of the excavation coming in, the bottom comes up or the top comes down, thus again throwing a bending stress into the legs. In case of failure, it is probable the pieces will fall towards the outside of the heading rather than towards the center. The character of the failure may be changed and its inception prevented, in a measure at least, by the use of mud sills under each set, which are always desirable in ground of this character.

Gangway sets in wood are usually made with all three pieces of the same diameter or width and depth. While in many instances this practice is wasteful, there are two reasons for it; first, the simplicity of the framing, and second, the low shearing value of wood and the possibility that under stress the full shear area may be required. As wooden mine-timber failures take place so largely by shearing, it would seem that after all, the practice may be in good accord with the best principles of structural design.

I have had occasion to coin the term "steel mine timbers" to cover the three-piece gangway set when framed in steel, and I use the term "roof support" to designate a single beam supported at its ends on the side walls and in turn supporting the roof. While the object of all mine timbering is to support the roof or hanging wall, the distinction between the framed set and the single piece has proven convenient. While it is conceivable in rare instances that they may have to resist compression, roof supports as a rule, whether of wood, steel or concrete, take cross bending stresses only, except at the ends, where they are subject to shear. They must, therefore, be figured by the formulas for flexure.

The Occurrence of Marsh Gas

By W. Hartman*

While marsh gas is occasionally found in the adjoining strata, it belongs essentially to the coal seams proper. Its distribution in the coal is often quite irregular. While not a positive rule, it is usually the case that the less cover over the coal, the smaller the quantities of gas found, since the light cover permits the gas to more readily escape.

As a result of a systematic comparison of a number of different coals, it has been found that those carrying from 20 to 25 per cent. volatile matter are as a rule the most gaseous. From coals of this volatile content, the gas proportion gradually decreases until it reaches its minimum in anthracite. This rule, however, should not be taken as infallible, for exceptions to it are not infrequent.

Thus, for example, a horizontal seam will often carry gas at one point and show no indications of it at others; and an outcropping seam seldom shows any gas near the crop but may have large quantities at greater depths. Probably one of the greatest influences on the gas contents of a fairly gaseous seam is the permeability of the strata that overlies the coal.

Use of Grout in Shaft Sinking

By R. C. Johnson*

One of the chief difficulties of shaft sinking lies in dealing with the water that is frequently encountered. Forcing cement grout into the fissures of water-bearing strata by means of compressed air is a new and effectual solution of this problem. The advantages of obtaining dry shafts are apparent to mine operators and include a great saving in the usual cost of pumping.

Without doubt the most important step that has been taken in connection with sinking shafts in this country during recent years, is the introduction of the process for cementing water-bearing seams encountered in the sinking. Although the process has been used in a rather similar form in Germany, no reports show that its practice has extended to the grouting of comparatively small water-bearing fissures, with the idea of making practically dry shafts. In general it has been used there only when huge flows have been encountered and exceptionally great expense for pumping has been forced on the operator.

The process as actually used here, is one of forcing Portland cement grout into holes drilled in the bottom of the shaft, the cement and water being mixed in an air-stirred grout tank which is connected directly to the compressed-air supply on one side and to the hole to be grouted on the other. In view of the wonderful possibilities that the process offers for saving money, a brief description of the method as it would be used in the sinking of mine shafts should be of interest to those who have shafts to sink or to those who for years have been pumping water from the bottoms of wet shafts. To the latter, the advantages of the process will probably appeal most strongly.

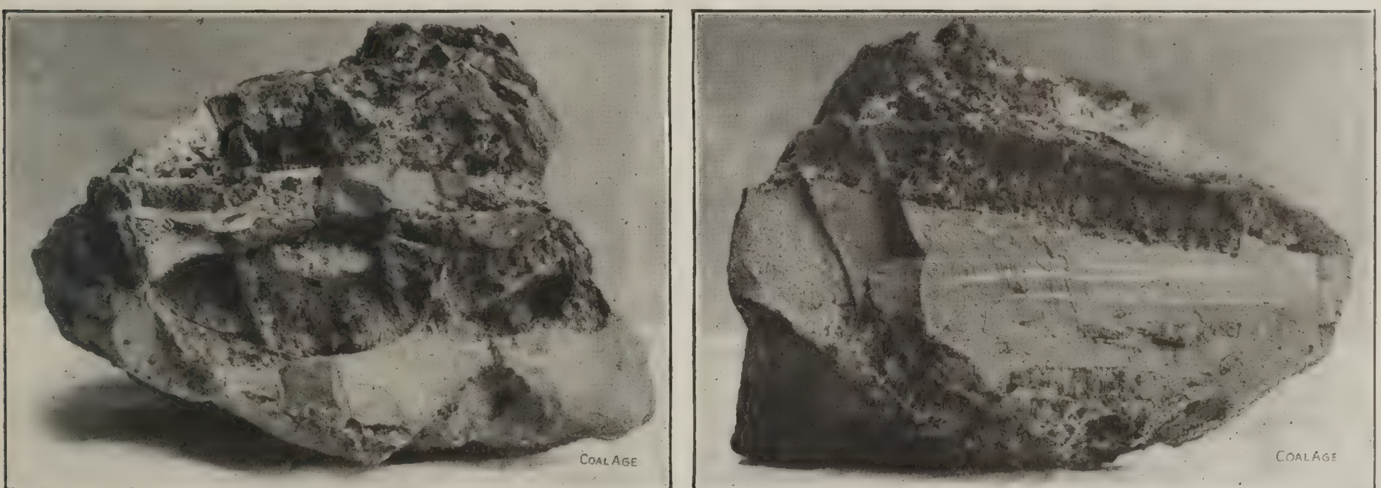

Fig. 1. Samples of Rock Showing Crevices Filled with Cement Grout

Description of Methods

Sinking is started in the usual manner. As soon as the drills "cut" water, preparations are made for grouting. The air line which is used for drilling is run close to the bottom of the shaft for connection to the grout tank. The drilling is continued until the longest length of steel used is run into the holes. Then the drills are taken out of the shaft and a small specially shaped pipe nipple, wrapped about its enlarged portion with flannel or burlap, is driven tightly into one of the holes.

To this nipple is connected a piece of high pressure hose that leads to the grout tank on the floor of the shaft. This tank is made of boiler plate, has about 4 cu.ft. capacity and is similar in shape to an upright air receiver on legs. As shown in Fig. 2, there are pipe connections for air at the top and bottom and a connection for the discharge of the grout. The sand, cement and water, which are admitted through a small opening at the top, are mixed into a grout by the stirring and bubbling effect of compressed air admitted at low pressure through the bottom inlet pipe. The only construction in the tank that aids the air in mixing the grout, is a steel grating placed midway between the top and bottom air connections.

At the bottom of the tank and opposite to the lower air connection is the pipe way for leading the grout to the drilled holes. The general arrangement is as shown in Fig. 3, certain additional blow-off pipes and connections for pressure gages being installed for cleaning and for testing purposes. Just before the grouting is started, the drill hole is cleaned by pumping, if it is merely a running hole; if the hole is a spouter it will practically clean itself.

Forcing in the Grout

The pipes are then connected to the nipple in the hole, the batch is put into the tank and air at low pressure is admitted through the bottom connection, for stirring purposes. Next, the tank door and all plug cocks are closed except one which admits air for running up the pressure in the tank to the desired mark. The plug cocks in the discharge line are then opened and the grout forced into the hole and into all the crevices leading to the hole. The holes are grouted to refusal, that is, until the gage shows by the rise of pressure that all crevices connecting with the hole are filled. The plug cock nearest the tank is then opened and the charge wasted. The other plug cock, immediately above the hole, is next closed, the grout hose disconnected from above the valve and the tank and pipes cleaned by blowing out.

The apparatus is then connected to another hole. If the grout from the first hole is seen bubbling up in other holes, they are immediately plugged. Such bubbling shows, of course, that fissures are connecting the several holes. The one grouting connection will in this case serve for all the holes in which the grout is seen. If the grout is seen to rise through crevices in the floor of the shaft, a different method of procedure is required. It is necessary to place over the

*Engineer with the Dravo Contracting Co., Pittsburg, Penn.

floor of the shaft a reinforced concrete mattress which is allowed to set for a couple of days. Holes are then drilled through this mattress, just as if it were a shaft bottom, and the grouting process continued as before.

At first, the drill holes are spaced over the shaft bottom just as they are spaced for shooting and the grout tank is connected to every hole that shows water. The grout is allowed to set for about 8 hours and after this, test holes, deeper than the regular round, are

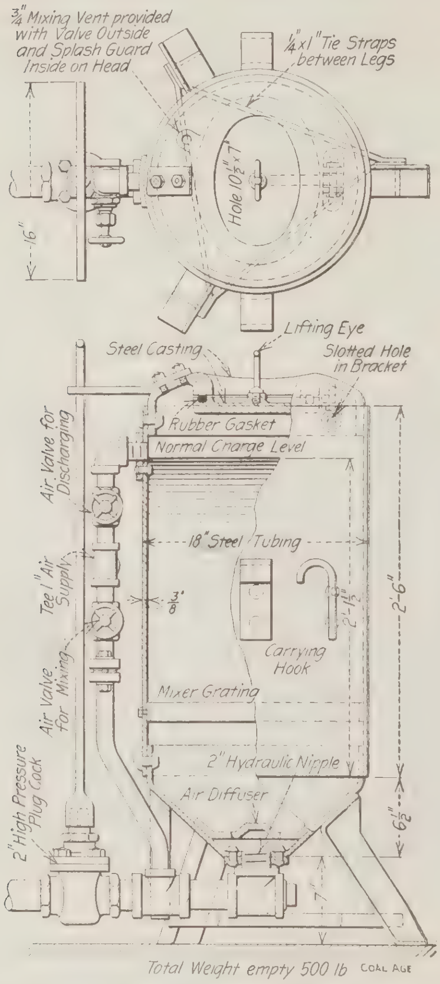

Fig. 2. Grout Mixing Tank and Connections

placed along the rib. If these show water, they are grouted and additional test holes are drilled until no water rises from the rock. The shaft is then again drilled for shooting, the number of side holes being increased so as to cut the rib as clean as possible and keep the grouted seams solid. In the regular process of sinking the shaft, the sump is then fired and mucked. The grout will appear in the crevices it has filled, like a white fine-grained sand stone. In one instance, a section of a gneiss rib, so treated, appeared as a prominently white-streaked dark marble. The benches are then fired and sinking resumed in the usual manner until more water is "cut," when the process is repeated.

Pressures Required for Grouting

The pressure required to grout a hole is dependent on the pressure of the water coming from the hole because the grout must take the place of the water. Theoretically the application of this process is limited only by the pressure that the air compressor can develop and the air connections can withstand. The height that the water reaches as it spouts from the drilled hole is an accurate indicator of the least air pressure that will be required but the pressure actually used will be often much greater than indicated by this head, in order that the most minute crevices may be plugged.

However, when using high pressure every precaution must be taken against blowing out the nipples and breaking the connections. In one case, described later, it was actually necessary to drill the rock and insert wedge bolts to chain down the pipe connections to the holes. The water and sand spouted from these holes with such force that a 2" plank, placed over the hole to deflect the water, was in one case completely bored

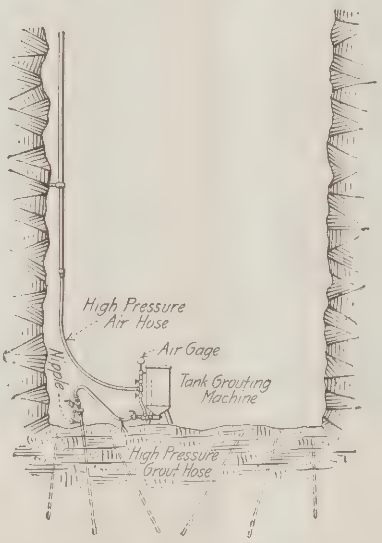

Fig. 3. Shaft Bottom, Showing Arrangement of Grouting Device

through in about two minutes. While drilling one of these holes, a 10-ft. steel dropped down the bore when it struck a stratum of sandy disintegrated gneiss that was later found to be producing the water. In a few minutes the steel was seen to shoot out of the hole and some distance up the shaft with a stream of sand and water behind it.

Recent Grouting Operations

In sinking the No. 4 shaft of the city tunnel for the Catskill Aqueduct in New York, a stream of water was encountered at a depth of 149 ft. As soon as the drills struck the water the contractor decided to attempt to cut off the flow by plugging the crevices with cement grout. Anyone familiar with shaft sinking knows of the many difficulties of pumping, and in round shafts such as are the large majority on this Aqueduct, the troubles are more than doubled because of the general practice of drilling the entire round on one shift. The handling of a pump at the bottom of a round shaft for only 30 gal. of water per min. means a loss of at least 5 ft. of sinking per week. It was of advantage then, both to the city which paid for the pumping and to the contractor as an aid to his speed that the water bearing fissures should be grouted if possible. Accordingly a grout machine of the Caniff patent type was procured and taken down the shaft for connection to the holes showing water. Only two days were lost in completely sealing off the flow and the sinking was resumed.

However, on Oct. 28, at a depth of 183 ft., the drills "cut" a stream of such high pressure that while there was no loss of time in deciding what methods to pursue, there was, and still is, considerable speculation as to its cause. A gage placed on one of the drill holes regis-

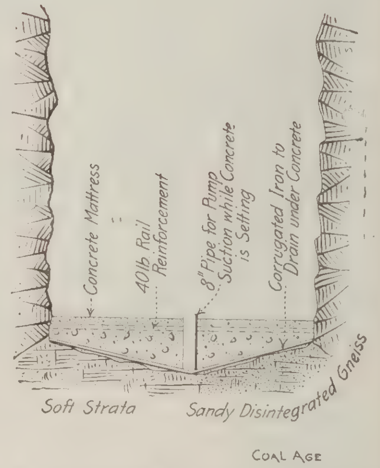

Fig. 4. Concrete Mattress at Bottom of Shaft

tered 65 lb. and it required but a moment to figure that the water was coming from near the rock surface. The shaft is situated within 100 ft. of the Jerome Park reservoir and within a few hundred feet of the Croton Aqueduct. Shooting into the water under such pressure seemed suicide and as later developed, the shaft would probably have been "drowned out" had it been attempted.

It was decided to provide a high pressure grout machine with high pressure fittings. As previously noted it is essential that the grout be forced into even the finest crevices, and when it is known that over 300 lb. pressure was used on some of the holes—335 lb. on one of

them—the effectiveness of the work can be appreciated. Nevertheless test hole after test hole was drilled and still the water persisted in appearing. Finally a complete ring of holes was drilled around the periphery of the shaft, the holes being kept close together. These were grouted and the cut and side holes fired. The water pressure had decreased considerably but a new condition appeared.

A Concrete Mattress Used

The bottom of the sump was soft and sandy and soon proved to be badly disintegrated gneiss, an unusual occurrence, surrounded as it was by the hardest kind of material. Attempts to grout off the water in this sandy structure failed at first because the grout would bubble to the surface and allow but little pressure to be put into the holes. It was finally found necessary to cover the whole shaft bottom with a reinforced

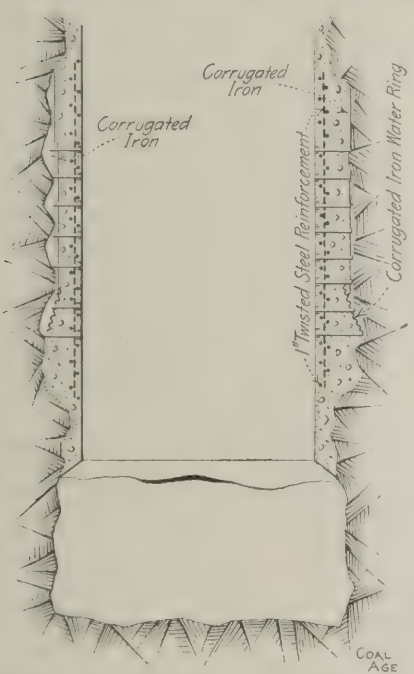

Fig. 5. Reinforced-concrete Shaft Lining

concrete mattress as shown in Fig. 4. The concrete was placed on corrugated iron to allow drainage to an 8 in. pipe that was stood upright in the center of the shaft to carry the pump suction while the concrete was setting. Holes were then drilled through the mattress and down into the rock and attempts made to grout.

The flow was decreased considerably but not entirely. The reason for this became clear when the concrete was removed and the rock shot up. Pieces of the grout, shaped precisely like a diamond drill core, were found in the muck with clumps of cemented sand clinging to them. Clean, or even fairly clean, crevices were grouted perfectly but strata of sand were only matted in spots and it was from these strata that the remaining water was coming. Sinking was then continued for about 20 ft. and the regular concrete lining of the shaft was started.

The shaft was enlarged through the soft sandy strata so as to permit ample drainage channels behind a heavier-than-usual reinforced concrete lining. As reference to Fig. 5 will show, grout pipes were run from the inside face of the lining back to these drainage channels. These pipes carried the water through the lining into the shaft and after the concrete had set for a week or so, they were closed with ordinary plugs, thus completely shutting off the entire flow. Later, these plugs were removed and grout forced in behind the lining to fill the drainage channels.

Advantages to the Mine Operator in Obtaining Dry Shafts

The fact that the problem of dealing with the water encountered in sinking a shaft has met with a new and effectual solution, marks a big step forward but by all odds the greatest advantage of the grouting process is the saving of money that the mine owner would otherwise have to spend year after year in pumping the water of a wet shaft. The cost of pumping 200 gal. of water an hour from the bottom of a mine shaft 500 ft. deep is easily figured. This is probably an average quantity for a shaft of that depth and will require about 25 water horsepower. Taking as a basis a direct acting pump using 90 lbs. of steam per horsepower hour it is readily figured that 75 boiler horsepower are required. A horsepower will cost the mine operator about $20.00 per year and $1500.00 per year will be the total expense for pumping the shaft water.

Grouting with cement and sand as the shaft is being sunk will save this expense and under ordinary conditions, crevices that will produce a flow of 200 gal. per hour, can be grouted solid for much less than a year's cost for pumping. With successful grouting, no water rings will be required and so the actual increase of first cost to the mine operator will be small. The idea is new in this country and the method as it has been described here is entirely new to shaft sinking practice. It has proved a success in every instance that it has been tried of late and engineers who have studied the operation pronounce the shaft water problem solved.

In certain English mines, experience has shown that a small quantity of soap dissolved in mine-sprinkling water adds to its effectiveness as a dust layer, as the soap tends to coagulate the dust and hold it down.

Pittston District Mining Institute

Special Correspondence

The annual dinner of the Pittston District Mining Institute was held, this year, in the new State Armory, at Pittston, Penn., Saturday evening, Feb. 17. The banquet was the most successful that has ever been conducted by the Institute. It was attended by 600 of the seven or eight hundred members. W. T. Jennings, superintendent of the South Pittston district, for the Pennsylvania Coal Co., and president of the institute, presided with his usual grace and efficiency. President Jennings introduced, as the toastmaster of the evening, Judge O'Boyle. The judge delivered a well rounded and eloquent address, and told in his own inimitable fashion many amusing stories.

One of the best and most forcible addresses of the evening was made by the Rev. W. T. Blair, of Plymouth, Penn. The reverend gentleman's subject was, "The Man on the Job." The address was full of encouragement and inspiration.

An excellent address was delivered by Samuel J. Jennings, mine inspector, eighth anthracite district, outlining the work and the purposes of the Miners' Institute. Mr. Jennings asked for a greater interest and coöperation on the part of all the members, and hoped in the coming year that they would be able to reach a larger number of the foreign element among the miners, and be able to help them to a better understanding of mining dangers and conditions.

Other District Institutes Send Greetings

The greetings of the Scranton District Mining Institute were presented cordially by Mr. Andrew Bryden, of Scranton. Mr. Charles Enzian, of the Bureau of Mines rescue work, was present, bringing the greetings of the Wilkes-Barre District Institute. Hon. James E. Roderick, chief of the department of mines, Harrisburg, Penn., was to have addressed the meeting, but was unavoidably detained.

The final address of the evening was given by J. T. Beard, associate editor, Coal Age, New York City. Mr. Beard spoke briefly of the peculiar environment of the coal-mining industry at the present time. He referred to the fact that coal, being a necessity of life, its price was limited to what may be called a *living price*. This was stated to be the upper limit, while the *living wage* demanded by the miner was described as the lower limit in the cost of production, in coal mining. Mr. Beard drew the conclusion that the range between these two limits was so narrow as to require a greater efficiency on the part of mine officials and miners alike. This was declared to be the practical solution of the problem.

Rock Dust in Explosions

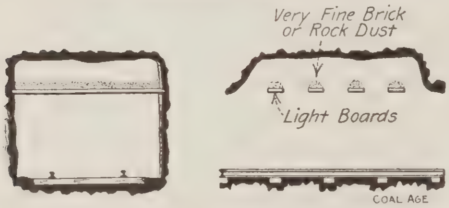
By A. E. Lindrooth*

The many recent disastrous mine explosions have shown one thing conclusively, and that is that could each explosion have been limited to the entry in which it started, the loss of life and damage to the mine would have been small.

There is a need for a simple and reliable method of stopping the progress of the flames propagated by the explosion.

From England comes a hint that is at least worth while trying. The flame of an explosion is doubtless of exceedingly short duration, and if a dead space of 20 or 30 ft. could be provided at each entry, it is probable that most of the explosions would be limited to the entry in which they originate.

The suggestion is to provide a means of instantaneously filling a portion of the entry with a noncombustible powder which will dampen the coal dust and stop the progress of the flames. This is accomplished by taking down about 2 ft. of the roof and resting light boards



Rock Dust for Deadening Explosions

about 10 in. wide, spaced about 22-in. centers, on notches made in the opposing ribs, and covering the boards as thickly as possible with exceedingly fine or impalpable rock dust. The force of an explosion would tend to dislodge this dust in a large volume, thus completely clouding the air and forming an obstacle to the spread of the flames. The scheme is so simple and so easy to try that further experiments should be made to determine its efficiency.

Electrical Shot Firing

By W. Hartman†

The principal disadvantage of electrical shot firing lies in its lack of simplicity, since electric current, wires and special detonators have to be arranged for. For this reason this method is often rather expensive.

As far as the safety of the miner is concerned, electrical firing is much superior to other methods, as it gives the greatest assurance that the shot will go off at a fixed time; thus enabling the miners to go to a safe place and fire the shot at their leisure. It also eliminates the danger incident to going back on a dead shot—a frequent cause of serious accidents. In addition to this, the gaseous condition of the mine need not interfere with the shooting.

In firing all the shots in the entire mine simultaneously, the danger of a dust explosion is also eliminated, or greatly reduced, as conditions at the face remain the same for all shots. On the other hand, when fired with fuse, by the time the last shots are being fired, the mine air is so agitated and filled with flying dust as to be in a highly dangerous condition.

The simultaneous discharge of a number of shots at the same point is also of advantage from an economical standpoint, as, when shooting off the solid, the result of several shots fired at the same instant is nearly double that when fired separately.

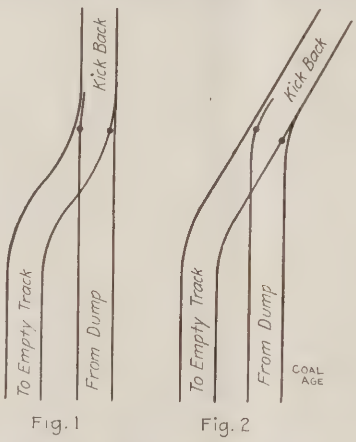
Cross Over Dumps

By Benedict Shubart*

Where cross-over dumps are used, the ordinary straight track kick-back is a source of constant delay, due to derailed cars, particularly where cars have a short wheel base or are old and rickety.



Wrong and Right Way to Install a Kick-back

The usual method of laying the kick-back track is shown in Fig. 1. By laying the track as shown in Fig. 2, the switch is passed while the car is going comparatively slowly. Furthermore, the switch is trailing. When the car returns from the kick-back, it runs on the straight track and is much less liable to derailment. The curves shown on the sketches are exaggerated in order to convey the idea. In fact, the curves should be as long as the limits of the tipple will reasonably permit.

The coal fields of Spain cover an area of 4117 square miles and give employment to 26,932 persons, 1128 of whom are females. Anthracite, bituminous and lignite are included in the production.

*Boston Building, Denver, Colo.

Fifteenth Annual Banquet of the Northeastern Pennsylvania Engineers

Special Correspondence

Nearly 300 men attended the 15th annual banquet of the Engineers' Society of Northeastern Pennsylvania, held at the Hotel Casey, Thursday evening, Feb. 15. The whole affair was both interesting and instructive—interesting, because of the good cuisine service, and the excellent music rendered by a local quartette; instructive, because of several worthy addresses.

The president's address, delivered by A. B. Jessup, mining engineer of the Lehigh Valley Coal Co., was a most excellent talk, one of the very best it has been our pleasure to hear this gentleman deliver. Mr. Jessup particularly boosted the idea of a club house for the members of the society, and it does seem that such a representative body of engineers, largely concentrated in a small area with first-class transportation facilities, should be able to supply themselves with a common meeting place in keeping with the great industry these men represent.

Homer Greene, of Honesdale, Penn., was toastmaster and performed this service in a most creditable manner. Mr. M. W. Alexander, of Lynn, Mass., gave a talk on "The Industrial Value of Engineering Education." Mr. Alexander handled a rather dry subject in such a way as to command the close attention of those present. His experience derived from his sociological work with the General Electric Co. fitted him admirably to present interesting thoughts on present industrial problems.

Mr. Bigelow, state highway commissioner of Pennsylvania, talked to the engineers present about "The Roads of Pennsylvania and What the State Expects to Do with Them." Other addresses were delivered by Judge Newcomb, of Scranton, and Mason D. Pratt, president of the Engineering Societies of Pennsylvania, Harrisburg, Penn. Mr. Pratt advanced the suggestion that it would be a good thing for all the engineering societies of Pennsylvania to unite in a great federation so as to increase their power and thereby enlarge their influence for good.

The points which most impress mining experts visiting foreign coal mines are: In England, the care given to underground details and the perfection of all construction work; in Belgium, the high degree to which hospital and rescue work have been carried; in Germany, the magnificent equipment of the mining plants and power houses, and the fight against ankylostomiasis, carried on by means of sanitary provisions underground and baths for the miners; in France, the completeness of chemical, electrical and laboratory research.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Causes of Gob Fires

The report of W. H. Pickering, of the York and North Midland inspection district of England, gives the following details relative to the danger of explosions resulting from gob fires, and the causes which aid and create the latter: "When stoppings are being erected to shut off a gob fire, there is always serious danger of an explosion in cases where inflammable gases escape from the strata or are distilled by the heat. The danger increases with the extent of open area inclosed. If there are large open spaces beyond the stoppings, the danger of a violent explosion is great; but if the open area inclosed is small, an explosion is unlikely, and if one occurs it will be in the nature of a puff of flame with little force.

The danger is far greater shortly after the air current has been stopped or checked by the building of walls. The spaces within the stopping will be unventilated, and explosive mixtures of gas are likely to accumulate. The air will not be stagnant, for the heat of the fire will produce currents by convection, and these may be the means of carrying the explosive mixture to the fire. If no explosion occurs shortly after the air current is cut off, the danger is usually over, for the supply of oxygen will rapidly diminish and the products of combustion will also make the formation of an explosive mixture impossible. I had the experience of witnessing a very violent and extensive explosion while a colliery fire was being sealed. It occurred about five minutes after the air current was cut off.

Why Gob Fires Occur

The danger of gob fires is greater in the newer pits, for up to the present the fires have been more numerous, and extraordinary quantities of firedamp are found. In some cases petroleum oil drips from the roof, and saturates the timber. This is another element of danger. The gob fires occur for the most part at the edge of the shaft pillars, and in places where ribs or pillars of coal have been left or lost, and where timber has been left in the gob. Fires occasionally occur in the roadways in the coal, and at times in the shale over the seam.

At first sight it might be assumed that the fires in the Yorkshire mines were the result of leaving so large a percentage of coal in the gob. No doubt, this makes fires more serious and dangerous when they occur, but it is by no means certain that it is the primary cause. If it were, then fires could not fail to be more numerous at the pits where coal equal to a seam 4 ft. thick is left to be ground to slack in the gob.

At some of the collieries no fires occur, though their neighbors, working the same seam under what appeared to be the same conditions, have serious trouble. There is some evidence that the fires usually have their origin in breaks in the hard or steam coal, and they seldom occur when the whole of this is extracted. As this is the most valuable part of the seam, it is not left except in cases of shaft pillars, heavy falls, faults, etc.

Practical tests seem to show that this coal is more difficult to ignite than the soft coal, and it is posible that the fires are caused by the fine dust which results from the grinding of the soft top coal during the settlement of the strata. This lodges in the cracks of the hard coal and rapidly absorbs oxygen. This coal also contains iron pyrites, which would generate heat in such circumstances if moisture were present. Timber is far more easily ignited than coal, and that is the reason why it is dangerous to leave it in the goaf; it does not cause the heating, but supplies the tinder.

Periods of Danger

I am indebted to Mr. W. H. Chambers for a list of gob fires at Denaby and Cadeby Main Collieries during the past 30 years. Perhaps there may be some atmospheric reason why so many of them have occurred during the months of November and February. The figures for the months in which gob fires started are: January, 2; February, 8; March, 5; April, 1; May, 6; June, 3; July, 4; August, 6; September, 3; October, 4; November, 10; December, 4—making a total of 56, or nearly two a year. At the two new collieries recently opened in the Doncaster area, 17 cases of spontaneous combustion were reported during the past year."

Conveyors for Use at Coal Face

By H. Ridsdale

Several types of conveyors are being used in England to convey coal from the shoveler to the car. Some are continuous, some discontinuous and reciprocating. They not only increase output but reduce risk from falls of roof.

Note—Abstract of paper read before South Staffordshire and Warwickshire Institute of Mining Engineers, England.

The use of coal-cutters necessarily concentrates longwall workings, and, in order that they may be a commercial success, it is necessary to clear away rapidly the machine-cut coal from the face. This can be done either by an increased number of roads, or by the use of conveyors; and it is because the maintenance of roads—especially in thin seams—is such an expensive item that conveyors have been designed. Nearly all types of conveyors in use at the present day have been specially designed to suit some particular local conditions.

Apart from giving rapid clearance to coal-cutters, conveyors reduce labor and deadwork charges, even when coal-cutters are not employed. These charges are not only reduced by the rapid working of the seam, thus securing an increased output from a given length of face, but also by the consequent reduction in the ripping and deadwork required in the face and roads. The reduction of labor-costs naturally raises the question of the method of payment for labor in connection with conveyors. Various methods have been tried, and perhaps the most successful is the division of the tonnage delivered by the conveyor in proportion to the number of cubic yards worked by each individual man. Other methods have been adopted, such as payment of day wages, but everyone knows the disadvantages of this method; while, in other cases, the conveyor face has been let to a contractor; but, since he is a man without capital, the employer is usually expected to make good his wages in case of a deficit, while in the alternative the contractor reaps the benefit.

Electricity Economical but Compressed Air Safer

Conveyors are usually driven either by electricity or by compressed air; the former method is probably the more economical, while the latter is probably the safer, more particularly if the engine be placed at the delivery end of the conveyor. There a cloud of dust is created, which suggests the necessity for brisk ventilation, and seems to point to the use of compressed air. The position of the motive power for driving conveyors is usually fixed by the makers, but in some instances this is left to the discretion of the user. There are two positions available; the one at the delivery end, where it is under the direct supervision of the filler, and therefore to be preferred; the other at the trailing end, where it renders the tension arrangements simpler.

The Blackett Conveyor

The Blackett conveyor, which consists of an endless chain working in steel troughs supported by an angle-iron frame built up of sections called "gates," which are joined together by short spikes fitting into circular holes. The fact that the chain is made up of links, any one of which can be opened, and as many links as desired inserted, allows of an easy lengthening of the chain or the replacement of a broken link (unless it should happen to be in the bottom chain), and this constitutes one of the chief advantages of the conveyor.

The motive power, speed-reduction gear, sprocket drum and end trough are all mounted on the same bedplate, and

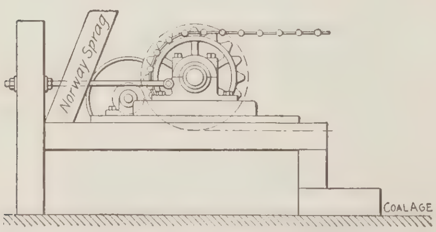


Fig. 1. Tension End, Blackett Conveyor

the whole can be swung across with a Sylvester pulling bar, when moving the conveyor forward. At the tension end of the conveyor the gates are held in position by two sprags placed between the roof and the bedplate, and the chain is tightened by the nut and bolt arrangement shown in fig. 1.

For the proper working of this conveyor, it is absolutely essential that it be laid down in a straight line, and that the floor be even. With an uneven floor, or in case of incorrect alignment, the chain will rise in the troughs. The chain tends to pull straight and in moving round a curve, under heavy load, it rises from the bottom of the troughs, allowing some coal to get underneath and forcing humps over the sides. Slack is also a source of trouble, as the chain will ride on it.

The Sutcliffe Conveyor

The Sutcliffe conveyor is similar in design to the Blackett conveyor, the chain being replaced by an endless canvas or wire-cloth belt 20-in. wide, which runs between two 3 by 3-in. angle irons supported on brackets. These angle irons are made in 9 ft. lengths, and are fixed to the brackets by bolts so as to form a

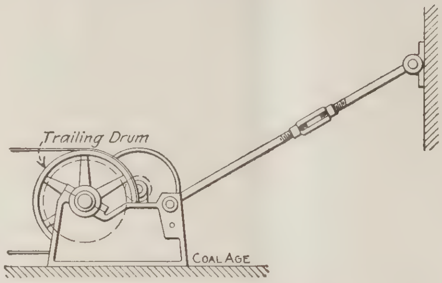

Fig. 2. Tension Arrangement, Sutclifee Conveyor

trough; the brackets are 9½ in. wide at the top and 13½ in. at the bottom, and stand 13½ in. high. Each bracket supports two rollers, one to carry the top and one the bottom belt; intermediate rollers are also placed halfway between the brackets for the top belt to run on, these rollers being fixed to the angle irons. The belt is joined together by riveting copper plates on to each half of it, so forming a dovetail joint like a hinge, through which is passed a steel or copper pin.

It is not desirable to have too many joints on the belt, or to have these too close together, as, being less flexible than the belt itself, they become a source of trouble. The engine, driving gear and first pair of angle irons are in this case mounted on one bedplate. The engine is slightly larger than in the case of the Blackett conveyor and drives the belt by a chain and sprocket wheels, the larger sprocket being attached to the drums round which the conveyor belt passes.

The belt in returning is carried over a roller fixed immediately behind and geared with the drum, so that the belt is in contact with at least two-thirds of the drum surface. The engine is capable of driving a conveyor up to 150 yd. in length. This conveyor is made so that it can be reversed when desired. The tension on the belt is obtained by using a Sylvester pulling bar or chain block the final adjustment being made by a double-threaded screw, as shown in Fig. 2.

The conveyor is moved toward the face in almost precisely the same manner as the Blackett conveyor, and, if the roof will not permit of its being swung bodily across, it must be systematically taken to pieces. It has been found in practice more convenient and better for the working of the conveyor to avoid breaking the same joints each time when moving it. This machine has one advantage over the Blackett conveyor; it will carry slack and small coal without difficulty; on the other hand, water will cause the belt to slip on the drum.

The Ritchie Conveyor

The Ritchie conveyor consists of a canvas-wire belt about 25 yd. long, working to and fro in steel troughs by a main-and-tail haulage arrangement, the main rope being attached to the front end and the tail rope to the back end of the belt. The troughs are made in 6 ft. lengths, 22 in. wide, 8 in. deep on the gob side, and 4 in. deep on the face side, to facilitate the filling of large coal. In order to prevent the belt from catching in the ends of the troughs as it travels backwards and forwards, projecting edges are avoided by specially constructed overlapping curved joints, made as shown in Fig. 3.

The engine (which may be similar to that used on the Blackett conveyor), speed-reduction gear, and main-and-tail drums, are all supported on angle-iron framework, and the whole run on rails in the gate-road, thus rendering all working parts easily accessible. The drums are driven by a chain drive and gearing, and are thrown in and out of gear by means of friction clutches. The first trough, which is fixed to the angle iron framework by four bolts, is placed immediately over the main drum, and projects beyond

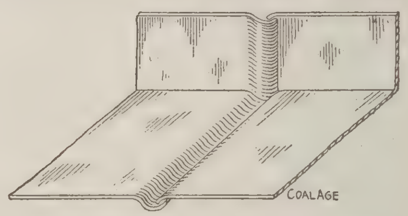

Fig. 3. Trough Joints of Ritchie Conveyor

it, allowing the belt to be wound on the main drum as the coal falls into the car.

This conveyor has the advantage of being easily and rapidly moved, even though it has to be taken to pieces. This type of conveyor is more simple to lengthen than the Blackett, and an undulating floor is not detrimental to its economical working. It has also these further advantages—no tension is required, and it takes an even load in either direction. It has, however, one advantage—it necessitates driving a road sufficiently wide to carry both the engine and the car to be filled. I again find it extremely necessary to insist that this conveyor must work in an absolutely straight line, otherwise the belt will catch in the troughs and buckle up.

The Gibb Conveyor.

The Gibb conveyor, which consists of two end-discharging gears and several intermediate cars, the number of which depends entirely on the length of face and local conditions, is a type of conveyor in which the position of the engine is not necessarily fixed, but the best position for it is at the delivery road. In order that the car may be efficiently filled the buffer skids must project out to about the middle of the road, and this projection is awkward and inconvenient. This conveyor need rarely be taken to pieces when being moved.

A soft and undulating floor is very detrimental to the economical working of this conveyor, and if these conditions prevail trouble is bound to arise. The conveyor must also work in a straight line; it is advisable to keep it a reasonable distance from the timber, as loose coal or rock will at times cause it to turn over and knock out the props. The efficiency of the conveyor depends on its being rapidly filled and emptied; and, consequently, if the coal requires much manual labor to get, the work is better concentrated on a length of face about equivalent to that of the conveyor, usually from 45 ft. to 75 ft.

Fig. 4.

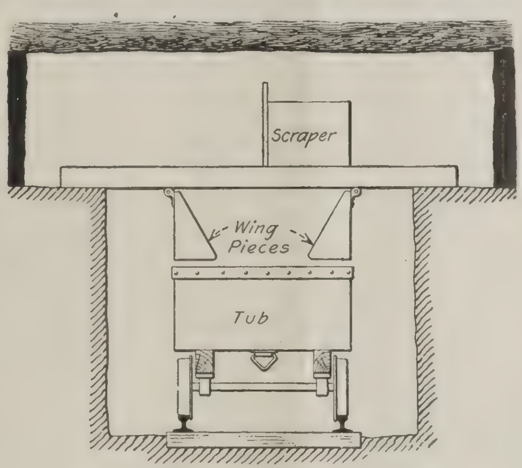

Fig. 5. COAL AGE

Figs 4 and 5 Show Section and Loading Arrangement of Thomson Conveyor

The Thomson Conveyor

The Thomson conveyor may be described as a broad iron trough having one side removed, built up in sections, each section being 6 ft. long, 21 in. wide, and 8 in. deep on the gob side, the face side being the one left open to facilitate the filling of the conveyor (Fig. 4). The sections are joined one to the other by a shackle and pin, the joints being protected by the sections overlapping each other. Riveted to each section are two strong steel skids, on which the conveyor slides along the floor. As the sections stand 4 in. off the ground, the extreme total height of the conveyor is 1 ft., and it can therefore be used in a thinner seam than any other type, which is one of its advantages.

The conveyor is designed to work in a face twice its own length, the delivery road being fixed in the middle. The conveyor works across the road on a bridge constructed of two steel girders spanning the opening; and to this bridge are fixed one or two scrapers, according as the delivery road is single or double. The scraper is hinged at one end, the hinge being bolted to the bridge, and is prevented from swinging too far in either direction by two pins.

The working of the scraper is automatic, the conveyor pushing it until it attains an angle of 135 degs. to the direction of motion, so that, as the conveyor passes on, the coal is diverted into the car beneath. Two wing-pieces placed underneath the bridge form a chute into the car. Fig. 5 is a sketch of the bridge. It must be noted that these wing-pieces constitute one disadvantage of the conveyor, in so far as they necessitate more being cut out of the road bottom.

I would advise a double road being used, in which case the two scrapers work as already described, one scraper being put out of action as circumstances require by lifting out the pin and swinging it back. The advantage of having the double road is that no time is lost in waiting for a car; but at the same time it must be remembered that a double road is being driven to serve one conveyor only, and not two, as is the case with the Blackett conveyor, for instance.

The makers use only one rope to drive this conveyor, but experience goes to show that it is better to use two ropes working on the main-and-tail haulage principle, which does away with the tension arrangement. If this method be adopted, it is found in practice advisable to have the conveyor working on one side of the timber and the rope on the other. The engine is usually fixed in a recess a little distance along the face. Any type of engine may be used, the horse-power depending entirely on the length of face to be cleared.

This conveyor is easy to move; it is simply drawn up to one end of the face, the main rope is then disconnected, taken round the timber, up the new run, and connected up again. A few props are knocked out near the bridge and the conveyor bodily pulled across into its new position, being guided through the pathway made by knocking out the timber. The last section of trough generally has to be moved by hand. When the conveyor has been completely pulled over, the tail rope is disconnected, taken round the timber, up the new run, and connected up again; the pulleys at the two ends of the face are moved, care being taken to get them into their correct position, as the satisfactory working of the conveyor depends largely on this. Lastly, the bridge is moved into its new position, its correct alignment, which is an important point, usually being determined by the lie of the ropes. This conveyor, like all others, must work in a straight line, but an undulating floor is not so detrimental to its economical working as in other types.

The Bunker Conveyor

The bunker conveyor is the cheapest and simplest of all the conveyors; it consists essentially of trams, the size and number of which depend entirely on local conditions. In the conveyors of this type which the writer has seen, the trams were made of sheet iron, with all four sides sloping at an angle of about 30 degs. towards the bottom. The dimensions of the bottom of the tram are 3 by 2½ ft., and the depth on the gob side 18 in., the face side being again lower to facilitate the filling of large coal. The bottom, which is the great feature of this conveyor, consists of two doors hinged at the ends, opening outwards and downwards and normally kept shut by means of a bar and pin, as shown in fig. 6. Fig. 7 shows a side elevation of a tram with the doors open. The trams are connected together by a shackle or coupler and run on rails which bridge the delivery road in a manner similar to the Thomson conveyor. It is the usual practice to make the gauge the same as that of the pit cars, although this rule need not be adhered to.

The engine driving this conveyor is situated in a recess in the gob near the delivery point, and the driving rope passes from the front end of the trams around a pulley at the top end of the face, back on to the driving wheel of the engine, whence it passes round a pulley at the other end of the face, finally finishing up on the back of the trams. The method of driving may thus

be compared to endless haulage. The necessary tension on the rope is obtained by means of a Sylvester pulling bar attached to one of the pulleys at the end of the face.

Almost any type of engine can be used for driving the conveyor, but a totally enclosed engine is to be preferred. The method of filling with this type of conveyor is as follows:—The car is brought up under the bridge, the first tram of the conveyor brought over it and the doors opened, thus allowing the coal to fall into the car, when empty, the doors are shut; the next tram is brought into position, and the process is repeated until the car is full. One of the chief advantages of this conveyor is that it will operate almost any length of face; but it is the better practice to have the delivery road in the middle of the step being worked.

The conveyor is moved in the following manner:—The trams are first drawn up to one end cf the conveyor face, the tension is slackened, the rope uncoupled and coiled up, and the rails are moved and relaid in their new position until the trams are reached. The trams are then lifted across on the rails already laid, the remaining rails fixed in place, and, finally, the engine is moved. The rope is then coupled up to the tension, and adjusted. This is the only type of conveyor on which alignment and undulating floors have no serious economical bearing. It is efficient, and is easily lengthened, and in addition, since the design is so simple, the cost of upkeep and repairs are correspondingly small.

Two Conveyors Should be Used

The most economical method of working conveyor faces is to have two conveyors, one a few yards in advance of the other, delivering into one gate road. The road should be laid with a double track, having the bottom cut out to such an extent that the tubs will pass under the conveyors and be driven on from 10 to 12 yards in advance of the first conveyor, so as to allow of standing room for cars. Should circumstances not permit of a double road being carried, it is better to have two face conveyors delivering into one gate conveyor; and when within 100 yards of the limit to which it is intended to carry the workings forward, I would suggest, as a general practice, the use of a gate conveyor, thereby saving the cost of driving the last 100 yd. of road.

The Blackett conveyor, when used as a gate conveyor, can be lengthened to suit the advance of the face, and herein lies one of its advantages. It will also be clear that continuous running conveyors, such as the Blackett or Sutcliffe, are more suitable for delivering into gate conveyors than the other types described.

The efficiency of a conveyor depends manifestly on the rapidity with which the cars are changed, and this is one of the difficulties of conveyor work, more particularly so when a single road only is available, or when a gate conveyor is used. In order to cope with this difficulty, it is desirable to use as large a car as possible, and to keep the permanent mechanical haulage close to the face.

Great difficulty in the successful working of conveyors arises from the presence of small faults, not merely because they present obstructions in working by breaking the continuity of the coal face, but because they also give rise to an undulating floor and bad roof, and assist in bringing on pressure or weight.

Conveyors, an Aid to Safety

Conveyors are a valuable aid to the rapid advancement of the face; their use also involves the systematic setting of timber, as much labor is saved when moving the conveyor if the posting be regular; while the rapid advance in the face and the systematic setting of timber, make for increased safety to life and limb by securing a better roof. Weight upon the coal is beneficial in making the working easier if the coal is hard; but, if the coal is friable, weight tends to produce a large percentage of small coal. Here, again, speed in working is economical, since the weight has a shorter time in which to act; and as conveyor work involves keeping the face straight, weight is more uniformly distributed, and an increase in the percentage of round coal results. The effect of weight on the floor is to make it heave, more particularly if the floor be soft or moist, and cases have been known where machine mining and conveyor work have overcome this difficulty—again by promoting rapid working of the face. From these remarks, it will be gathered that where it is advisable to work with rapidity, machine holing and the use of conveyors are advantageous, as the speed of working is from five to six times as great as by hand labor when both are used, or, with conveyors alone, from two to two-and-a-half times as great.

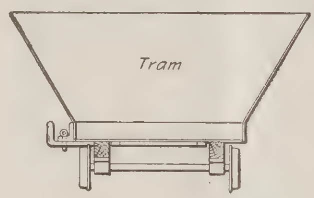

Fig. 6. Cross-section, Bunker Conveyor

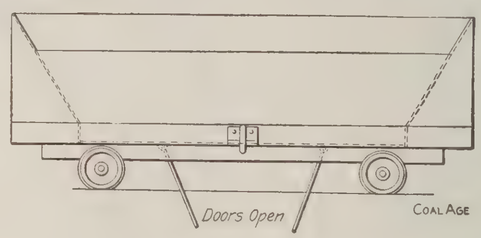

Fig. 7. Side View of Same Conveyor

Difficulty in Gob Filling

No reference has yet been made to the building of the pack or gob. In beds which do not make sufficient dirt, and which necessitate the making up of the gob, this is a difficult question; taking in filling for the gob is an expensive item, and affects seriously the results obtained from conveyor work, as, so far as I have observed, there are no conveyors which appear to be specifically designed to take in dirt, although most types are capable of doing so. If the gob is not built up with refuse, and especially if the seam is liable to great weight, the use of very strong timber on the gob side of the conveyor is unavoidable, in order to keep a good roof ahead, while allowing the roof to break down behind.

As regards the distribution of labor on the face, the great advantage of continuous-running conveyors, such as the Blackett and Sutcliffe, lies in the fact that every man gets an equal chance of using the conveyor. In other types, the men working near the delivery road will have the use of the conveyor for a greater length of time than those working further along the face, as, obviously, while the entire length of the conveyor passes the former, they have an added advantage in the slight delay required for unloading, whereas the latter only get a proportionately decreased length of conveyor and time for filling it. In order that the best possible output may be secured from the end of the conveyor-face, more labor is therefore usually concentrated there than at, or near, the delivery road.

The question of machine mining and conveyor work in very steep seams is an interesting problem. Cutters of the bar type can be used, and have been used, in seams of very high inclination; but, when the use of conveyors in steep seams is being considered, the "angle of rest" for the broken coal comes into play. This angle, which is not fixed, varies for different sizes and qualities of coal; where the seam, however, is too steep to allow of mechanical conveyors being used, a "natural" conveyor can frequently be made by using the floor as the bottom of a chute.

COAL AGE

Another Minimum Wage

The minimum wage provision demanded by the anthracite mine workers is wholly different, more logical and in accord with economic principles than that which the labor leaders and the miners of England are demanding.

In that country, the miners hope that arrangements may be made whereby men who cannot earn a minimum on a simple tonnage basis may receive what is rated as a living wage. The rate is not placed unreasonably high, but it is high enough that men who desire to shirk their task can avail themselves of the minimum clause to assist in trifling their time away at the working face on the pretence that they can accomplish little because they are laboring in an "abnormal place" where the presence of clays, faults, binders or rotten roof, makes coal extraction slow and difficult.

Economically the demand of the anthracite miners is sound. They ask that when the operator desires to pay them by the day instead of by piecework, they shall receive $3.50 for eight hours' work. We do not attempt to say whether this is or is not the wage the miner should receive. We do not make any pretensions to the possession of the infallibility of those who seem gifted with the power to decide the due compensation of laboring men. Some of these wiseacres are sure that a day's wage should not exceed a dollar. Others think ten times that pay is due to the man who bears the heat and burden of the day. But what we do say is that the proposed minimum is not merely a living wage, but an adequate provision for comfort and even for modest luxury.

No matter how frantically the dailies, influenced by the wishes of their readers, may try to show that the fight is for a living wage—the promise of the barest clothing and most meager fare—the truth is, the miners of the anthracite region are not engaged in such an heroic struggle. They are fighting for comforts. The stranger in anthracite towns will note the many saloons lining the streets, almost all owned by one-time miners who have accumulated money by fairly remunerative toil, and who are using their surplus to debauch their fellows.

Let it be added that if any anthracite miner lives in a hovel, it is because he so prefers, usually because years of use have made it more suited to his tastes than a larger house. He should receive commiseration not because he is poor, but because, in many cases, a chance to live better makes no appeal to his impoverished mind.

On the other hand, the high wages paid in the anthracite region have produced workingmen of a high class, owning their own homes and well performing family, local and national duties. These men, sober, honest, hard-working Americans of whatsoever extraction make more difficult the decision as to what a day's labor should bring.

Archives

A commendable practice of the state and federal governments has been to print and place in the hands of the public a series of archives, describing the events of public interest in past history. One notable feature of such an enterprise will be eagerly awaited toward the close of this year, when the state and federal statisticians will give us figures on mine tonnages and on the accidents which occurred in the far away year of 1911.

It is true that some state reports on mine tonnages and accidents are being delivered in this very month of February, but it may be added that all the state officials, who are trying to vindicate themselves by this apparent promptitude, have had a full eight months to complete their reports, as their fiscal year ended June 30.

From our Britannic cousins, who, if reports be duly credited, vie with those of Philadelphia for slow motion, we have long ago received a report of all mine accidents suffered in 1911, this report, covering three separate schedules of collieries, metalliferous mines and quarries.

The British report gives a statement for each mine-inspection district, and divides up accidents according to cause.

It is true the British advance proof does not cover several of the items of interest, because these cannot be obtained and tabulated in a week. The complete issue will come later. Nevertheless, there is no reason for our slowness. The coal companies should be urged to keep their books ready for the annual returns. They should keep on hand for immediate use the sizes and horsepowers of their equipment units. In all probability most inspectors do warn the superintendents and managers of their duties in this respect, for some inspectors have long ago filed their 1911 returns at the state capitols.

We confess the trouble appears to lie higher up. Fortunately, this year accidents of magnitude have been few, and there has been a breathing spell for the inspectors, during which time, this work, which must ultimately be done—be it sooner or later—could be hurried to completion. We know that the inspectors do hurry the coal operators into compliance, and the U. S. Geological Survey is likewise insistent, but why should any operator care? In what harm does his dilatoriness result? For the reports, when filed with an inspector, classified, summed and turned into the chief, are permitted to lie in disuse on the state files.

It is to be hoped that, year by year, operators, inspectors, statisticians, printers, proof readers and binders will learn that every day's delay makes the reports they render to the public more of the nature of archives than of returns, less useful to the reader and less true to the conditions existing at the date of issue.

Mine Refuge Chambers

Some time ago there was considerable agitation favoring the use of refuge chambers as a safety precaution in case of explosions and mine fires. Several coal companies in this country followed up the idea and provided their mines with such rooms. The provision of this type of safeguard is not nearly as general as the need warrants. The idea has been followed to a much greater extent in European mines, and the records show that in those emergencies when the plan was tested, satisfactory results were obtained.

Almost every week we read of some particular case where one or more men have been closed in a mine and perished through lack of respirable air and sufficient food, which might have been supplied to them if they could have reached a properly equipped refuge chamber. The actual need of such safety rooms in each particular mine, of course, is not an everyday occurrence; however, if the urgency for such protection comes to each company but once in a decade, the expenditure necessary to supply such provision is justified and the foresight of the management vindicated.

It would be a good idea if all mines were divided into districts completely separated one from the other by a fairly continuous pillar. In this plan, each district should be provided with a refuge chamber. In shaft mines, a fireproof chamber should also be located near the escape shaft.

In German mines, such refuge chambers are equipped with a protected telephone line put down through a drill hole into the chamber itself. Air is also supplied through this same hole. These emergency rooms are supplied with food, water, safety lamps, dry-cell electric lamps, oxygen-rescue apparatus, chemical fire-extinguishers, rolls of brattice cloth, and first-aid kits. The size of such a chamber should be determined largely by the physical characteristics of the coal seam, and especially by the number of men who are employed in the district which the refuge room is to serve.

In constructing such an emergency chamber, it is well to see that the room neck is long, the side pillars unusually thick, and the nearby entries as narrow as possible; the observance of these points reduces the amount of masonry work to a minimum. One authority suggests that each room should have two 30-in. entrances leading from the main, or cross entry and equipped with two or three heavy doors, opening inward, and fastened into the masonry.

In one case, at a European operation, the estimated cost of six underground chambers was three thousand dollars. It is probable that if this same mine had been supplied with electricity and compressed air, the cost would have been reduced to about two thousand dollars.

Where there is no compressed air, the mining company would have to supply small motor-driven compressors, or better still, hand ventilators designed to circulate air through the drill holes—one hole being used as an intake and the other hole as an exhaust. Also, it would be easily possible to arrange and perfect a plan on the surface, whereby air could be sent down one drill hole into the rescue chamber. This would avoid the possibility of the ventilation plan failing through the destruction of underground electric or compressed-air lines.

The Engineer and Electricity

It must have seemed a reasonable conclusion some ten or fifteen years ago that the application of electricity to mining would advance more rapidly than along most other lines because as a source of power it is so peculiarly suited to the problem presented by the average mine. And yet, although it has been successfully applied to practically every phase of coal-mining work, from shot-firing to haulage, it cannot be said to have been either so rapidly or so generally adopted as its merits would lead one to expect. Indeed, it would seem to be, as was said recently at a meeting of the North of England Institute of Electrical Engineers, that in the application of electricity to some of the problems in coal mining, the engineer has shown an excessive amount of caution—even timidity.

While it is not intended to condone, much less advocate, the practice of taking any risks in connection with a fiery or dusty mine, and while it is recognized that perhaps the first duty of the engineer is to secure the safety of the miner, still it should be pointed out that in the application of electricity to coal mining, there is presented no problem that reasonable ingenuity cannot solve.

Unfortunately, where an element of uncertainty is found to exist in regard to the use of electricity in a particular instance there seems to be a tendency to take refuge in repressive legislation rather than in trusting to the inventive capabilities of the present day. Are we becoming less resourceful as well as more cautious, or is there here evidence of a lamentable disposition to let well enough alone, even in the face of needs so pressing as to show conclusively that all is not "well enough"?

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Sealing off a Mine Fire

(Continued from Feb. 17)

Letter No. 28—If there is a fire at the face of a pair of butt entries with an air current flowing up the one and down the other, we would seal it off in the following manner:

After ascertaining the local conditions as far as possible, and finding that no difficulties peculiar to the location were to be apprehended, we would approach the fire as near as possible with as light a current of air as our men could work in. If the last crosscut could not be reached, we would travel up to one which was closed, knock the stopping down, and await the effect of practically clearing the crosscut of smoke. This accomplished, we would erect a brattice cloth partition from the corner of the crosscut half way across the return air course. This would enable us to reach such a position as to allow of the erection of a cloth brattice and later of a board stopping across the return air course. We would then close the intake with a board brattice. Later brick stoppings should be put in.

The reason for closing the outlet first is to cut away from the fire the accumulated volume of gases between the point of location of the first stopping and the up-cast shaft. This method permits the sealing of a fire with the minimum of danger.

N. D. MONSARRAT,
2nd Vice-President.
D. H. WILLIAMS,
District Supt.
Sunday Creek Co., Glouster, Ohio.

Letter No. 29—I have read the Foreword in the issue of COAL AGE, Jan. 20, 1912, and make the following deductions:

Manager was notified of fire and location of same; men had started to work inside of fire; hoisting of coal had begun, at the mine; relay squads were fighting fire; main entry was the intake, the back entry, the return; mine gave off gas; was examined by fireboss. Whatever may have been the origin of the fire it had not been in progress long, and it may be assumed that no accumulation of gas had occurred, in the 12 or 14 hours since the last shift quit on Tuesday, 5 p.m. From the reports it appears there is no disturbance of the ventilating current.

It having been decided to seal off this fire, I would open up the crosscut between the main and back entries at the nearest possible point to the fire, so as to short circuit the air current at this point and prevent its reaching the fire. I would then run a line of brattice (Fig. 1) from this crosscut up the main entry, select a good place as close to the fire as safety would permit, and build the first stopping there on the main entry. I would so arrange the brattice that it would carry only sufficient air to supply the men at work and keep away the smoke and fumes. The brattice must be hastily built of any material at hand; a board stopping will do. In the back entry, I would erect the same kind of brattice, but it would be necessary to carry more air forward in the back entry, owing to the smoke and fumes coming down this entry from the fire.

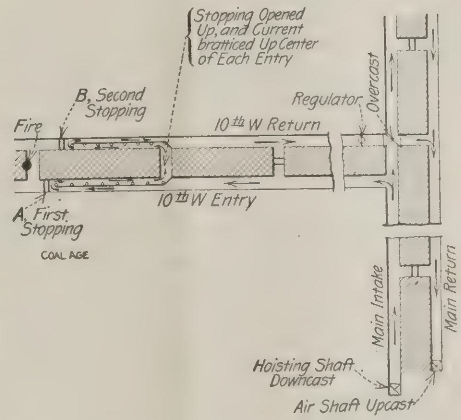

FIG. 1. SHOWING PROPOSED MANNER OF STOPPING OFF A MINE FIRE

I have seen it suggested (it is a German idea) that a good temporary stopping can be built from bales of hay. These bales are first stacked in the entry and wedged tightly with loose hay to make the stopping as nearly air-tight as possible, and then the hay is wetted, which causes it to swell. This makes a tight stopping, and the hay is said to be practically incombustible when properly baled. If no water line was available I would use a bucket brigade. The baling wire holding the hay should be cut before it is wetted, so as to allow of the free expansion of the hay.

Even if the crosscut was not opened up as I have described, I would place the first stopping on the main entry, as close to the seat of the fire as practicable. Then, when building the second stopping on the return airway, I would still be able to carry air by bratticing from the main-intake air course.

From the description given in the Foreword of Jan. 20, I have assumed the circulation to be as shown by the arrows, in the accompanying sketch, Fig. 1. Assuming this arrangement is correct, perhaps the quickest way to handle this fire after building the first stopping on the intake would be to build the second stopping behind the regulator, although if conditions would permit I should want to place the second stopping nearer to the seat of the fire and reinforce by building other stoppings, if necessary. In any case, substantial stoppings should be built immediately after and in front of the two temporary stoppings. These can be built of any material available.

In our state, one of the largest operating coal companies, the Norwestern Improvement Company, build all of their stoppings with logs, six, eight and ten feet long, the ends being wedged and the whole plastered. Broken mine timbers can often be utilized for this work. Each stopping is formed of a double wall of timber, and the space between is filled with clay or sand. Pipes should be built into each stopping, one at the bottom for draining the water, and the other at the top for testing the air for gas, in the inclosed space. This will permit of the taking of samples of the air inside the inclosure, in order to make a test from time to time, of its gaseous condition. These pipes are plugged. If it is desired, a steam line may be attached to the end of one of the pipes, at any time, and live steam introduced into the area to extinguish or dampen down the fire.

Conditions must always determine whether it is better to close the intake or the return airway first, in any particular case. In the case described in the Foreword, I think the first place for the stopping to be built would be on the intake, whether the crosscut was open or not.

J. B. McDERMOTT,
State Coal Mine Inspector.
Helena, Mont.

Letter No. 30—The question under discussion on mine fires, as I understand it, is to seal off a fire which has gotten beyond control. The words "beyond control" certainly mean that we have a serious fire, one which covers quite an area

and is giving off great volumes of poisonous fumes and smoke.

The first step to be taken is to short-circuit the air in the nearest crosscut to the fire. I would then build a stopping on the intake entry, which could be done in practically pure air; then close the return airway, which can usually be done without much difficulty after the intake has been closed, as it has been my experience that the volume of fumes and smoke gradually diminishes after the first stopping has been completed.

I would certainly consider it a dangerous practice to take men beyond the intake entry a distance of from 40 to 60 ft. to get into the return airway to build the first stopping. It is a common occurrence to have a heavy fall in the burning section, which forces the fumes and smoke out into the intake entry, making it necessary to retreat to fresh air as quickly as possible. Now if men were required to travel a distance of from 60 to 80 ft. through these fumes and smoke, it is probable that some of them would get down and the workmen would certainly become disorganized and the work delayed. An accident to the fan would have practically the same result. I fear that some of the readers have not considered the extent of the fire; however, the question is plain, and refers to fires which have gotten *beyond control*.

W. F. MANDT.

Longacre, W. Va.

Letter No. 31—A definite answer to the mine-fire problem cannot be given, as every difficulty demands its own solution and the local conditions must govern. The principal thing to be done is to attack the fire *promptly*, and for this reason the work of building stoppings should be begun at the earliest possible moment. First decide where the stoppings on the intake and return are to be built and proceed with the work at once.

While decision is being made as to which stopping to close first, the framework for a heavy door stopping can be erected and the heavy door itself made. This door can be arranged in a variety of ways: It may be installed so as to be closed by a heavy weight attached to a rope over a pulley, a trigger attachment holding the door open till withdrawn by means of a long rope extending to the surface, if necessary. Or the door can be closed by the direct pull of the rope.

The door-frames having been built and the doors hung, these can be left open until the men have *all been withdrawn* from the mine. Then the doors are closed simultaneously or in the order which has been in the meantime decided upon by the management. By this means the men are all in a place of safety when the doors are closed. This plan was first used in 1906 by the Lehigh Valley Coal Company engineers. If the rope is to be used to close the door by a direct pull, it can also later be used to pull down the door without entering the mine in case it is the desire to do so. This was so in the case noted above, where the door was later demolished by means of the rope.

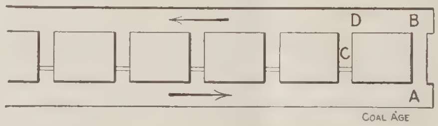
This plan often requires a long rope, but rope is cheap in comparison with the cost of a mine fire. A hoisting or haulage engine is usually necessary when the rope is long and no pulleys need be placed, as the engine can pull the rope around corners and pillars if necessary. If the door is not to be demolished later, a weak piece of rope should be inserted near the door to break when the door is closed.

A. B. JESSUP,
Mining Engineer.

Lehigh Valley Coal Co.,
Wilkes-Barre, Penn.

Letter No. 32—I wish to express my views concerning the best method of closing off a mine fire. I have assisted in subduing several during the 56 years I have been connected with mines.

Ten years of this period were spent in the bituminous-coal field of South Wales, which pitches from 15 deg. up to about 45 deg.; twelve years in the semibituminous longwall workings in the same coal field, and the remaining 34 years in the anthracite-coal field of the Wyoming valley, Penn.



ILLUSTRATING CONDITIONS EXISTING AT MINE FIRE

Whether the intake or the return is closed first is not material if the section of the mine where the fire is located is not very gassy. But when feeders or blowers are numerous, and strong in pressure, it is important that the return airway should be closed first. Twice I have built stoppings in the intake before I closed off the return, when the place was very gassy as described above, and both times an explosion took place. But not on even a single occasion did the gas explode when the return was shut off first. It seems that the intake airway quickly fills with an explosive mixture and this reaches the fire before the smoke produced from its combustion becomes dense or thick enough to prevent such an explosion. But when the return airway is closed first it produces such a heavy incombustible atmosphere about the seat of the fire, that any firedamp reaching the same becomes nonexplosive. If two places are driven parallel with crosscuts at stated intervals, as shown in accompanying sketch, of course each crosscut is closed by a stopping as a new one is completed. Therefore, the intake current passes by A, and returns at D.

Assuming the fire is at B and that said fire becomes beyond control, the first thing that must be done is to build a temporary door in crosscut C. Then the stopping in that same crosscut should be torn down. This secures a passable approach to the return airway B so that the quantity of air coursing at B is reduced. Also by this means material can be accumulated near the point D for building up the stopping at that point. All the props must be erected before any boarding is commenced. If much CO or CO_2 is present in the return from the fire, the men must be changed very often; in fact, at five- or ten-minute intervals. Then, when everything is ready, put on the boards quickly from bottom to roof. In so doing the density of the smoke becomes such that part of it fills the heading between B and A, and therefore prevents the accumulated firedamp from becoming explosive at the seat of the fire. No doubt you will find many opinions in the matter, and each man as positive as his opponent that his methods are correct, but those who have gone through the "fire of experience" under different prevailing conditions will hesitate long before they will allow the intake to be closed first.

W. D. OWENS,
District Superintendent.
Lehigh Valley Coal Co., Pittston, Penn.

Susie, Wyoming, Explosion

No doubt you have received a report on the explosion that occurred at mine No. 4 of the Kemmerer Coal Co., Jan. 20, 1912. I inclose a rough sketch of the mine, but did not have time to put in the rooms. I have made this sketch from memory, not having the map before me, but I believe it represents correctly the arrangement of the entries.

Referring to the sketch, there was a rock stopping at A, a box regulator at B, and between these, at C, was a canvas stopping that had been cleated down tight at the top and bottom. The rock stopping at A and the regulator at B were each blown toward each other by the force of the explosion. Under these conditions, I would like to ask, how would you account for the fact that the canvas stopping was not blown out, but was still in place after the regulator and the rock stopping were both found to have been destroyed? As I stated, each of these were blown in a direction toward the foot of the return airway. I would like to have COAL AGE and any other of its readers who have had similar experiences offer some explanation of the reason why this canvas stopping was not destroyed.

W. H. GEORGE.

Frontier, Wyo.

It rarely happens that a mine explosion of any considerable importance oc-

curs where the later investigation does not reveal many things that appear to be almost inexplicable. We are, however, confronted with the fact of their existence, and the question asking for an explanation is therefore a reasonable one.

It reminds one of the story of a prisoner who was found by a friend in a prison cell. After the first expression of surprise on the part of his friend, the prisoner was asked, "But how did you come here; what did you do?" The story of the arrest was briefly told. "But," said the astonished friend, "they could not jail you for that." The prisoner's response was, "Whether they *could* or *could not* is not the question; they *did*, and I am here."

So in a mine explosion, it is idle to talk of whether this or that could or could not have taken place. If it is a fact that is presented, the question, "How did it occur?" is a proper one. Our correspondent states that the tightly cleated canvas brattice at *C* was not destroyed by the blast that blew out the much stronger rock stopping and the box regulator, on either side of it, each of these being blown toward the foot of the return slope.

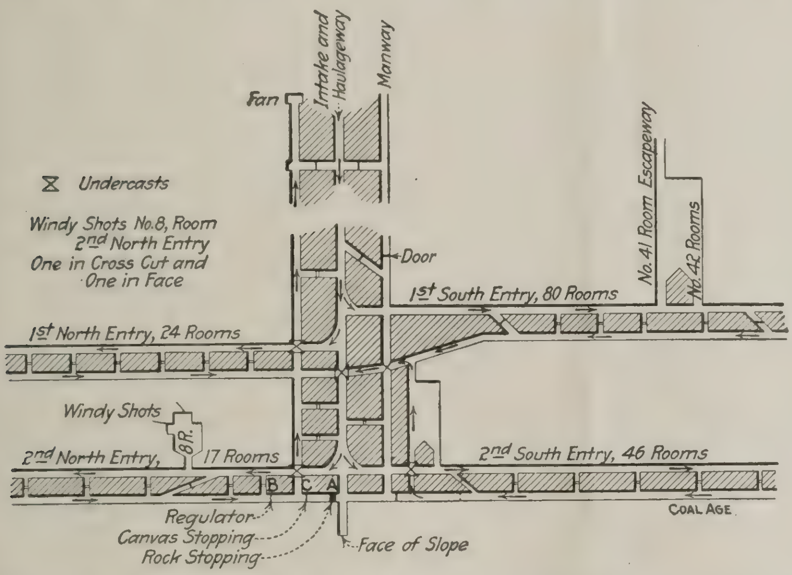
Assuming that this is a statement of fact and that the canvas brattice at *C* was not injured, the natural conclusion is that either there was a balance of forces exerted on the opposite sides of the canvas stopping; or that the force of the blast on each side was killed or wholly absorbed by the work done before it reached the canvas.

The first of these two assumptions appears the more probable one when one studies the airways and follows on the map the direction the blast would travel in reaching the mine opening. From our information the explosion originated in one of the rooms on the second north entry and was probably caused by one or more blown-out shots. The map or sketch sent us by our correspondent and which is the only information at hand at present, shows that if the expanding gases formed by the explosion took the natural course, feeding on the fresh air of the intake airway, the main haulage slope would be the principal outlet. If the initial force of the explosion were sufficiently strong, much of the shock of the blast would also be exerted up the return slope toward the fan. This, however, would be determined only by the character of the explosion, whether it was chiefly a gas or dust explosion.

To obtain an intelligent idea and solution of what took place at the moment of the explosion, the mine must be considered as a cul-de-sac, which in point of fact it was. In this case, the force of the explosion is exerted from within outward in the direction of the openings. The resistance offered by the airways to the gases thus propelled at a high velocity through the slope causes a kick-back on all the stoppings in the immediate vicinity.

It is a law of mechanics that action and reaction are always equal. If a man jumps forward he exerts an equal reaction, in the opposite direction, on the ground. The action of an explosion of gas in a mine is in every respect similar. As a consequence, two stoppings inby from *B* are blown out by the initial blast and almost simultaneously there is exerted the full pressure of the blast on both the regulator at *B* and the rock stopping at *A*. Both of these pressures would be exerted toward the canvas brattice at *C*. The pressure at *B*, however, is the direct pressure remaining after destroying the stoppings mentioned, while the pressure that blew down the rock stopping at *A* would be a kick-back due to the resistance met in propelling the gases up the slope to the mine openings.

This is only offered as a possible, but at the same time a reasonable solution. It is an interesting question and COAL AGE hopes many of its readers will offer their own solutions.



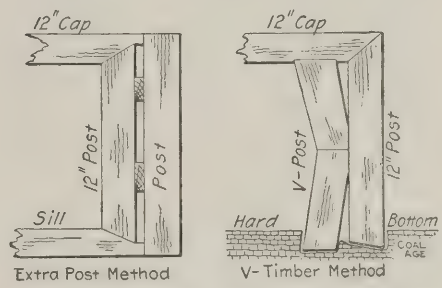
SKETCH PLAN, SHOWING A PORTION OF MINE NO. 4, KEMMERER COAL CO., SUSIE, WYOMING

Timber Framing for Side Pressures

With reference to the article appearing in your issue of COAL AGE, under date of Jan. 20, 1912, regarding timber framing for side pressure, by Joseph Virgin, of Plymouth, W. Va., I agree with him that when the timbers are notched, the leg or cap will invariably split, before either the post or cap has taken the weight they are expected to sustain. In this sketch, however, the small angular piece nailed in the interior corners does not add materially to the strength of either cap or leg; the only support it gives is the resistance of the nail, and we get practically no strength from the piece of timber itself.

Again, I know Mr. Virgin personally, and I am sure a man of his experience would not set the post at an angle of 45° from the perpendicular to support a side pressure, even if the ends or the upper corners were cut at such an angle.

I realize that he has increased the size of the post from 10 to 12 in., making it 2 in. thicker than the cap, but in my opinion, the pitch given the leg counteracts the extra thickness given the upright leg. The side pressure is the same on the leg, no matter what angle it is set on, but it also has to sustain a top pressure, in proportion to the degree it is set from the perpendicular.



DOUBLE TIMBERS FOR SIDE PRESSURE

Therefore, I think the best way to resist the side pressures, is to place extra support in the side timber. This may be done either by increasing its thickness, by putting an extra post at the back of the leg, or by using timber in the shape of a V, with the cap and the floor for the two ends to rest on, and joined in the center of leg, as shown in the accompanying sketches. The tendency of the side pressure would then be to push up the cap, or down in the floor, or both, and in this way we get the extra strength of these supports added to the strength of the leg.

MINE SUPERINTENDENT.

Johnstown, Penn.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Is Carbon Dioxide a Poisonous Gas?

Will COAL AGE please explain exactly what is or should be meant by a "poisonous gas," in mining; and state whether carbon dioxide should be classed as a poisonous mine gas?

MEMBER FIRST-AID CORPS.

Birmingham, Ala.

The meaning of poisonous is "injurious to health or tending to destroy life by impairing its functions." There is no doubt but that there are wide degrees of poisonous qualities.

Some poisons destroy life almost in an instant. Such are hydrocyanic acid, carbolic acid, carbon monoxide gas. Other poisons are slow in their action, but none the less sure in effect unless relief is obtained.

In mining practice, it is customary to class as poisonous only, two of the common mine gases; namely, carbon monoxide (CO) and hydrogen sulphide (H_2S). Carbon dioxide (CO_2) has not been considered as a poisonous mine gas. That is not to say, however, that carbon dioxide is not poisonous.

A clearer understanding will be gained by comparing this gas with pure nitrogen, which forms practically four-fifths of the volume of the air we breath, and which cannot be said to have any poisonous qualities whatever.

Pure nitrogen could not be breathed, for any time, without causing death by suffocation; but this is not due to any action of the nitrogen on the blood or tissues of the body. It is due simply to the exclusion of oxygen from the lungs, which oxygen is necessary to life. Likewise, when pure carbon dioxide is breathed, for any time, death ensues, because of the exclusion of the necessary oxygen from the lungs. However, while the presence of so large a proportion of nitrogen in the life-sustaining air amply warrants the assumption that nitrogen has no poisonous qualities whatever; there is not the same warrant of assurance in respect to carbon dioxide, which is the discarded refuse—the chief waste product in sustaining life. It would be unwarrantable to assume or even suggest that this refuse gas possesses *no* poisonous qualities.

In the mine, carbon dioxide forms a variable but important part of the mixture known as *blackdamp;* the other chief constituent being air poor in oxygen. As is well known, the breathing of blackdamp for a greater or less period of time produces drowsiness, headache, nausea, followed by ache in the back and limbs. These symptons indicate the action of insidious poison that slowly impairs the functions of life. Is it to be attributed to the nitrogen in the residual air; or to the vital functions not receiving a sufficiency of oxygen; or to a poisonous action of carbon dioxide? All of these possibilities exist in the noxious blackdamp. To answer this question we must look for a further comparison of these gases, under a similar depletion of the normal percentage of oxygen.

Compare, for example, the fatal artificial atmospheres formed by adding nitrogen and carbon dioxide, respectively to pure air until a mixture fatal to life in a like period of time, is produced. The lowest percentages fatal to life when these gases, respectively, are added to pure air are shown in the following table, "Mine Gases and Explosions," page 144:

FATAL ARTIFICIAL ATMOSPHERES FORMED BY ADDING NITROGEN AND CARBON DIOXIDE, RESPECTIVELY TO AIR, SHOWING COMPOSITION OF MIXTURE AND PERCENTAGE OF GAS ADDED

Gas added to pure air	Composition of mixture (Per cent.) N_2	O_2	CO_2	Proportion of gas added
Nitrogen	93.0	7.0	...	2 volumes
Carbon dioxide	64.9	17.1	18.0	$^2/_9$ volume

The above shows clearly that carbon dioxide acts on the vital organisms in another way than to produce simply suffocation by the exclusion of oxygen in sufficient quantity from the lungs. Fatal effect is reached by the addition of but $^2/_9$ volume of carbon dioxide to 1 volume of air, depleting the oxygen to only 17.1% (normal 20.9%). In the case of nitrogen, it is necessary to add twice the volume of the air, thereby depleting the oxygen content to 7%, before producing a fatal atmosphere.

What Is a Combustible Gas?

Is oxygen a combustible gas? The textbooks say it is a supporter of combustion, but why is it not also combustible? What is a combustible gas?

CHEMIST.

Denver, Colo.

Oxygen is the universal "supporter of combustion," because it is the active agent in the atmosphere that makes combustion generally, possible. The process of combustion in oxygen is termed "oxidation."

All combustion, however, is not oxidation, although all oxidation *is* combustion, in the broad meaning of the term. It may mean the slow oxidation of iron in a damp atmosphere, or the slow combustion of fine coal in the gob, in a mine; or it may refer to the rapid combustion of wood, coal, or other combustible, in a blazing fire. In each case, the iron, coal, wood, etc., is consumed and is no longer iron, coal, or wood. Instead, there remains the oxide of iron, or oxide of carbon—a new substance; and the change, in each case, is some form of combustion.

Combustion may take place in other atmospheres than oxygen; but it is not then oxidation, unless, perchance, oxygen is burned in an atmosphere of hydrogen. When hydrogen is burned in an atmosphere of chlorine; or chlorine is burned in hydrogen, combustion takes place, but there is no oxidation. The hydrogen and chlorine are consumed, and a new substance, hydrogen chloride is formed. The burning of sulphur in hydrogen produces hydrogen sulphide.

It is clear that the question of whether any gas or other substance is or is not combustible is simply relative, depending on the atmosphere in which the combustion, if any, must take place. Thus, wood, coal, oil, or other substances that are highly combustible in air are not combustible in an atmosphere of nitrogen, carbon dioxide, or other gas containing no available oxygen.

Oxygen will not burn in air any more than it would in nitrogen or carbon dioxide; because air contains no gas for which oxygen has sufficient affinity to cause chemical union under these conditions. Oxygen is therefore not combustible in air, but it is combustible in hydrogen. Likewise, and for the same reason, chlorine gas is not combustible in air, but burns readily in an atmosphere of hydrogen.

Strictly speaking, from a scientific standpoint, it is not a complete or exact statement to speak of any gas or other substance as "combustible"; except where it is clearly understood that the meaning is, "combustible in air." This is the usual meaning when not otherwise stated.

A gas or any substance whatever is combustible in a given atmosphere when it is capable of being consumed in that atmosphere.

Examination Questions

Questions for Beginners

Mine Resistance

Ques.—What produces the resistance that a mine or airway offers to the passage of the air current?

Ans.—The resistance is due both to the friction of the air rubbing on the sides, top and bottom of the airway, and the obstructions met by the current in its passage, such as timbers, falls of roof, contracted breakthroughs or crosscuts, sharp bends in the entries, etc.

Ques.—How is the resistance of a mine commonly measured?

Ans.—Resistance in ventilation is determined by the ventilating pressure it produces in the airway or fan-drift. To ascertain the ventilating pressure it is necessary to measure both the inches of water gage and the area of the airway in sq.ft. Then, since 1 in. of water gage corresponds to a pressure of 5.2 lb. per sq.ft., the total ventilating pressure is found by multiplying the inches of water gage by 5.2, and that product by the area of the airway. Thus, calling the resistance R; the unit of ventilating pressure or pressure per sq.ft. p; the sectional area of airway a; and the water gage $w.g.$; the formula for mine resistance is

$$R = p\,a = 5.2 \times w.g. \times a.$$

Example—Find the mine resistance when the water gage reads 2.5 in., in an airway 6x10 ft. in cross-section.

Solution — $R = 5.2 \times 2.5\,(6 \times 10) = 780$ lb.

Ques.—(a) What is meant by the coefficient of friction in mine ventilation. (b) Give its symbol and value commonly used.

Ans.—(a) The coefficient of friction is the *unit of resistance,* which means the resistance per sq.ft. of rubbing surface, for a velocity of 1 ft. per min., in the air current.

(b) The common symbol for the coefficient of friction and its value are

$$k = 0.00000002\ lb.$$

Ques.—(a) Upon what does the resistance of a mine or airway depend? (b) How does the resistance of a mine or airway vary?

Ans.—(a) Resistance depends on three factors; namely: 1, coefficient of friction k; 2, rubbing surface s; 3, velocity of air current v.

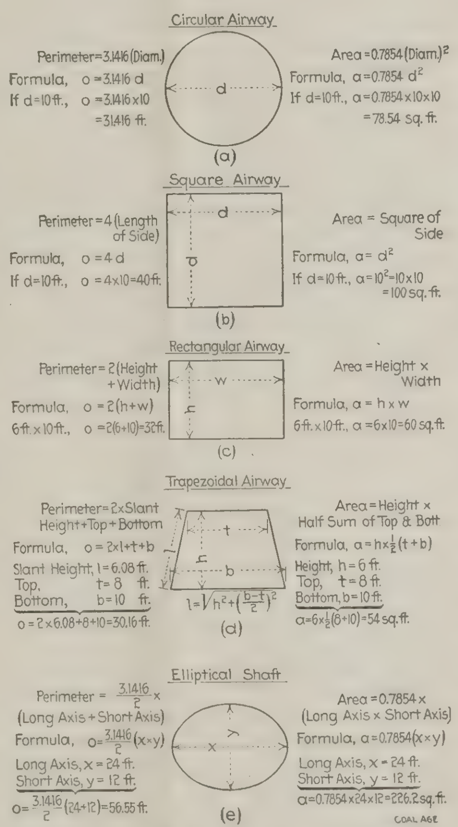
(b) Resistance varies as the rubbing surface s, and the square of the velocity of the air current.

Ques.—Give the formula for calculating the mine resistance when the rubbing surface and the velocity of air current are given.

Ans.—The formula for mine resistance calculated from the rubbing surface s and the velocity of the current v, is

$$R = k\,s\,v^2.$$

Example—Find the resistance of a mine when the size of the airways is 6x8 ft. and 5000 ft. long, including the return; and the air is traveling with a velocity of 8 ft. per sec.



PERIMETER AND AREA OF AIRWAYS OF DIFFERENT SECTION

Solution—First, find the rubbing surface by multiplying the perimeter of the airway by its length; thus,

$$s = 2(6 + 8) \times 5000 = 140{,}000\ sq.ft.$$

The velocity of the current is

$$v = 8 \times 60 = 480\ ft.\ per\ min.$$

Then, the mine resistance is

$$R = 0.00000002 \times 140{,}000 \times 480^2$$

$$R = 645.12\ lb.$$

Example—(a) Find the unit of ventilating pressure in the last example. (b) What is the water gage?

Solution—

(a) $$p = \frac{Resistance}{Area}$$

$$p = \frac{645.12}{48} = 13.44\ lb.\ per\ sq.ft.$$

(b) $$w.g. = \frac{p}{5.2} = 0.26\ in.,\ nearly$$

Ques.—Does splitting the air current in a mine change the mine resistance; and, if so, explain the effect of splitting.

Ans.—When the air in a mine is "split," the current is divided between two or more airways. The rubbing surface remains the same; but the *area of passage* in the mine is increased in proportion to the number of air currents traveling through the mine. It is evident that an airway 10x10 ft., 5000 ft. long, has a rubbing surface of $4 \times 10 \times 5000 = 200{,}000$ sq.ft., and an area of $10 \times 10 = 100$ sq.ft. Now, if the air passing in this mine in a single current can be made to travel the same entries in, say 2 splits, each 10x10 ft., 2500 ft. long, the rubbing surface is still $2\,(4 \times 10 \times 2500) = 200{,}000$ sq.ft., but the area is $2\,(10 \times 10) = 200$ sq.ft., or double the original area.

Now taking, first, a simple case where the air is divided at the mine entrance and passes through the mine in two separate currents, if the *power* producing the circulation remains the same, the rubbing surface being unchanged, the velocity of the air passing in the 2 splits will be the same as the velocity in the original single airway. This is true, because the velocity of the air depends only on the rubbing surface and the power applied to the air, without regard to the area of the airway. Thus, 10 hp. applied to a 10x10-ft. airway will produce the same velocity as this power would produce in a 6x8-ft. airway.

The mine resistance depends only on the rubbing surface and the velocity of the air. Hence, for the same power on the air, the mine resistance will not be changed by splitting the air current into two or more separate splits.

In common practice, however, the air is not divided till after it has traveled a greater or less distance through the shaft and main airway, and likewise the return current must travel the main return airway and upcast shaft in a single current, which reduces the power on the air at the point where the air is split. In this case, both the velocity and the resistance are reduced by splitting.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Mine Accidents and Their Prevention

The illustrations on our front cover are taken from the book, "Mine Accidents and their Prevention," written by J. H. Dague and S. J. Phillips under the supervision of R. A. Phillips, general manager, and C. E. Tobey, superintendent of the mining department of the Delaware, Lackawanna and Western Railroad Company. The book is published at the expense of that company for the instruction of their mine workers and certainly reflects great credit on all concerned.

The publication is intended largely for mine workers having a limited knowledge of English and is planned not only to instruct them in their mining duties, but to give them a working knowledge of the words used in describing their work and the tools they employ. Though the book is complete, it will be supplemented by the verbal instructions of the mine foreman, and to make his teaching successful, the European miner is provided in this book with a sufficient vocabulary whereby foreman and miner can make themselves mutually understood.

The Use of Pictures in Teaching

Teaching by pictures is not new. It has been proved by psychologists that a student will remember words better by association with pictures of the objects they represent than by placing those words side by side with their translations into the language of the pupil. This was exhibited some few years ago in the submission of Japanese words to pupils together with pictures illustrating them. Other Japanese words, together with their English equivalents, were likewise submitted, but it was found that the pictured words were more largely retained by the memory.

The immigrant is moreover possessed of a small vocabulary and one not usually correctly comprehended by him, and consequently a picture is more valuable than any other instructing medium. Many miners were employed as farm laborers in their home countries, and the objects in the mines they have to name for themselves with words which are doubtless not recognized in the technological dictionaries of their own or any country. Consequently translation is not easy.

But it is not nouns which principally try the foreigner. The elusive verbs, prepositions, adjectives and adverbs are his main trouble, and so the Roberts system of instruction is followed in this admirable mining primer. The sentences grow progressively harder, starting with "The miner is in the chamber" and "He lights a squib," to longer sentences which describe the pictures with which our front cover is graced: "The miners drill is too small at the sharp end. This drill will not make a hole large enough for the cartridge. The miner drilled a hole with this drill," and so on. Following these sentences are statements significantly printed in red ink: "He tries to force the cartridge into the hole with the drill. The drill strikes a spark. The spark flies into the powder. The spark sets off the powder." Down the side of the page are words used for the first time in the lessons and to which the attention of the student and his instructor is drawn. The book ends with notes on "how to become an American citizen" and gives questions, an applicant may be required to answer.

So excellent a book has not come to our notice for some time. It is an evidence that one at least of the anthracite coal companies has the training, citizenship and safety of its employees closely at heart. It is to be hoped that means may be taken to make such instruction general.

The Other Half

By Charles L. Fay

(Continued from Feb. 17.)

There are social students, like Dr. Steiner, who make a careful study of living conditions by a life in the environment, within which they try to uplift the worker, whose objects are not self-seeking and whose solutions are not premature. But what of some of the professional, "just out of school" investigators and writers for publicity bureaus and current literature? Is it not possible that some young and well meaning enthusiasts, fresh from college and obsessed by a spirit of socialism gained from socialistic, though scholarly literature and society environment, go to a "field" with their ideas of the conditions already *fixed* and then absorb only such incidents as will brace their fixed ideas? The mind of this type of investigator is so completely—though unconsciously—impervious on the one side and sponge-like on the other that part of the truth is automatically resisted while another part is as automatically absorbed.

Then, again, are not some investigators too "hurried" in their work? To cite a case in point. An investigator and writer will visit a coal-mining community to get data for an article on the conditions of mine workers. This writer will spend about two days in the "field," see the one or two labor leaders and perhaps one or two mine superintendents and ride through the community by automobiles, trolley cars and trains, looking at back yards, streets, water supply, beer wagons and "living conditions" from the windows of the fast moving vehicles, while his knowledge of local labor conditions is gained from a half-dozen brief interviews. Then, away to the hotel, pullman car or home office and pen picture after pen picture is produced by this facile writer. Some societies seem to believe in this type of investigation, some magazines innocently accept the "dope" while yellow journals "devour" it and cry for more.

This and similar types of investigation are back of a great deal of data which go in printed form to the public and contribute only too largely toward the forming of what we know as public sentiment.

Miners and operators welcome, I am sure, fair investigation of social conditions in coal-mining communities, when the investigation is carefully made by competent and unprejudiced investigators. But when writers are too biased to draw fair conclusions, too superficial in their investigations and treatment of a subject to assure the presentation of all facts or make *studies* simply to get "copy" for carelessly edited or yellow journals, then resentment is justifiable.

The loss to society and the danger, however, is in the power for evil in the wrong public sentiment thus created and in the prejudices thus stimulated.

Treatment for Carbon Monoxide

The treatment for carbon-monoxide poisoning is very simple. Remove the patient to the fresh air without delay. Keep the patient warm and administer oxygen at once. If necessary administer artificial respiration. This can be done by placing the patient in the prone position with the head turned to one side. Then press on the lower ribs at the rate of fifteen times a minute. When the patient has recovered, forbid all exertion and watch carefully for some time as relapses are apt to occur. Do not attempt to treat carbon-monoxide poisoning in an atmosphere that contains even a small quantity of that gas.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Interstate Commerce Commission has rendered a decision in the case of the Elmore-Benjamin Coal Co. vs. the Cleveland, Cincinnati, Chicago & St. Louis Ry. Co. *et al.*

The facts in the case show that in December, 1910, by permission of the Illinois railroad and warehouse commission, the carriers engaged in transporting bituminous coal to Chicago from the fields in Williamson and Franklin Counties, Ill., increased their rate 7c. per ton. At the same time a similar advance was permitted by the Interstate Commerce Commission in the rate to Chicago from the adjacent, or Harrisburg, field in Saline County, Ill., the movement from this district being interstate. On June 22, 1911, this advance was applied to the joint rate to Milwaukee. Under this adjustment the rate from Williamson and Franklin Counties continued to be 3c. per ton higher than the rate from Saline County. Effective in July, 1911, defendants attempted to equalize these rates by increasing the latter 3c., but the proposed advance was suspended by order of the commission. Complaints were filed attacking both the actual and proposed advances from the Harrisburg field to Chicago and points beyond, particularly to Milwaukee.

Finding of Commission

After full hearing and investigation, it has been held (1) That the advance of 7c. per ton is not found to be unreasonable or unjustly discriminatory nor to subject the Harrisburg field, Milwaukee, or the traffic in question, to any undue or unreasonable preference or disadvantage. (2) That the defendants have sustained the burden of proving the propriety of the proposed advance of 3c. per ton. Orders will be issued dismissing the complaint and vacating the orders of suspension.

In speaking of the conditions of competition in the coal trade which gave rise to this case, the commission says that the testimony introduced by complainants in these cases was largely addressed to the commercial competition which coal from the Harrisburg district meets at Chicago and Milwaukee. At Milwaukee this competition is from what may be called Appalachian coal, which moves by rail from the mines to the lower lake ports and thence by vessel. The allegations of the complaint indicate that this coal is delivered at Milwaukee at a total rate much lower than the former rate of $1.45 from the Harrisburg district.

It developed at the hearing, however, that the all-rail rate from Harrisburg to Milwaukee embraces services not included under the rail-and-lake combination from the Appalachian Mountains to Milwaukee, and that the total cost of getting a ton of coal from the Pittsburg or Eastern districts to Milwaukee was not simply the sum of the rail rates from the Eastern mines to the lower lake ports plus the lake rate to Milwaukee, whatever that might be, but involved the cost of unloading the vessel at the dock at Milwaukee, loading cars from the stores at the dock and switching from the dock to the required deliveries.

Coal from the Harrisburg field appears to be of fairly high grade as compared with Indiana-Illinois coal generally. Indeed, it may be stated that it is on the whole of superior quality, but it cannot be stored like Eastern coal without deterioration and it does not rank as high in heat-producing power as coal from the Eastern districts with which it competes.

Freight on Mine Car Wheels

The Interstate Commerce Commission has issued its decision in the case of the Diamond Coal & Coke Co., vs. the Baltimore & Ohio Ry. Co. *et al.* In this it holds that the rate on mining-car wheels from Rock Island, Ill., to Diamondville, Wyo., is unreasonable so far as it exceeds the rate on mining cars between the same points. The Commission says:

"Complainant contends that the commodity rate of 97½c. applicable on mining-car skips should also be applied on a part of the skip. The testimony shows that the wheels are an integral part of the skip and are subject to such rough usage in the mines that it is necessary to replace them several times before the body of the skip is worn out. Had these wheels been shipped with the bodies there would have been no question that the 97½c. rate was applicable. A shipment so made would not load nearly so heavily as a shipment of the wheels alone. The bodies of the skips are bulky and cannot be loaded to utilize all available car space. The wheels can be loaded compactly and require for transportation no equipment different from that provided for the bodies. Under the rate of 97½c. a particular car loaded with wheels would produce more revenue than one loaded with skip bodies or with the completed skip, including the wheels. Upon consideration of all the facts disclosed by our investigation, we are of opinion, and so find, that the rate assessed west of the Mississippi River for transportation of these car wheels was unreasonable so far as it exceeded the commodity rate of 97½c. applicable to mining-car skips."

Alabama

Birmingham—Announcement is made that a syndicate has been formed to underwrite the merger of the Alabama Consolidated Coal & Iron Co. and the Southern Iron & Steel Co. Harvey Fisk & Sons, of New York, are the managers. The new company will be known as the Alabama Consolidated Iron & Steel Co. and will issue $1,032,000 of 6 per cent. cumulative preferred, $4,130,000 common stock and $4.130,000 of 6 per cent. 20-year gold bonds.

The first battery of coke ovens at the Tennessee Coal, Iron & R.R. Co.'s new byproduct plant has been fired and the first coke turned out. The plant is being built at a cost of about $3,000,000 and in addition to producing coke and various byproducts will furnish gas power for a large electric plant that is to be erected in conjunction with it.

Arkansas

Denning—The coal tipple at mine No. 2 of the Western Coal Co. was destroyed by fire, Feb. 7. Two shot-firers were the only men in the mine at the time of the fire. They were quickly notified and escaped by climbing out the manway. About 300 men are thrown out of employment. The origin is unknown.

Colorado

Denver—Railroads engaged in coal traffic from southern Colorado to Oklahoma and Texas points, have been ordered by the Interstate Commerce Commission to establish joint rates and routes into these states from the Walsenburg district of Colorado within 90 days. This order was issued to enable Walsenburg coal shippers to compete on a fairer basis with the Canon City operators.

Illinois

Carlyle—The engine and boiler houses of the North Breese Coal & Mining Co., at Breese, were destroyed, Feb. 6, by a fire that was caused by an employee

dropping a lighted torch where waste and oils were stored. The flames spread instantly and soon were beyond control. Loss is $50,000, covered by insurance. The building will be rebuilt.

Medora—A 6-ft. vein of coal was recently discovered while drilling for oil on a farm in Shipman township. The seam was encountered at a depth of 180 ft. and is reported to be of excellent quality. The find was made at a point within a few hundred feet of the Chicago & Alton R.R.

Chicago—A proposed advance of 10c. in the minimum freight charge on small shipments to be made by all the railroads east of the Mississippi River and north of the Ohio was declared recently by the Interstate Commerce Commission to be without justification. An increase of 7c. a ton in the freight rate on bituminous coal from the fields in Williamson and Franklin Counties to Chicago was sustained by the commission.

Harrisburg—The annual convention of the Illinois Mine Workers will meet here, Mar. 10. The convention will urge that legislation be directed toward the provision of wash houses at all the mines.

The O'Gara Coal Co. has equipped a complete mine-rescue station, similar to those being established by the United States Government. The O'Gara company has 17 mines in the Harrisburg district, and the rescue station is centrally located so that any of the mines can be reached in a comparatively short time in the event of an accident.

Peoria—E. S. Barlow has decided to make every effort to pump the water out of his coal mine, near Kewanee. The mine was flooded recently, when an underground body of water found its way through the overlying strata, and caused operations to be suspended. A large pump has already been installed.

Indiana

Brazil—The Supine Coal Co., of Brazil, has leased 1000 acres of coal land near Center Point and is producing coal, clay and shale in large quantities. The work is being done with steam shovels and this method of operation is proving much more suitable and profitable than some previous attempts at mining in this section of the field. Similar operations are being carried on near Parkersburg and in other sections of Clay County. The miners are inclined to regard the advent of the steam shovel and stripping methods with considerable disfavor.

Indianapolis—It has been widely reported that certain business interests in this vicinity and in Illinois will petition Congress to intervene in order to prevent a suspension of mining at the expiration of the present wage-scale agreement. J. C. Kolsem, who presided at the recent joint conference of operators and miners, disclaims any knowledge of such a move being contemplated.

Kansas

Pittsburg—Employers of labor are slow in coming in under the provisions of the workmen's compensation act that went into effect Jan. 1. The act is not compulsory. So far only six coal companies have accepted its conditions.

Kentucky

Louisville—According to President Wheelright, the Elkhorn mines of the Consolidation Coal Co. will begin shipment early in the spring. Mining has already begun and the coal is being stored while awaiting the completion of the Sandy Valley & Elkhorn R.R. which is being built by the Baltimore & Ohio.

When the new branch of the Lexington & Eastern R.R., from Hazard to the coal fields east of Whitesburg, completes the tunnel just outside Hazard and two cuts, all the grade work will have been finished. One cut, near Boone Hill, will be finished in about 30 days, and the other, near Blackey, at about the same time. This causes the railroad officers to assert that the first train will be run into Whitesburg by May 1. The people of that section, as well as coal operators, are looking forward with much anticipation to the possibilities of the extension of a railroad to the center of Letcher County.

Barbourville—One of the most important announcements that has been made recently regarding Letcher County coal lands is that of the Lexington & Eastern authorities to the effect that a 5-mile spur line will at once be laid out, up Cholly Creek and that construction work will begin as soon as the weather permits. This spur will reach into a large territory, rich in coal and timber, and should greatly increase the traffic over the main line. The Currier Lumber Co., which owns a railroad terminating near the Kentucky-Virginia border, has announced that during the present year it will extend its line over into Kentucky and about six miles up the Pound River.

Michigan

Detroit—Reports from all over the state of Michigan indicate that the scarcity of coal is being severely felt. Large consumers in the Detroit district have appealed to the Interstate Commerce Commission to break the coal blockade at Toledo, Ohio. Through the inability of the Michigan railroads to receive cars consigned to them, the blockade reached an acute stage more than two weeks ago. Hampered by nearly 50 days of almost continuous zero weather, and by the heavy snowfalls that have prevailed throughout the northern portions of the state, the Michigan Central, the Pere Marquette, and other roads leading north from Toledo, have been confronted with the worst traffic situation in years. It is estimated that there are 8000 loaded cars on the tracks in Toledo, and on the sidings and storage tracks for a distance of 100 miles south of that point.

Ohio

Steubenville—Four hundred and fifty miners at the Bradley mine of the United States Coal Co. went on strike, Feb. 14, as the result of a dispute over pay for bottom coal and over the displacing of a miner who had been sick.

Four thousand acres of Pittsburg No. 8 coal in Munroe County, near Sunfish Creek, were recently sold for $190,000 by O. P. Markle and others, of Uniontown, Penn., who have large holdings in this district. There has been considerable activity of late in Monroe and Belmont County coal. The tract transferred by the Uniontown men is just south of the 21,000 acres recently sold to Toledo, Ohio, interests.

Columbus—The Imperial mine No. 1, at Derwent, in the Guernsey field, will have to abandon its slope entrance and construct a shaft instead, according to a ruling of the state mine inspector, backed up by the opinion of the attorney general. The laws of the state require that when the depth of a mine exceeds 100 ft., a slope shall not be used, and it is said the workings of the Imperial mine lie at a depth greater than this.

Announcement is now made of the completion of an agreement between the Chesapeake & Ohio and the Norfolk & Western R.R., that was stated as being under way last fall, whereby the Chesapeake & Ohio coal will be handled between Kenova, W. Va., and Columbus by the Norfolk & Western Ry.

It is stated that the coming conferences between the officials of the United Mine Workers and the operators of Ohio, western Pennsylvania, Indiana and Illinois, may be held at either Columbis or Cincinnati. When the joint conference at Indianapolis adjourned, some time ago, no place was fixed for the resumption of negotiations. Columbus is a central point in the field and the operators, in general, are said to desire to meet here.

Gallipolis—Representatives of an English syndicate have taken up the options on 8000 acres of coal lands in Perry and Greenfield townships, Gallia County. The same interests are behind the projected railroad from the Ohio River to Lake Erie, which will develop coal lands in Lawrence, Gallia and Meigs Counties.

Oregon

Marshfield— The announcement is made by H. B. Guthrey, president and general manager of the Pulaski Coal & Navigation Co., of Los Angeles, Calif., that his company has purchased the Pike coal property, on the Coquille River, three miles below Coquille. It is the intention of the new owners to develop the mine to its full capacity.

Pennsylvania

Bituminous

Myersdale—L. R. Brandenburg, of Baltimore, W. H. Clark, of Washington, and Col. Edward E. Robbins, of Philadelphia, representing a large eastern mining syndicate, were in Myersdale recently, making arrangements to take over the extensive coal holdings of the Hocking Coal Co., in Brothers Valley Township. It is understood that the new owners will at once proceed to develop the property and market the coal.

Monessen—Vesta No. 5 mine, at Fredericktown, which is claimed to be the largest bituminous mine in the world, recently began active operations. Although some little delay was experienced in getting the new machinery in order, everything is said to be working smoothly. No effort is being made for a "capacity" run and probably none will be made for some time. The officials will content themselves with a thorough trying out of the machinery before operations are begun on a large scale.

Pittsburg—Renewed activity in the coal industry of the Pittsburg district is shown by a report just issued by the Pittsburg-Buffalo company. This concern has recently given employment to 100 additional miners, and it is expected that 300 more will be given work at the company's mines in the near future. All previous records for coal production were broken at the Marianna mine, on Feb. 15.

Rockwood—The Keystone mines, at Casselman, have resumed operation, after being shut down since last July. It is understood that the tipple at the No. 1 mine will be abandoned before long and all the coal will be brought out and loaded at No. 2. Other improvements are also proposed.

Connellsville—A decision was recently handed down in the Westmoreland County courts which forbids coal-mining companies to polute domestic water supplies by draining into them the sulphur water from their mines. The decision was rendered in the case of James McCune against the Pittsburg & Baltimore Coal Co.

Ellwood City—W. C. and J. C. Cunningham, of Hazel Dell, have purchased the Wallace farm and coal mines west of Hazel Dell. They expect to begin operations at once.

Williamsport—The property of the Central Pennsylvania Coal Co. in Lycoming County consisting of about 1000 acres of coal land and improvements will be sold at public auction, March 8, to satisfy the claims of the Knickerbocker Trust Co. of New York.

Anthracite

Scranton—The great demand for coal on account of the continued cold weather kept the average wholesale price at tidewater at a high point during January. and the increase that will come to the mine workers as a result of the operation of the sliding scale will be 7 per cent.

The final hearing in the case of the Marian Coal Co. against the Lackawanna railroad is scheduled to take place Feb. 20 before the Interstate Commerce Commission in Washington. The outcome of the suit will determine whether or not the so called independents or individual operators shall continue to pay what many of them term extortionate rates for having their coal carried to tidewater by the big coal roads. If the commission decides that the rates are high, as is contended by the Marian company, it will result in a reduction not only on the Lackawanna, but on all the other railroads, for coal shipped from within the Scranton zone, which embraces that part of the anthracite region from Forest City to Shickshinny. Under the agreements with the big companies the individual operators get 65 per cent. of the price per ton that the coal roads get at tidewater.

Wilkes-Barre — Coal is being taken from the new Loomis colliery, at Nanticoke, by the Lackawanna railroad. The coal being mined at present, is taken from the Hillman vein, at a considerable depth and transported to the breaker of the Bliss colliery. A breaker will ultimately be built at the Loomis colliery but the plans are not yet completed.

Lansford—The Lehigh Coal & Navigation Co. has filed a bill in equity against the Central Railroad of New Jersey, asking for an accounting by the defendant for all sums expended in payment of rights of way and construction work done on the Lehigh & Susquehanna R.R., which was leased to the Central of New Jersey in 1871 by the Lehigh company. Bill alleges that the Central railroad has not lived up to the terms of the lease.

Utah

Ogden—The Black Hawk Coal Co. recently made its first shipment of coal. The mines have a daily capacity of 300 tons and within a few weeks it is anticipated that this will be increased to 1500 tons daily. The properties are located in Carbon County in southeastern Utah and embrace approximately 1200 acres, the coal vein being from 25 to 30 ft. in thickness. The mines are located on the Utah Southern railroad, about 14 miles southwest from Price and 157 miles from Ogden. Preliminary work commenced in February of last year and approximately half a million dollars has been invested in development work and for machinery.

Washington

Spokane—The Wilson Coal Co., of Centralia, Wash., has conveyed nearly one-fourth of its properties to a new company headed by George Dysart and known as the Sunshine Coal Co. The consideration was about $200,000. The Wilson Coal Co. still retains a large acreage of land on which there are extensive deposits of coal, but the company will not attempt to develop these lands at present, according to H. P. Wilson, secretary of the company.

The Tanum Coal Co., with property lying about 15 miles from Ellensburg, is planning to build a 1½ per cent. grade railroad from the mines to Thorpe, a distance of 7 miles. At this point connections can be made with both the Northern Pacific and the Milwaukee roads.

West Virginia

Wellsburg—It was decreed, Feb. 7, in the Circuit Court of Brooke County that the properties of the Wellsburg Coal Co. and the Wellsburg & State Line R.R. Co. must be sold to satisfy liens of contractors, material men and labor claims. The bond issues of the companies and all transactions pertaining thereto were declared fraudulent. The decree was made in the suits brought by contractors and others in 1905 after the railroad had abandoned its right of way, the coal tipples and other improvements at the coal properties it had planned to develop. The coal company had title to many thousand acres of coal and the railroad owned a right of way through rich farming country. More than $1,000,000 is said to have been involved in the suits.

Great Britain

London—The acuteness of the crisis in the British coal trade is emphasized by the prohibitive rate of 94½ per cent. asked by Lloyds on insurances against a national strike. It is reported that 800,000 miners have already handed in their notices to quit work Feb. 29. The Federation of National Transport Workers has pledged itself not to handle "blackleg" coal, so that imported coal will be landed with great difficulty. The government announces that it will take the crisis in hand although there is as yet no indication of how it proposes to attempt to break the deadlock.

The two-day conference between mine owners and representatives of the miners ended Feb. 20, without reaching an agreement. The British Admiralty has chartered two vessels to carry 10,000 tons of American coal to Gibraltar.

Personals

H. McKean Conner, of Beckley, W. Va., has been appointed superintendent of the Tennessee Coal, Iron & R.R. Co.'s Pratt No. 12 mine, near Ensley, Ala., effective Mar. 1, 1912.

C. V. Westover has resigned as superintendent of the Ludlow mine of the Huerfano Coal Co., Ludlow, Colo., to take a similar position with the Cambria Fuel Co., at Cambria, Wyoming.

C. W. Saxman, formerly mechanical engineer with the Latrobe-Connellsville Coal & Coke Co., Latrobe, Penn., has resigned to take the position of general manager of the Copper Reef Consolidated Mining Co., Globe, Arizona.

Duncan Medill has sold his interest in the Rutland Coal Co., Rutland, Ill., and resigned his position as manager of the Rutland mine to become general superintendent of the five mines near Clinton, Ind., that are owned by John Deering, of Chicago.

John W. Skeele, formerly vice-president in charge of sales of the Lehigh Valley Coal Co., has been elected president of the newly organized Lehigh Valley Coal Sales Co., which has been incorporated with a capital of $10,000,000, to take over and market the production of the Lehigh Valley Coal Co. George N. Wilson was elected vice-president and secretary of the new company, and William J. Burton, treasurer.

Dr. M. J. Shields, of the American Red Cross, intends to devote his almost entire attention to railroad first aid, in the next few months. He will visit Du Bois and Punxsutawney, and at these places and in the vicinity, he will lecture to and organize first-aid bodies among the miners. He will attend with his car the International Congress of the Red Cross Societies, meeting at Washington, D. C., between May 7 and 17, and will preside at a contest to be arranged between teams of miners, policemen, firemen, railroad men and steel workers.

James Needham, assistant general manager of the Union Pacific Coal Co., has resigned to become general manager of the coal properties of the Chicago, Milwaukee & St. Paul R.R. Co., with future headquarters probably in Chicago. Mr. Needham's appointment fills a vacancy occasioned by the recent death of W. W. Taylor, president of the St. Paul Coal Co. The duties of the position formerly occupied by Mr. Needham with the Union Pacific Coal Co. have now been divided. W. D. Brennan, superintendent of the Superior mines, becomes general superintendent of the Superior Coal Co., in addition to his former duties, and George Pride, superintendent of the Union Pacific mines at Rock Springs, Wyo., becomes assistant general manager of that company.

Obituary

George Canbee Clark, president of the Horace Clark & Sons Co., and president of the Clark Coal & Coke Co., died at his home in Peoria, Ill., Feb. 5, aged 65 years.

S. D. Conover, aged 68, died at his home in Dayton, Ohio, Feb. 8. Mr. Conover had been identified with the coal business in Dayton for a great number of years and was one of the city's most prominent business men.

Francis B. Stillman, president of the Watson-Stillman Co., manufacturers of hydraulic machinery, died recently at his home in Brooklyn, N. Y. Mr. Stillman was in his sixty-second year. He was a graduate of Yale in the class of 1874, a member of the Engineer's Club and of the American Society of Mechanical Engineers.

Construction News

Wilton, N. D. — Improvements are planned for the plant of the Washburn Lignite Coal Co., to be made during the coming summer.

Bethany, Mo.—The Cainsville Coal Mining Co. has recently given a mortgage for $250,000 to secure bonds issued to improve the properties at Cainsville.

Cumberland, Md.—The Georges Creek Coal Co. is planning to open up three additional mines on its property at Lonaconing, Md. Mr. Coale is general manager.

Barbourville, Ky.—The Edgewood Consolidated Coal Co. has resumed operations, and will equip a coal-washing plant in addition to installing other machinery.

Hooversville, Penn.—Plans are being prepared for the erection of a large tipple at Mine No. 1 of the Knickerbocker Coal Co. Construction is expected to begin in the early spring.

Pikeville, Ky.—C. H. Gorley, treasurer of the Marrowbone Coal & Coke Co., has announced that the company will rebuild the tipple, elevator, etc., that were recently destroyed by fire, as soon as insurance adjustments are made.

Milwaukee, Wis.—The Kanawha Fuel Co. has purchased 1800 ft. of dock front and will at once improve the property. Total expenditures are expected to reach about $500,000. Three new coal-handling bridges will be installed, as well as other machinery and buildings. A. S. Austin is president.

Duluth, Minn.—The Berwind Fuel Co. will build a large dock and coal-storage plant on the property in West Duluth recently purchased at a cost of $150,000. The plant will have a capacity of about 1,000,000 tons and will be equipped with modern hoisting rigs and coal-handling machinery. It is understood that in all, four large docks will be built or remodeled this year at the head of the Lakes.

Bristol, Va.—In connection with its recently announced contract to furnish a large amount of coal to New England railways, the Virginia Iron, Coal & Coke Co., of Toms Creek, expects to double its output at the Banner operation, and to do this will install additional machinery, including a number of electric motors.

New Publications

NAJPIERWSZEJ POMOCY. P. Blakiston's Son & Co., Philadelphia. 186 pp., 4x6 in.; 49 illustrations.

This book, of which the title is abridged above, is a translation into the Polish language, of the well known "American Red Cross Abridged Text Book on First Aid," by Charles Lynch and M. J. Shields, the leaders of industrial work in the American Red Cross Society. It has already been published in English, Slovak and Italian. The Lithuanian edition will soon follow.

THIRTEENTH ANNUAL COAL REPORT FOR ILLINOIS. Martin Bolt, chief clerk, Springfield, Ill. 445 pp., 6x9 in., illustrated.

This report presents with commendable thoroughness and clarity, the statistics of the coal-mining industry in Illinois for the year ending June 30, 1911. By far the greater part of the information contained in the volume is in tabulated form, and figures for previous years are given for comparison. Notes and descriptive matter are condensed and concise.

COALS AVAILABLE FOR THE MANUFACTURE OF ILLUMINATING GAS. By A. H. White and Perry Barker, compiled and revised by Herbert M. Wilson. Bulletin No. 6, U. S. Bureau of Mines. 76 pp., 6x9 in.; 4 plates, 12 illustrations.

The experiments recorded in this bulletin are dedicated largely to the proposition that since the well known gas coals of western Pennsylvania are rapidly becoming exhausted and their cost is becoming relatively high, it behooves the investigator to determine whether or not coals from other regions may not be successfully utilized in the manufacture of illuminating gas, gas coke and the various attendant byproducts.

The authors present the results that were obtained, largely without comment or inference, and state that they are to be taken as tentative and suggestive rather than as indicating conclusions in any way final. Nevertheless it is evident that not a few of the coals tested give such promise as to abundantly warrant further and more thorough investigation. Eighteen tests on 11 different coals from 10 states are reported.

Trade Catalogs

Electric Weighing Co., 180 Thirteenth Ave., New York. Pamphlet. Electric weigher for ore, coal, cement, etc. Illustrated, 16 pages, 6x9 inches.

The Hirst-Butler Electrical Machine Co., Inc., Reynoldsville, Penn. Catalog. "Little Giant" direct-connected rotary electric mining machine. Illustrated, 4x8 inches.

Best Manufacturing Co., Pittsburg, Penn. Catalog No. 103. 395 pp., 4¼x6¾ in.; illustrated. Catalog covers the complete line of material and supplies manufactured by the Best company and also additional material not manufactured by this company but usually a part of power-plant equipment. A few pages of general engineering information are included.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

While consumption has eased off considerably, in response to the warmer weather, the congestion in transportation continues unrelieved and the movement of freight is slow. Both men and equipment in the railroad service appear to have been severely overtaxed during the cold weather, and it is believed that some time will elapse before conditions are normal.

The situation at the Atlantic Coast ports continues acute, some schools and other public buildings being closed because of the lack of fuel; the movement, both rail and water has been slow, but the warmer weather promises to lift the ice embargo on water shipments. Pittsburg reports the market stronger with prices 5 to 10c. higher and mines working 80 to 90 per cent. capacity, depending on the car supply.

Transportation in the Ohio fields is still demoralized and the demand continues heavy with prices strong; the car supply is the predominating feature in Ohio. The president of the largest operating company in West Virginia states that trade conditions are now more encouraging in that state than at any time during the past two years. Bunker trade has been good at tidewater, coal scarce generally and prices firm.

In the Middle West the situation is improving and the past week has witnessed a satisfactory output at the mines and a heavy movement, particularly into Chicago. While the demand has slacked off at some points, due to the milder weather, all free coal is being readily absorbed for storage purposes; the railroads in particular are storing heavy tonnages. The market in the far West continues dull and unchanged.

Boston, Mass.

Mild weather is some relief to the distressing situation that has prevailed here for some weeks. It at least reduces consumption, and if it continues, will raise the ice embargo at a number of points. The ice in Vineyard and Nantucket Sounds has for the most part disappeared, and movement by water is that much improved. The shortage of coal, however, is most acute, and there is apprehension of trouble all along the line. It will take a long time under the best of conditions to recover from the effect of the last seven weeks of unparalleled cold weather.

Anthracite receipts are few and far between. The smaller producing companies seem practically to have gone out of business so far as concerns this market. The larger shippers have been declining orders for some weeks.

In bituminous the only change from a week ago is to higher prices for what little spot coal is available. The freight market is firm at high figures, and there is some bidding up of rates from New York to sound ports, in the anxiety to get entered for coal. All-rail delivery is the slowest yet. On one end of the roads there are upward of 20,000 cars hung up in transit, largely on account of the lack of motive power. Prices for coal at the transfer points are, therefore, on a premium basis. Car shortage is bound to be marked for weeks to come.

Water freights are strong at $1.25, Hampton Roads to Boston, $1.15 to Providence, on the largest bottoms. On barges from New York to Providence and other sound ports, $1.15 is asked.

Prices are as follows:

Clearfield, f.o.b. mines	$1.35@1.60
Somerset County, f.o.b. mines	1.40@1.60
Pocahontas, New River, Boston, Portland, on cars	4.75@5.00
Pocahontas, New River, Providence, on cars	4.50@4.75
Pocahontas, New River, f.o.b. Virginia terminals, for spot shipment	2.85@3.00

New York

Although the weather has shown some moderation, the soft-coal market continues quite firm. There has been no increase in the standing tonnage at New York loading piers and the amount of coal on hand is far below that usually carried. Demand on contract is extremely heavy and shippers are having all they can do to satisfy the requirements of their contracts.

There is some spot inquiry but considering the shortness of the supply in this market, prices have not shown the advance that would be expected under the conditions. The demand for the standard grades of steam coal is so heavy on contract that these coals are all out of the market and about the only coals now obtainable here are the ordinary grades of Pennsylvania and West Virginia steam. These are being quoted on basis of from $2.70 to $2.80 f.o.b. New York piers, which is an advance of about 10c. a ton over what these coals were being offered at last week.

Consumers generally are alive to the possibilities of a strike in the bituminous and anthracite fields the first of April and much anxiety is being shown among them to accumulate stocks for use in the event of such an emergency, but with the short car supply, slow traffic conditions and the general shortage of coal, most of them are meeting with but little success, as the companies are having all they can do to furnish contractors' coal for their actual requirements.

Philadelphia, Penn.

The retail trade in this locality still reports active business conditions. While the week started in with a thaw, this in a measure only helped deliveries, while the house holders are still insistent that their orders be filled promptly. The open weather will also have the effect of improving the deliveries of the railroads, which have been much hampered by the low temperature. The continued mild weather, however, is likely to affect the receipt of new business, although the rumors of trouble at the mines, and reports of shortage of stocks in the hands of the large operators, make every dealer anxious to keep his yard filled, and this same feeling is passed along to the consumer. No size is reported in good supply as yet, orders being filled by the wholesalers from a week to ten days after receipt. The market at this time is likely to be little affected by the weather conditions.

The wholesale dealers still continue to be deluged with orders far in excess of their ability to fill promptly. One large operator states that they are from one to two weeks behind on their orders, and constant receipt of new business gives no opportunity for the placing of any coal in stock. As it looks now, March is likely to be a busy month. February tonnage to date is far in excess of the same period for last year, and little coal will go into the storage yards from now until the first of April.

Pittsburg

Bituminous—Nothing has been accomplished yet by the joint committee appointed before the close of the Indianapolis convention to discuss the wage scale. The coal market has firmed up by 5c. to 10c. per ton. Coal is in excellent demand, partly on account of interruptions to service through the continued cold weather and partly for stocking up purposes in anticipation of a suspension of mining Mar. 31. There has been a

distinct shortage of cars during the past fortnight, and conditions are no better this week. As a rule, mines are operating as full as the car supply will permit, and operations on the whole are at 80 to 90 per cent. of capacity.

Quotations may be regarded as on the basis of $1.15@1.25 for mine-run, as against $1.10@1.15 formerly quoted, previous differentials maintaining, and we now quote as follows: Nut, $1.10@1.20; mine-run, $1.15@1.25; ¾-in., $1.25@1.35; 1¼-in., $1.40@1.50; slack, 90c.@$1 per ton at mine, Pittsburg district.

Connellsville Coke—The market for prompt coke has stiffened up a trifle in the past three or four days, and it is difficult to get the minimum quotations formerly made. Sales of scattering lots of prompt furnace coke have been made in the past week to the extent of 50 to 75 cars, at $1.85, while on Friday one lot of 12,000 tons was sold in the East at this same figure, delivery within a month.

There has been no important negotiating for coke on contract. We continue to quote: Prompt furnace, $1.80@1.90; contract furnace, $1.80@1.90; prompt foundry, $2.20@2.30; contract foundry, $2.20@2.40 per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ended Feb. 10 at 354,569 tons, a decrease of 5000 tons, and shipments at 3999 cars to Pittsburg, 5679 cars to points West and 912 cars to points East, a total of 10,590 cars, a decrease of 33 cars.

Baltimore, Md.

It was thought here that the rather mild weather experienced about the middle of the week would help conditions materially. Contrary to expectations it did not, and operators report that they are having as much trouble procuring the necessary equipment as they did earlier in the week, or even during the period of zero weather.

The Western Maryland has experienced all sorts of trouble in moving coal traffic during the past few days and conditions have not been much better on the Baltimore & Ohio, although the management of both roads are doing everything within their power to improve conditions.

The coke market, according to reliable reports from the trade, continues strong. The market is showing greater improvement than has been noticed for nearly a year.

Buffalo, N. Y.

It is generally impossible to get a quick delivery from most of the railroads and some of them are doing next to nothing. The weather has turned mild now, but the cars are not moving and probably will not move at all briskly for some time, as the motive power was overtaxed by the weather and the men are badly used up from cold and overwork.

There is a disposition on the part of the coal consumer to stock up now against a possible strike in April, but the shipper cannot furnish the coal. The mine output is less than it was before the cold weather set in and now there begins to be complaint that the empty cars are not coming back promptly, for the reason that they have not been taken to destination and unloaded.

Prices are nominally as before, though the premium is sometimes liberal when coal is to be had on the spot. Pittsburg quotations are $2.60 for three-quarter, $2.50 for mine-run and $2.25 for slack, with Allegheny Valley about 30c. less. Coke remains strong at $4.25 for best Connellsville foundry and $3.50 for stock.

Anthracite shippers are but a short time, some say three weeks, ahead of the consumers, though this is hard to calculate. As a rule, the retail dealer has no coal at all and the consumer has only a small supply. The only reassuring feature of this trade is that the operators announce that they are not going to advance their prices. Independent anthracite is bringing a good premium where it can be had and delivered to customers.

Cleveland, Ohio

The break in the weather this week does not seem to lessen the demand for coal. The temperature has been in the neighborhood of 34 deg. for the past two days. While the prices in the Cleveland market continue strong, the chief factor in the situation is the car supply. The railroads and larger corporations have all doubled their orders in anticipation of a strike.

Smokeless coal is variable in price, but in strong demand, and what little there is of spot smokeless, commands a price of $1.15@1.25 for mine-run.

Prices range as follows:

Cambridge	
Mine-run	$1.15
¾-in	1.25
Slack	$0.90@0.95
Ohio No. 8	
Mine-run	$1.10
¾-in	1.20
Slack	$0.85@0.90
Ohio No. 6	
Mine-run	$1.25
¾-in.	1.35
Slack	$1.00@1.05

Columbus, Ohio

Demoralization still continues on all railroad lines leading from the Ohio coal fields, and as a result the trade is in a chaotic condition. Congestion of way points and connecting lines has made it almost impossible to move much coal and reports show there is considerable suffering in Michigan and northern Indiana points. It is not the fault of the operator who is ready and willing to ship the coal if the railroads could move the cars and return the empties to the mines promptly.

As a result of these conditions prices have been ruling firm on all grades and varieties. Premiums are being paid for spot coal ranging from 10 to 25c. There is a good demand for fine coal and prices are firm.

Reports show that in many points in Michigan factories were compelled to shut down to permit the small supply of coal to be used for domestic purposes; little of this was necessary in the State of Ohio.

Production in Ohio fields was considerably curtailed because of the car shortage and railroad congestion. Many of the mines were closed down almost entirely and others only ran a portion of the time. The reports show that the output was between 35 and 50 per cent. of normal, and in some fields the percentage was even lower. The operators were willing and ready to produce a much larger tonnage, but railroad facilities were such as to make this impossible.

Retail trade has been rather active as stocks in the hands of consumers had to be replenished. Prices have reached the usual winter level.

Prices prevailing in Ohio are:

Domestic lump in Pomeroy Bend district	$1.85
Domestic lump in the Hocking Valley	$1.60@1.75
Three-quarter inch	1.45
Nut	1.20
Mine-run in eastern Ohio	1.05@1.10
Mine-run in the Hocking Valley	1.15@1.20
Nut, pea and slack	0.80@0.90
Coarse slack	0.70@0.80

Cincinnati, Ohio

Because of unusual market conditions, all persons connected with the coal trade are trying to figure some way out of the difficulty, due to inadequate transportation facilities, if not management, on the part of the railroads. Lack of equipment possibly is the real cause at the bottom of the trouble.

Most of the railroads have issued embargoes against further transportation of coal to the congested points, in the hope that they will thus be enabled to clear the yards now filled with cars of fuel. It is said that in Toledo alone there are 12,000 cars of coal awaiting delivery. Other northern points, particularly in Michigan, are said to be in much the same fix. The railroad yards in this immediate market are also well filled with cars, although it is said the railroads have adopted a policy of keeping the congestion from the largest cities as much as possible, because of the clamor that would be raised by the coal men in demanding that their cars be moved. With the cars at a more distant point, they cannot so readily ascertain just what the conditions are and cannot make their demand so concrete.

Prices now being quoted for the various grades are as follows: Smokeless lump, $2.15@2.25; smokeless mine-run, $1@1.25; splint lump, $1.10@1.95, according to the wide range of quality en-

tering this market; splint mine-run, $1.10@1.25; splint nut and slack, 65 to 95 cents.

The quotation on smokeless mine-run is almost entirely a speculative one, since it is impossible to buy that fuel and next to impossible to get the nut and slack. Wholesalers are refusing to accept any orders and are begging each other for the accommodation of a car or two to fill their contracts. Even by helping each other out as far as possible, they are having great difficulty, and sometimes are unable to meet their own requirements.

Charleston, W. Va.

Demand for coal is strong, but the car supply is holding a strong check on supplies. Prices likewise are strong and a fair increase is reported in many instances. These conditions prevail in both the Kanawha and New River districts, and while there has been a slight improvement in the car situation, it has been very slight. At the present time the mines are only operated about three days a week, which is an indication that the car supply is only half that which the mines could utilize, providing, of course, the demand was sufficient to operate at capacity.

Prices in the Kanawha and New River districts are reported as follows:

Kanawha	
Mine-run	$0.85@0.90
Slack	0.65@0.70
Lump	1.40@1.60
New River	
Mine-run	$1.15@1.25
Egg	1.60@1.80

Hampton Roads, Va.

Coal is still scarce at Hampton Roads ports and prices are firmer; none of the standard grades of New River and Pocahontas are being sold at less than $2.70 f.o.b., while some sales of nut and slack have been made on a basis of $1 f.o.b. mines. There are still, of course, considerable amounts of low-price contract coal being shipped to New England, and the U. S. Navy has been taking more coal than usual.

Bunker business has been exceptionally good and several cargoes have been loaded for the West Indies, but the European export trade has been seriously held back by the high steamship rates, the rate to Buenos Aires and La Plata being quoted at $6.72 and to Genoa or West Italy, $4.08 to $4.32.

The movement of coal from the mines has been slow on the Chesapeake & Ohio and the Virginian Railways; the Norfolk & Western has been giving good movement, but the car supply on all roads has been extremely bad.

Dumping has also been slow, owing to the frozen condition of the coal in cars. After the railroads get over the effect of the cold weather, there should be some record-breaking shipments, as the demand for coal is strong and seems likely to continue so. From all accounts stocks of coal in New England are low and all contractors are being pressed for coal, which demands they are most anxious to fill, in order to get rid of all their low priced business and to be in a position to take advantage of the better prices.

Louisville, Ky.

Due to the car shortage primarily, the price of coal in the mining regions of the southeastern part of the state has been shoved up to a point not equalled for two or three years. Outside of the fact that lack of equipment prevented the shipment of coal in quantities equal to the demand, the miners of that section have had an unusually prosperous year. The operators in the southeastern section have built up an excellent market in the North, which is expected to grow steadily. The increased railroad facilities being provided and the installation of selling agencies in the North has resulted in the Kentucky mines competing with the West Virginia output more successfully than has been expected.

Indianapolis

There has been an active week in coal mining with a satisfactory output, and the demand has kept up, notwithstanding the moderate weather. A number of mines throughout the state are advertising for miners, and full time in most all the mines is being worked. Whether preparation is being made for a cessation of mining after Apr. 1 is not positively known, although there are some evidences of it.

The Indiana mines are now being operated at nearly full capacity and that means a large output. Miners' wages are totaling more than at any time for 14 months.

There has been no increase in the price of coal nor is there likely to be unless a cessation of mining shall afford an excuse for same.

Nashville, Tenn.

Business still continues brisk in the west Kentucky coal field, even though the weather is back to normal.

The scarcity of cars is still in existence and all operators are far behind with their deliveries. The month of March will be a good one in view of the fact that the first of the month will catch the cities with practically no coal and there will be a certain tendency to do some stocking locally; there has also been, in the last few days, a number of foreign inquiries, most of which, however, are for outright purchases, commencing Apr. 1.

The demand for screenings is still large and good prices are being offered; in fact, prices will continue good from now until Apr. 1. Operators in this district are awaiting with great anxiety the result of future meetings and conferences between the operators and miners in the union fields.

Chicago

A general tendency to buy for storage against the possibility of a strike and the unusual export movement are the chief features of a steady market which has upward tendencies in several respects.

As a result of a scarcity of cars in southern Illinois only a small volume of washed coal was shipped to this market and as an outcome there has been a heavy demand for nut coal. The latter had previously occupied a weak position in the market. There has been a big demand and a small supply of smokeless and mine-run is sold at $1.25 to $1.35.

The market for screenings has been steady although the great bulk of the buying has been done by the smaller interests. Heavy orders are being received for anthracite, but the shippers have been able to satisfy the demands. There is a keen demand for coke; gas house is scarce and strong.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.87
Egg	2.87
Steam lump	$2.37@2.57
Screenings	1.97@2.07
Springfield:	
Domestic lump	$2.67@2.82
Steam lump	2.32@2.42
Mine-run	2.12@2.22
Screenings	1.92@2.03
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.22@2.32
Mine-run	2.17@2.27
Screenings	1.87@2.00
Pocahontas and New River:	
Mine-run	$3.25@3.55
Lump and egg	4.20@4.30

Coke—Prices asked for coke are; Connellsville and Wise County, $4.65@4.75; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $4.90@5.

Minneapolis—St. Paul

The retail coal business in the Twin Cities has dropped off considerably in the last three days due to the mild weather. The wholesale men are only doing a fair business because the dealer in the country is not ordering freely, as he has some coal that was ordered during the cold weather and which is now coming in.

The car situation is not exactly what it should be as there still seems to be a shortage at the mines and the docks. However, the railroads deserve a lot of credit in their attitude of trying to overcome this shortage and coal men believe they have done everything in their power to prevent the usual coal famine which has prevailed in the Northwest nearly every winter.

Dockmen say the supply of anthracite coal in all sizes is low at the docks and the opening of navigation will find the docks practically clean. Prices on dock and all-rail coal for shipment into the country are strong. Franklin and Carterville County coals are selling for $2 and up to $2.50 and the other grades of Illinois coal are selling for $1.75 up. A lot of the coal coming into the Twin Cities now is on contract.

St. Louis, Mo.

The latter part of last week brought a slump in the market on all coals, and the weather the beginning of the present week was anything but favorable to the market. The only thing that keeps the market in fair condition at the present time is the fact that the railroads are buying heavily from all fields, and that steam plants have started to stock up to some extent. The car shortage is also a factor in keeping the prices up, as the mines on the Illinois Central are working but one day a week; the Iron Mountain mines get about four days a week and the C. & E. I. from four to five.

In the Standard field the market seems to be dropping, with indications that it will perhaps be better the latter part of the present week. There is an excellent demand for screenings, but the other sizes seem to be off, and indications are that the screenings market will continue to get better, while the market on the screened sizes for the greater part of the coals will remain about as it is.

There is a good demand for anthracite, or there has been, but failure to deliver has caused many cancellations. Coke is in good demand at prices that have remained steady for the past two weeks. Smokeless is moving freely, with a good demand, and the high grade coals from the Standard field are holding their own at from $2 to $2.25 at the mines.

The prevailing prices the beginning of the week were as follows:

Franklin County	
Lump and egg	$1.85@2.00
No. 1 nut	1.75@1.85
No. 2 nut	1.50@1.65
No. 3 nut	1.25@1.35
2-in. screenings	1.00@1.10
Carterville	
Lump and egg	$1.75@1.85
No. 1 nut	1.50@1.60
No. 2 nut	1.35@1.45
No. 3 nut	1.20@1.30
Screenings	0.90@1.00
Mine-run	1.20@1.25
No. 1 washed	1.75
No. 2 washed	1.60
No. 3 washed	1.50
No. 4 washed	1.25
No. 5 washed	0.75
Standard	
6-in. lump	$1.50@1.60
2-in. lump	1.25@1.40
3x6-in. egg	1.15@1.25
No. 1 nut	1.10@1.15
No. 2 nut	1.00@1.05
Screenings	0.80@0.85
Mt. Olive	
6-in. lump	$1.50
2x6-in. egg	1.25
No. 1 nut	1.15
No. 2 nut	1.05

Spokane, Wash.

The prices of coal in this territory remain the same, with no changes expected in the near future. Local dealers are well stocked and the demand is not heavy. Warm weather is prevailing, the temperature ranging from 35 to 50 deg. and no more cold weather is expected.

Portland, Ore.

There is little change in the situation here as far as the coal market is concerned. The weather is mild and spring is rapidly approaching. This has been a mild winter all through the state and the demand for lumber has been lighter than any average previous year.

Prices remain unchanged and fluctuated little during the winter, the only increase being the usual $1 at the opening of fall known as the storage charge. Half of this charge was removed in January when it was noticed that the demand for fuel would be light for the remainder of the winter.

Production and Transportation Statistics

Norfolk & Western Ry. Co.

Comparative statement of coal and coke shipments over the lines of the N. & W. Ry. Co. for January, 1911-12, was as follows, in short tons:

Destination	1912	1911
Coal		
Tidewater, foreign	79,646	112,204
Tidewater, coastwise	204,623	248,219
Domestic	1,261,686	1,327,525
Coke		
Tidewater, foreign	12,347	4,556
Domestic	146,954	127,084
Totals	1,705,256	1,819,588

The following is a statement of commercial and company coal from mines on the Norfolk & Western Railway for January in short tons:

Field	Commercial	Company
Pocahontas	1,014,810	95,599
Tug River	131,984	35,314
Thacker	165,179	49,523
Kenova	67,526	10,070
Clinch Valley	107,966	9,977
Total	1,487,465	200,483

Foreign Markets

Great Britain

The labor situation having taken a more serious turn, many sellers are seeking higher figures for forward loading, but without finding buyers. Quiet conditions rule on the coal market today. Quotations are approximately as follows:

Best Welsh steam coal	$4.56@4.62
Seconds	4.38
Thirds	4.08
Best dry coals	4.50@4.62
Best Monmouthshire	4.20@4.26
Seconds	3.96@4.02
Best Cardiff small coals	2.78
Seconds	2.58

The above prices for Cardiff coals are all f.o.b. Cardiff, Penarth or Barry, while those of Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage and for cash in 30 days, less 2½% discount.

The following is a comparative statement of the British exports for January, 1911-12:

	1911	1912
Coal	4,956,215	5,421,175
Coke	100,017	113,871
Briquetts	166,709	148,932
Bunker coal	1,564,738	1,516,659
Total	6,787,679	7,200,637

German Empire

Fuel production of the German Empire for the years 1910 and 1911 was as follows, in metric tons:

	1911	1910
Coal	160,742,272	152,881,509
Lignite	73,516,789	69,104,867
Coke	25,405,108	23,600,362
Coal briquettes	4,990,988	4,441,239
Lignite briquettes	16,836,679	15,125,777

Financial Notes

It is expected the Lehigh Valley Coal Sales Co. will formally engage in business, Mar. 1.

Board of directors, American Coal Co. (New Jersey), have declared the regular semiannual dividend of 3% payable Mar. 1, to stock of record Feb. 29.

Eleven first-mortgage, 5%, 50-year gold bonds of the O'Gara Coal Co., dated Sept. 1, 1905, for payment at 105 and interest, are called for Mar. 1.

In the organization of the Alabama Consolidated Iron & Steel Co. there will issue: $4,130,000 6% 20-year mortgage bonds, $1,032,500 6% cumulative preferred and $4,130,000 common, for which the syndicate will pay $4,130,000 less commissions. Both classes of stock will be represented by voting trust certificates. Alabama preferred stockholders will be assessed $60 a share and will receive in exchange $60 in bonds, $15 new preferred and $60 new common. Common holders upon paying $50 assessment will receive $50 bonds, $12.50 preferred and $50 common. Southern Iron & Steel preferred holders must pay $20 cash in order to receive $20 bonds, $5 preferred and $20 common in new company. The Southern common holders will be assessed $10 and will receive $10 each in bonds and common and $2.50 of the new company's preferred.

For the 12 months ended Dec. 31 last it is understood that Island Creek Coal Co. earned a balance for its 100,000 shares of common of slightly better than $2.25 per share after making liberal charges for depreciation and after meeting the $6 dividend on the 50,000 shares of preferred. The company, had it so elected, could have shown a common dividend balance of $3 per share or better. Conditions have been rapidly mending and the last four months of 1911 showed net earnings at the rate of better than $4 per share. It is expected that 1912 will show an output 35% greater than last year with more than a corresponding increase in net due to better prices. By 1913 it is the expectation of the management that production will very nearly touch the 3,000,000 ton mark. Island Creek is already the third or fourth largest coal property in West Virginia.

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—An electrician for a coal mine in southwest Virginia; must be able to wind armatures, understand mining machines and be able to look after steam and electric plant; in answering state fully experience and salary expected. Va-Lee Company, St. Charles, Va. Feb. 24.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Position wanted as manager or general superintendent; twenty-eight years' experience in mining, and have filled positions from door boy to general superintendent; I am a graduate mining engineer, familiar with every detail in producing, washing and coking coal, including costs and accounts; married and temperate in habits; references furnished. Address Box 6, care Coal Age.

Wanted—Position—First class electrician and mechanic; expert on all types of armatures, winding, building power plants, construction work, remodeling mines, locomotives, fans, pumps, coal cutter; best of credentials as to integrity and ability. Address Box 12, Coal Age. Feb. 24.

Uptodate engineer, over 30 years' experience in bituminous mining, will accept position as engineer or superintendent for a coal company; am at present employed, but desire a change; I am married; abstainer of liquor. Address Box 13, Coal Age. Mar. 2.

Pneumelectric

TRADE MARK

THE ELECTRICALLY OPERATED COAL PUNCHER

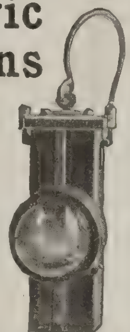
Others are using it to increase their profits

WHY NOT YOU?

Let us tell you about it.

The Pneumelectric Machine Company Syracuse, N. Y.

Hubbell Electric Safety Lanterns



Ideal for MINE Use

For general use about the mine, the officials' and Miners' Hand Lantern here shown is unequalled. It is excellently adapted for work in tunnel headings, for use with rescue apparatus or coal punching machines. Cost of operation is only about half that of any oil lamp. *Write for catalog.*

PORTABLE ELECTRIC SAFETY LIGHT CO.

14 Johnson Street, Newark, N. J.

The Mine Lamp with Lowest Operating Cost

A Mine Lamp that supplies an 18 candle power light, for 10 hours, on 6 oz. of carbide (cost, 1½ cents).

The Scranton Acetylene Mine Lamp

Has the most practical Water Control Valve of any mine lamp made. Absolutely free from grease, soot and smoke. Built for rough service, giving powerful, steady light for all kinds of work.

Price, complete. $1.00.

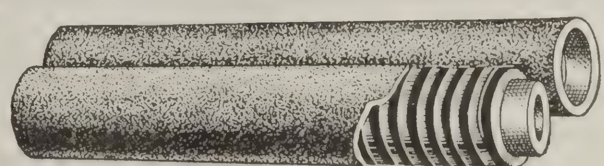
Write for Catalog.

Scranton Acetylene Lamp Company

145 Belmont Terrace, Scranton, Pa.

For Sale

A mining property and brick plant located at Ralston, Lycoming County, Pa., on the Northern Central Railway. The brick plant is complete and has a capacity of 20,000 per day. The coal property consists of about 3,000 acres of land, of which about 500 acres are underlaid with a vein of bituminous coal and shale of excellent quality for making brick. The mines are developed and in working order with a complete electric equipment; capacity 350 tons per day. Besides the power-house and other necessary buildings, there are, on the property, a church, school-house and over 70 dwellings. The two plants can be worked together economically. For particulars inquire of IRVING ELTING, President, Poughkeepsie, N. Y. or Jno. D. Allison, Sec'y and Gen'l Manager, Roaring Branch, Pa.



Acid Water Does Not Affect It

Destructive mine waters have no affect on machine made wood water pipes. The steel hooping gives the necessary tensile strength and the asphaltum covering resists acids of mine water.

Our facilities allow us to quote low prices and make prompt shipments. Send for a Catalog.

Eastern Manufacturing Co., Elmira, N. Y., U.S.A.

Save Armature Repairs!

Hess-Bright Ball Bearings save *wear* by saving *friction*. They run for years without attention of any sort, save to repack with grease every two months. Used by leading builders of mine locomotives, and may be applied to existing equipment.

Moments with the Advertising Editor

A Department for Subscribers Conducted by the Service Department of Coal Age

No advertiser would hire Ananias to write his copy these days.

The time of deception is past—and the reason why the ads you read "ring true" is simply because there's sincerity back of them.

Advertising is not a gamble any more—it's a sound business investment. And the concern that O. K.'s an ad stakes its reputation on the contents of the ad.

Truly, the world do move.

* * *

Here's another way of looking at it. A concern's advertisement is an invitation to you to trade with them. And when a concern fails to advertise, their attitude may well be looked upon as a sign that they do not care enough about securing your business to even ask for it.

* * *

Advertising is a black art only in this way—it's the art of putting honest propositions before you through the medium of black ink. The only devil behind an advertisement is the Printer's Devil.

* * *

It's the reader of advertisements—not the manufacturer—who has made advertising what it is today. For the reader has shown that he wanted to be told about products that would help him in his work or his play.

He has shown that he is very much interested in new articles if the manufacturer could prove to him that these articles were of value to him. He has also shown that he is interested in improvements of old and time-worn articles—even that he is willing to throw away these old articles and replace them with the new ones if he could be convinced it was worth his while.

But there is one thing that the reader demands—and that he demands more and more every day. And this is it:

That the advertisement be just as clear as possible; that the way in which it is written be simple, brief and stick directly to the point. When he is reading an advertisement of valves, he does not care to be told a little incoherent anecdote concerning the Shah of Persia and his favorite Fatima.

In the early days of advertising the man who could talk in the floweriest language about the article he wished to sell, usually gathered enough shekels to plant several flower beds. But that was the period when the reader who answered an advertisement considered getting "stung" as part of the fun. That period of advertising, fortunately, did not last long.

Today, it's confined to the circus and an occasional patent medicine ad. The *influential* advertiser now is the one that sticks strictly to Facts and its twin sister, the Truth. And the reason is that the reader makes this form of advertising—and this form alone—pay the best.

* * *

The fellow who boasts that he never reads the advertising pages of his paper is like the fellow who boasts that he never takes a bath. Both require strenuous treatment, and both are looked upon askance by the rest of us normal beings.

* * *

Don't blame a concern because it cannot tell you *everything* in one advertisement. You can't crowd a week's supply of water into one boiler, all at once; you've got to feed it in instalments.

Follow this golden rule: "What you don't see, *ask for.*"

* * *

There's an awful lot to learn in the big business of coal mining and the advertisements in COAL AGE are doing their part to help you learn it.

Do you read them *always* and *thoroughly?*

COAL AGE

Vol. 1 NEW YORK, MARCH 2, 1912 No. 21

WHETHER or not there are periods of seismic unrest which are conducive to mine explosions, there is no doubt of there being at present a period of world-wide labor unrest which is likely to cause a destructive upheaval in the international coal situation.

Belgium is struggling in the throes of a serious, although local strike. British miners and operators have split principally because of the owners' refusal to concede a minimum wage contract, and unless the government can persuade the miners to return to work pending a further discussion of the questions at issue, the mines of Great Britain will be closed indefinitely. The momentary quietude in Germany is largely due to her desire to capture the British trade, which will be thrown open to her in case of a suspension at the English collieries.

When asked the cause for such disturbed conditions, most of us point to the average advance of 27 per cent. in ten years in the price of such necessities as bread, eggs, meat, milk, etc. We are told that wages must be raised correspondingly. But a look into the question shows that district engineers and mine foremen in the anthracite field a dozen years ago, received from \$80 to \$100 per month, which compares with \$110 to \$150 paid for the same work today. At that time firebosses received \$60 to \$75; at present, several large companies pay these men as high as \$90. The anthracite miners' wages have not been advanced materially since the award of the Strike Commission in 1902. But their annual earnings today are 25 per cent. greater than they were a decade ago. Bituminous miners have profited in a like degree. It is evident, therefore, that wages all along the line have recognized the general increase in prices of common articles.

Without belittling the importance of the actual higher cost of living, we suggest that at present, most of us specify as necessities many things formerly considered luxuries. Advances in all art or science, from better transportation to phonographs and moving pictures, are educative in character. We don't so much miss what we haven't had, but once we partake of better things, it's hard to plebeianize our tastes again. Too often we forget that a 40c. slice of roast beef will put more strength in our good right arm, than a half-dozen frogs' legs at \$2 a portion. It seems that only the rich man knows that happiness and health can't be purchased at so much per pound.

There are, however, other causes than the "cost of living" to account for the present labor situation in our coal industry. Things become rusty from disuse; an arm not exercised becomes paralyzed and degeneration sets in. A few weeks ago, German imperialistic newspapers declared that only a great war would unite the people of that country, make them loyal to the throne, and save the nation from Socialism. The assertion was based on the truth that "although a faction will fight within itself, you can generally count on a united front against an enemy from without"

Less than one-fourth the miners in this country are in good standing in the Union; the leaders figure that a strike might bring a majority into the fold. They have planned for several years to better their position at this time, and contracts in all fields were made to expire simultaneously. It was hoped that the country would be in a prosperous condition so that in case of a general strike, the men could find temporary employment in other industries and the public would contribute to maintain the strike as was the case in 1902.

However, fate has ordained otherwise, and conditions are not propitious for carrying on a successful contest. The people realize that coal owners have had hard sledding for years—only in exceptional cases have operators made fair interest on their investment. It is therefore common knowledge that any wage advance must be added to the price of coal. Labor is not scarce and the men could not secure work to tide them over a suspension. A simultaneous strike therefore in both the hard-coal and the soft-coal fields seems out of the question. Support must come from within the Union, so the men in one field will be compelled to support those who are idle in the other branch of the industry.

For several years, the bituminous states have received principal attention; during each suspension, the unorganized fields (chief enemies of the union) have secured new markets, and were benefited directly by the strike. Without attempting to prophesy, it is probable therefore, that trouble this spring will occur entirely in the anthracite field. The operators are better prepared than they were ten years ago, and with general business quiet as it is today, things don't look particularly encouraging for the miners' side of the controversy.

The Trinidad District in Colorado

By F. W. Whiteside*

The second and concluding article on the coal operations of southern Colorado. The mining and haulage systems are described, together with some notes on a new, convertible, steel, coal- and cattle-car which is being adopted by some of the Western roads.

*Chief engineer, Victor-American Fuel Co., Denver, Colo.

The different types of the crossover dumps are commonly used, among them the Phillips, the Wilson, and the Mitchell. The Hansen-Hayes tipple which is receiving such favorable consideration in the East, will undoubtedly come into use in this territory in the near future, although, so far as the writer knows, none have been installed in this district as yet.

Owing to the number of operators in the field and the consequent amount of competition, the preparation of coal for the market has become one of the fine arts.

Preparation of the Coal

The ordinary shaker, revolving and stationary screens are used. With the first named, from two to four sizes are made and loaded directly into railroad cars. Both the diamond-head bar and the perforated-plate are used, the latter having preference, as it produces a more uniformly sized coal with less dust and slack. There has been some diversity of opinion regarding the use of the square, oblong, circular or eliptical perforation for the screening plate. Each has had its adherents, but it now seems settled that the best preparation is obtained from the circular perforation and, almost without exception, all new screens are so equipped. The customary inclination given to screens of this type is 14 degrees.

The revolving type is ordinarily used to supplement the shaker or stationary screen in the preparation of slack and of the finer sizes for the washer or market. It will be found either under the tipple or up in the top of the washer. It would seem unfortunate that such conditions as heights and capacities make its use difficult on the tipple as a substitute for the present screening arrangement, as there is so little vibration connected with its operation and the resulting product is of such high quality. Both woven-wire and perforated-plate are also used, the former giving the best results. The screens in use in the district vary in size from 3 ft. 6 in. to 7 ft. in diameter and from 8 to 22 ft. long. The ordinary working pitch is about 5 degrees.

The stationary bar-screen is the natural pioneer and when properly constructed and operated, gives satisfactory results. The usual difficulty, in connection with the use of this screen is that its capacity is overcrowded. Usually an entire pit car of coal is dumped in a single mass which holds together as it slides down the bars. There is not enough obstruction in its path to turn over the lumps on the bottom, so the slack rides down on top and is delivered with the lump coal into the car. By the use of a suitable feeding device the coal is delivered upon the screen in small quantities and ample opportunity is given the finer sizes to pass through the bars. A feeding device is also of wonderful aid in prolonging the life of the box-car loader. Many of the larger mines load mine-run and engine-lump almost exclusively for railroad use. This is particularly hard upon the box-car loader unless the product is fed into it slowly.

The bar screens in this district measure from 4 ft. 6 in. to 7 ft. in width, from 16 to 24 ft. in length and operate on a pitch of 28 to 30 degrees.

Mine and Railroad Cars

In order to make a convertible car, the Western railroads are, many of them, building a steel frame drop-bottom cattle-car with side and roof doors. These cars are used for the transportation of stock, especially cattle, in the shipping seasons and for coal and coke the balance of the year. In the designing of a number of the newly constructed cars, the builders have lost sight of the need of a standard height for all car floors, side doors and roofs. As a consequence a box-car loader, set for a sandard height car floor is oftentimes too low to enter the side of the box- or cattle-car, on account of the excessive height of its floor. It is unsafe to raise the loader as the next car may have a low door which will not permit it to enter. It is true that there are certain makes of loaders which permit of vertical adjustment, but they are not always suitable for the loading conditions of a given mine. It seems unfortunate that a certain standard of height cannot be maintained for all coal-carrying cars.

Double-inlet Sirocco Fan Installation at the Hastings Mine

Pit cars of both wood and steel are used. The selection of the material being dependent upon the several governing conditions about the mine. Wood cars are used more numerously than steel, probably on account of their smaller first cost and the ease with which they are repaired. One of the largest operators in the field has recently taken a new stand in this matter and placed a large order for steel cars, believing that with a long haul there will be much less leakage of coal than with the wooden car.

There is considerable diversity as regards dimensions of the cars used in this district, due to the different heights of coal, pitches of the seams and capacities of the mines. The range is from 7 to 10 ft., end to end of bumpers and from 2 ft. 6 in. to 4 ft. in height above top of the rail. Both roller-bearing and plain wheels are used, besides at least a dozen different patent wheels. All tracks have a 3-ft. gage.

Railroad Yards and Scales

The 100-ton, 74-ft. standard track scale is most generally used for weighing empty and loaded railroad cars, while

they are standing under the tipple. The shorter and lighter scales are gradually passing out of use. The increased weight of railroad cars and their proportionately increased capacities have brought this about.

The railroads are now installing concrete and steel scales, the only wooden portions being the coping and deck. During the past year the Victor-American Fuel Co. installed four, 74-ft., 100-ton scales with concrete foundations and steel construction throughout, including the coping and deck. It is their practice to place all scale tracks on a 2 per cent. grade to enable the loaded cars to start readily in the most unfavorable weather. In order to attain this grade a tapering plate girder was fabricated which measured 36 in. at the high end and 18 in. at the low. Resting on the top of each girder, is a 2-in. oak plank, running the full length of the scale, to serve as a cushion; upon this is laid the steel deck, covering the scale and finally the track rails, which are securely bolted through deck and cushion into the girder. These scales have given satisfactory service.

Delagua Tipple, Equipped with Crossover Dumps and Three Car Feeders

A View at Primero, Showing Typical Miners' Dwellings

Power Plant, Tipple and Washery at Hastings, Colo.

The usual practice of landing the empty railroad cars at the upper end of the yard and then dropping them by gravity to the tipple and on to the loaded storage tracks is generally followed. There are usually from two to four loading tracks under the tipple and the gradient varies from 1 to 2 per cent. It is customary to provide a sufficient number of derailers to take care of runaway cars. The size of the yard is made as nearly proportional to the tonnage as possible: the usual allowance being a foot of track per ton of production for both the empties and loads.

System of Mining

Both the double- and triple-entry systems of mining are in use. In point of numbers there are probably more mines in the district employing the former. Ordinarily, entries are driven 12 ft. wide, although this standard may vary as much as two feet. Crosscuts are driven as often as necessary to keep good air up to the working faces, being generally placed at intervals of 60 to 100 feet.

The room-and-pillar method of mining with numerous modifications is used, there being no mine in the district employing the longwall method. The accompanying map of the Gray Creek mine of the Victor-American Fuel Co. may be taken as typical of mining practice in this district. Numerous geological disturbances will be noted among the more important of which is a broad and regular dike, crossing the Main South entry nearly at right angles between the 5 and 6 West Entries and a well defined and persistent fault with a throw of 14 ft. to the east and south of the shaft.

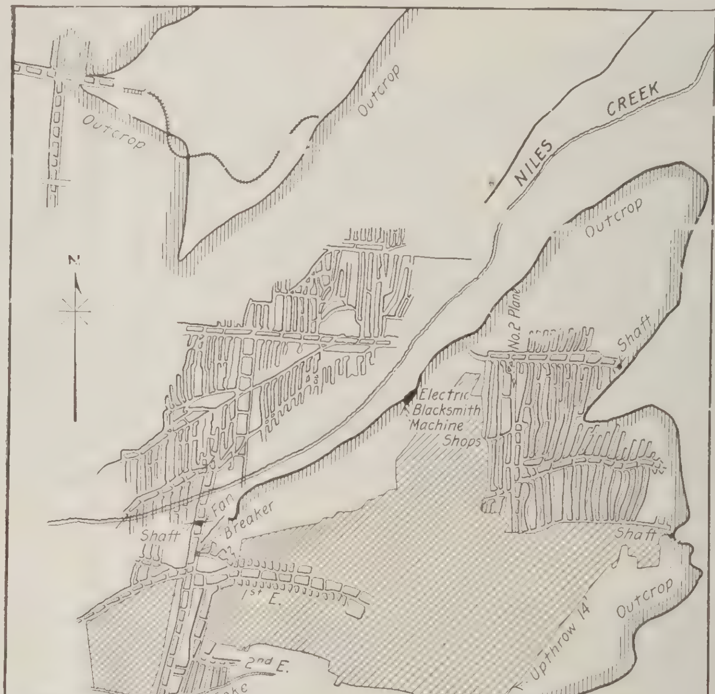
The original practice in the majority of mines in this district was not to pull pillars on the advance until the boundaries were reached in any particular section. When a mine was started on the retreat a great number of rooms and entries would be found so badly caved that enormous expense was incurred to put them in shape for the pulling of pillars and often large blocks of valuable coal were lost, as will be noted on the accompanying map. Added to these difficulties a serious squeeze often occurred.

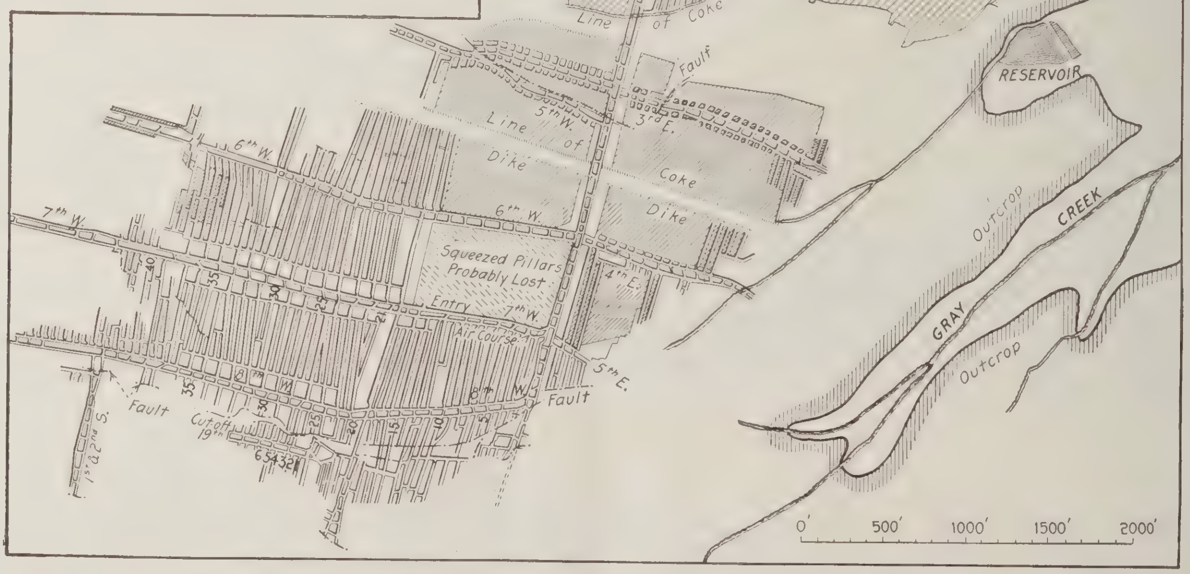
In later years the old practice has, to a large extent, been abandoned and a number of systems devised by which the pillars may be pulled as soon as possible after rooms are finished without doing injury to the permanent haulageways. This arrangement has the advantage of permitting the concentration of a large number of men in a small area, besides simplifying the ventilation and haulage. The panel system, with certain modifications has a number of followers, who claim excellent results from its use.

Rooms are, whenever possible, driven either on the strike or on some angle up the pitch. The usual width is from 22 to 25 ft., although some are driven as narrow as 18 ft. and others as wide as 30 ft. Unless the amount of cover is excessive the pillar is approximately the same width as the room. The practice of driving long rooms, 600 to 700 ft., has been generally discontinued and the average length of rooms is now from 300 to 400 feet.

Methods of Shooting

The coal is removed from the solid both with and without powder. Several operators have experienced considerable difficulty in preventing the use of dynamite which so badly shattered the coal that the percentage of slack ran high. This practice has been finally discontinued. Black and permissible powder are used exclusively except when in grading hard rock is encountered. Then dynamite is resorted to. The shots are fired by regular shotfirers employed for that purpose.





Map of the Victor-American Fuel Co.'s Gray Creek Mine Showing Typical Faults and Dikes

The number of mining machines in use in this district, at present, is not large, but steadily increasing, especially where mining is carried on in low coal.

The holes for shooting are bored by hand. Considerable experimental work has been done with the hydraulic cartridge. This device is a modified form of the hydraulic jack and could it be made to work successfully in all these coals, would be a great boon to miner and employer as well. It is a well-known fact that in certain coals, it has proved a decided success, but there seem to be others, in this field, which, on account of their elasticity and toughness, do not yield readily to the cartridge. It is probable that with a few simple modifications it can be made to do the work successfully in all coals.

Ventilation

In addition to its many other advantages the hydraulic cartridge will cut down the proportion of slack at least 25 per cent. As mined today the slack in ordinary mine-run varies from 35 to 60 per cent., the percentages lying mostly between 45 to 50.

The ventilation of the mines is handled in practically the same manner as in other coal mines the country over. The main haulageways usually carry the fresh air into the mine, while the back entries, or air courses, carry the return air. The air is split whenever a given area can be better served by so doing. Overcasts are used much more frequently than undercasts. They are ordinarily built of old rails, brick and cement, making them both cumbersome and expensive. Cylindrical pipes of extra-heavy galvanized-iron for this purpose would be light, comparatively cheap and much more easily han-

dled. Probably something along this line will eventually be adopted.

Brattices and doors are usually made of wood, but since the terrible fatalities of the past two years, in which so many lives were lost, the wooden door has been giving way to an interchangeable steel one and the old style brattice to one built of rock or brick laid up with cement mortar. So-called noncombustible brattice cloth is used, but, as this material looses its noncombustible property in time, great care must be exercised to protect it from fire.

Mine Lighting

In all mines where electric power is used, the main haulageways and partings are lighted with incandescent lamps. In nongaseous operations, the miners all use the lard-oil pit lamp.

Instruction and First-aid Car of the Victor-American Fuel Co.

The storage battery electric lamp would appear to be the future mine light. A local man, V. Patton, has perfected and patented a device, by which, in the event of the insulation wearing through or any other accident happening to the lamp whereby an arc would be made, the current is automatically cut off.

The operators have been experiencing great difficulty in teaching the ignorant miner the proper care and use of his safety lamp. It often happens that he becomes dissatisfied with the amount of light his lamp is furnishing and keeps turning up the wick until he has the gauze so badly smoked that the lamp is unable to burn. He then proceeds, if possible, to open the lamp. It has become necessary, in a number of cases, to subject the offender to fine or imprisonment in order to check the practice. The new lamps now purchased are magnet-locked, which will eventually obviate this trouble.

The Dust Problem

The Trinidad district is located in a rather dry, arid country. There is a small sub-surface water flow which is not, however, of such extent to make pumping a serious problem except in a few cases. In all mines in pitching seams considerable water finds its way to the lowest levels from which points it must be pumped to the surface. All other parts of the mines are dry and inclined to accumulate dust unless careful sprinkling is maintained. This is now being done in a systematic and thorough manner, the dust being washed from the timbers and sides of the passages and the floors thoroughly saturated at regular intervals. The operators now employ a large number of private inspectors, who give every detail, affecting the safety of the men underground, their most careful attention.

There are approximately 14,770 men employed in and about the coal mines of Colorado of which number, 5550 are working in the mines of the Trinidad district. The wages paid are good, when the class of labor obtainable is considered. A good miner earns as an average about $125 per month after powder, light, hospital and rent deductions are made; the more inexperienced will make from $70 to $90. The wages of drivers and other company men are in proportion.

Miscellaneous Details

As a usual thing the operator furnishes the miner's dwelling house, charging him a small rental. In some cases a small charge is also made for water, but usually it is furnished free with his house. His fuel and light are given him at cost plus from 10 to 20 per cent. He is provided with medical and hospital attendance by the payment of a small fee. The sanitation of his dwelling is regulated and inspected. His children are obliged to attend school until at least 14 years of age. This is the law and it requires the combined efforts of the officers and the operators to enforce it, as the miner would often take his boys underground as soon as they are strong enough to handle a shovel. Taken altogether the miner is happy, contented and prosperous and his condition is improving every year.

Great attention is being paid, by the larger operators especially, to first aid and rescue instruction. A proficient instructor is in charge who looks after all rescue and first aid apparatus and who gives instruction upon these subjects to regular classes composed of miners and company men generally.

Regular rescue crews are maintained which are held in readiness to go to the assistance of any mine in this or neighboring districts which may need them. A number of heroic men have thus given up their lives in the service of the unfortunates in other mines than their own. The U. S. Government car, in charge of Prof. Roberts, spends a great deal of time in the district and is doing most excellent work.

In 1910 the total coal production of the state of Colorado was 12,104,887 short tons of which amount, 5,595,664 tons were mined in the Trinidad district. There are 3164 beehive coke ovens in the state, although in the year 1910 some of them were not working. The Trinidad district has 2960 ovens of which number 2400 were burning during that year, in which time, the total coke production of the state was 1,190,901 tons and of the district 1,095,922 tons.

Matanuska Coal Field

The high-grade coals of the Matanuska Valley, Alaska, are the subject of a timely report just issued by the United States Geological Survey. The Matanuska coal field is the area to which Secretary Fisher recommended that a Government railway be built, and the Geological Survey report, with accompanying detailed maps, showing the areas underlain by coal strata, the most feasible routes for railway approach, and other specific and authoritative information, constitutes a valuable contribution to the present Alaska fuel problem.

The report is issued as Bulletin 500—"Geology and Coal Fields of the Lower Matanuska Valley, Alaska," by G. C. Martin and F. J. Katz. The accompanying maps show the geology, structure, and position of the coal beds and the report gives detailed measurements of the individual coal seams and analyses of the different grades of coal.

The maps, which are on the scale of a mile to the inch, will enable the constructing engineer to lay out the most feasible railroad route and will also provide the coal miner and operator with an adequate base for planning the work of prospecting the individual coal beds through drilling, shaft sinking, or tunnel driving.

Notes on Underground Fires

By James Ashworth *

Instances of fires caused by criminal negligence, carelessness and the disregard of rules and mine regulations. Lessons taught by mine disasters. Rescue apparatus. Spontaneous combustion in mines. Humidity. Microscopic examination of coal. Effect of mine temperature. Direction of air current. Iron pyrites in coal. Manner of handling mine fires.

*1109 Hornby St., Vancouver, British Columbia, Canada.

Mine fires naturally result from a large variety of causes. Many, and indeed the majority of mine fires, are the result of criminal negligence of the rules and regulations made to safeguard the lives of miners; many more arise from the gross carelessness of miners or the mine officials.

The worst case of criminal neglect of rules that ever came under my personal notice occurred in a mine in which safety lamps were used and no open lights permitted. On one of the main roads in this mine there was a blower of gas that had been in continuous active operation for a considerable time. It was the duty of one of the mine officials to inspect this blower, after the miners had left the mine, each day. On making his round of inspection one afternoon he was startled to find the blower of gas had been ignited and was burning fiercely. Fortunately he was able to extinguish the flame before any serious damage had resulted. It was never discovered who was responsible for the ignition of the blower, as a subsequent investigation and search of the miners did not reveal any matches or lamp keys in their possession. Evidently someone had disobeyed the regulations of the mine, either by carrying matches or by tampering with the safety lamp.

A notable instance of gross carelessness on the part of the miner is found in the disastrous and fatal fire that occurred at the Hamstead colliery, in England, sometime since. In this colliery the miners used common tallow candles, which were stored at the bottom of the downcast shaft, in a large box. It was the custom for each miner to cut off his daily supply of candles from the bunch that was kept in this box. In the present case a miner, instead of cutting his supply of candles from the bunch, burned the wick or cord holding the candles and dropped the bunch back in the box and closed the lid. When the fire was discovered later it was burning fiercely, having ignited the woodwork about the pit bottom. As a result of this fire a large number of lives were sacrificed.

The fan at this colliery was not reversible, and the accident aroused great interest in the question of whether the ventilating fan at a colliery should not always be so constructed that the air current in the mine could be reversed on short notice. The question of reversing the air current in a mine, while the men are at work, has never been seriously debated and is still unsettled. Many claim that the cure would be more dangerous than the disease, because the men remaining in the mine and ignorant of the changed circulation would be trapped and suffocated.

The terrible disaster at the Cherry mine in Illinois in November 1909, by which 259 lives were sacrificed, was the result of combined carelessness and negligence. The fire was started by a car of baled hay that was pushed too close to a burning torch at the side of a track. It was bravely fought for some time by the men at the bottom of the shaft; but these men failed to send word in to the workers in the mine, in time for them to make good their escape. Many of these men were trapped, their escape being cut off by the smoke and gases of the fire. The ventilating fan at the Cherry mine was reversible, but the reversing of the air current, which was done later, cost the lives of some of the rescuers.

The Cherry disaster taught many useful lessons, among these may be mentioned the danger of an unprotected light on the shaft bottom; the need of greater caution in the handling of combustible material being taken into the mine; the danger of reversing the air current; the need of greater fire protection at the shaft bottom; and the need of fire drills. The rescue of twenty-one men from this mine, after a period of eight days, teaches that it is unwise to assume in any case that all of the miners in the mine are dead or beyond rescue. There should always be hope till the absolute truth is known.

I will mention but one other instance, which occurred recently in the old Hednesford colliery, England, and which shows the criminal neglect on the part of the mine management to establish a proper system and supervision of the underground workings. At this colliery five men lost their lives by suffocation caused by the smoke of a fire that started in a cabin on the intake road. It is supposed that a boy when trimming his lamp in the "shukey" (underground cabin) set apart for that purpose, threw a burning wick on the floor and did not take the trouble to extinguish it. The cabin was located about thirty yards from the bottom of the downcast shaft. When the fire was discovered the flames had traveled along the oil-saturated floor and ignited some cars loaded with coal that were standing ready to be hoisted up the shaft. A workman nearby seeing the flames made an attempt to extinguish them, but failed to do so and went for assistance. The overman who first arrived ordered the opening of the separation doors leading to the upcast shaft. This short-circuited the smoke and gases of the five and kept the most of it from entering the mine, where about one hundred men were at work. A little later the under-manager arrived and ordered the doors to be closed again. Most of the men working inside had escaped, but five men, including one brave fellow, Thomas Stokes, who volunteered to rush through the smoke to warn the inside men lost their lives. When the flames were finally extinguished but one pony out of twenty in the mine was found alive.

This last instance points several lessons. An astonishing feature is the fact that during the excitement no one thought of stopping the fan. Among the lessons to be learned are the need of more thorough supervision underground; the need of better fire protection and fire fighting apparatus underground; and the building of all shanties and underground enginerooms and pumprooms of incombustible material, as far as practicable.

Use Of Rescue Apparatus

In England, it appears to be customary for a certain group of collieries to combine together and maintain a central rescue station and brigade. In the instance just mentioned an early call was made on the station for help. At the time the call was made the principal part of the available force of the station was away, having been called to assist in extinguishing a fire at the Jammage colliery. In response to the second call, however, a few men were sent with rescue apparatus. At the inquest, referring to the use of rescue apparatus it was pointed out that even if the apparatus had been on the ground it would have been of little use because there was no means of bringing the men through the smoke.

Here is an object lesson revealing the fact that, in all cases, the rescuers should each carry a second apparatus in addition to the one worn, to enable them

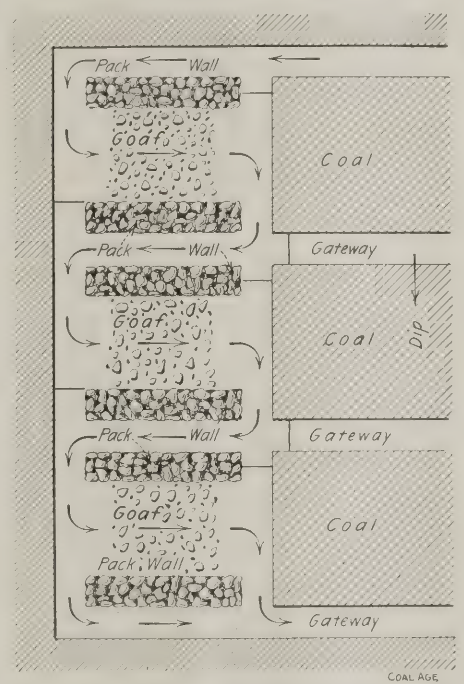
to bring out men that may be found alive. The importance of this was demonstrated at the Bellevue disaster in Alberta, Canada, December 7, 1910, when two men, although they had never worn a Draeger apparatus before, were safely brought through a considerable length of airways filled with smoke and gases. For this purpose it is evident that the apparatus should not be heavy or cumbersome. Many of the forms of apparatus in common use are poorly adapted for mine work, on this account. Mine-rescue apparatus should be so simple that a novice, who has never worn the apparatus before, can put it on and use it successfully. An important point in rescue apparatus is that it shall not have any small apertures that can become suddenly clogged. This has in some instances caused the failure of the apparatus with fatal results.

Spontaneous Combustion

A large majority of underground fires are undoubtedly due to spontaneous combustion, resulting in what are generally known as "gob fires." These form a very important class of mine fires. Such fires have always been a great source of trouble in mining and their origin is still a matter of speculation with a large number of mining men, whose opinions differ widely as to the exact cause and the best remedy to be applied. The truth of this statement is evident from the numerous references to the subject in papers contributed, from time to time, to scientific journals and institutes. Quite recently, at an inquiry in regard to the cause of an explosion, a mine inspector suggested the following points might well be investigated; namely, (1) the affinity of oxygen for the various coals, shales and rocks; (2) the heat conductivity of such coals, shales and rocks; (3) the relative inflammability of such coals and shales; (4) that analyses of the various coals and shales be made, and the gases contained in them ascertained; (5) the structure of various coals as shown by the microscope; (6) the hydroscopic moisture content of various coals; (7) the fineness of the particles of crushed coals; (8) the shape of such particles; (9) the temperature at which oxidation becomes destructive; (10) temperature and humidity of the air in various parts of mines taken every four hours of the day. This classification suggests, at least, how much there is yet that may be learned in regard to the spontaneous ignition of coal.

Humidity In Mines

The writer firmly believes, as the result of his own experience of many years in mines where gob fires were a perpetual trouble and danger, that the humidity of the mine and the mine atmosphere represents the chief factor of safety. It may be generally stated as a fact that will be accepted by all, that if it were possible to make the air in mines practically dry there would be no gob fires. This, however, is a practical impossibility, in mining. But, owing to the increase of the heat and the temperature in deep mining, and the difficulty the miners experience in working in a moist, warm atmosphere, it is necessary in deep mines to maintain, as far as possible, a drier condition of the air current. In other words, it is important to avoid humidifying the mine air as much as possible. This has led some to think that a seam of coal that is subject to spontaneous combustion at a moderate depth, might be less susceptible at a greater depth. This, however, is not the case, since there is always sufficient moisture in the air of mines to make combustion possible, and the increased heat favors combustion.



Showing Proposed Direction of Air Current to Prevent "Sweating" in Mining on Deep Pitches

I would suggest that the daily and systematic use of the hygrometer throughout a mine subject to spontaneous combustion is of the greatest practical value as a means of indicating, (1) any increase or decrease in the heat of the air currents; (2) and most important, any abnormal rise in the water-vapor content. The latter observation gives the earliest indication of any tendency to spontaneous combustion and the development of gob fires, in mine workings.

No experiments have been made, as far as my knowledge goes, to discover what effect hygroscopic water has on the liability of coals to take fire spontaneously. We are aware, however, that the higher the percentage of hygroscopic water in coal the more easily the coal disintegrates; and this would naturally increase the rate of oxidation rapidly.

As an illustration of the influence of moisture to produce spontaneous combustion, I recall an instance narrated by an engineer, then president of a society of mining engineers but now deceased. He was explaining why he substituted fan ventilation for furnace ventilation, in a mine. He stated that the mine was very subject to spontaneous combustion. At week ends and holidays it was customary to slow down the furnace, with the result that moisture condensed on the refuse thrown back in the gob. He observed that this moisture still remained when mining was again resumed, and before it dried up it was covered by fresh refuse. He stated, in conclusion, that he considered this moisture was the primary cause of the spontaneous combustion and frequent occurrence of gob fires in his mines. As a test, a fan was installed and kept running at a regular speed throughout "play days," with the result that the moisture was reduced and there were fewer cases of spontaneous combustion in the mine.

Microscopic Examination Of Coal

In passing, I desire to refer to a suggestion from a scientist, a Mr. Lomax, who has recently made a close microscopic examination of different coals. Mr. Lomax has produced some marvelously fine slices of coal for examination and for lantern purposes. These slices show that coal is not all black, and the resinous parts are easily distinguishable. He suggests that a further examination may prove of great value to mining by showing why one coal dust is more explosive than another, and also why one coal is more susceptible to spontaneous combustion than another. It has long been held by authorities that the fineness and the shape of the particles of crushed coal resulting from the natural pressure and movement of the strata, influence the tendency of the coal to spontaneous combustion, the reason being based on the ground that the finer the coal is crushed the greater the extent of surface exposed to oxidation, and the more rapid the oxidation the greater the heat developed.

In some deep coal mines the natural heat of the strata often ranges from 90° F. to over 100° F. While no actual data has been thus far produced to show that such increase of the mine temperature assists to any great extent the spontaneous combustion of the coal, yet there is a growing suspicion that it does exercise an undesirable influence in this regard, especially where the enfolding

strata are highly bituminous. Recent experiments have shown that tar is distilled from coal at a low temperature, and this fact may materially increase the liability to spontaneous ignition of the coal. It is reasonable to suppose that the high temperature and moist atmosphere, in many deep mines, greatly increase the risk from spontaneous combustion.

In the mining of an inclined seam of coal subject to spontaneous combustion the direction of the ventilating air current is important. See Fig. 1. Instead of the usual ascensional system of ventilation I would suggest that in this case the air current should be entered at the highest point in the mine and from thence conducted downward, especially if the mine is being worked on the longwall system. In making this suggestion I have in mind the effect of the deposition of moisture on the waste stored in the gob, to which I have previously referred, as assisting the disintegration of the fine coal and increasing the tendency to spontaneous ignition of the coal. It will be remembered that the capacity for carrying moisture in the air current increases with the temperature. If the cool intake air enters at the highest point of the workings its temperature gradually increases as it is conducted to the lower workings. Its vapor-carrying capacity is therefore increased regularly, and no moisture will be deposited in the face of any of the working places. On the other hand, if the cool intake air enters at the lowest point of the workings, this being the hotter portion of the mine, its temperature is raised and, as the air proceeds upward, it is cooled and deposits its moisture, from time to time, at the face of each working place. It is this deposition of moisture on the refuse or waste that greatly facilitates spontaneous combustion.

Effect Of Iron Pyrites In Coal

In cases where iron pyrites is found in the coal the dampness deposited from the air current undoubtedly assists in the disintegration of the coal and encourages spontaneous combustion. In all the mines in which the writer has had serious difficulties with gob fires, iron pyrites has been present as a factor, and the point I would like to urge is that the greatest immunity from this serious danger is to be found in maintaining a dry (unsaturated) condition of the air current. An unsaturated air current will thus continue to absorb or take up moisture. There may, of course, be serious objections to this in the working of a mine generating explosive gas, especially where the mine has a tendency to become dry and dusty. The successful mine manager will have all of these conditions in mind and consider the influence of each.

Handling Mine Fires

The safest and most effectual, and in the long run the least costly way of dealing with a gob fire is to dig it out, whenever this is practicable. With present-day appliances this is not as dangerous work as it would have been years ago, when no oxygen apparatus was in use except the simple apparatus of Denayrouse, which consisted principally of an air-pump, but was often of great value. In many mines it is the custom to build clay walls or banks of sand and flue dust, so as to keep out the air and isolate the fire. In other cases, masonry walls or stoppings are built in the airways, as near as possible to the seat of the fire. In mines generating firedamp the work of isolating a mine fire by building stoppings is always attended with more or less danger. It is important that the work be done promptly.

The most recent disaster caused by the sealing off of a fire occurred in the mining of a coal field of deep inclination. A fire had started in the gob, but was not considered to be in a dangerous condition, and the management decided to first place dirt packs in the roadways and later to build masonry walls or stoppings. The places selected for the stoppings were at some distance from the seat of the fire. When the dirt packs were partly completed there occurred what is described as an "explosion," though no one appeared to have been burned; however, six men were asphyxiated. Unfortunately, at the present writing, there is no information available as to whether the so-called explosion was caused by the gases from the fire or by the firedamp generated in the inclosed space, or both combined; or whether the effect was simply a heavy fall of roof that drove the smoke and gases out onto the men and asphyxiated them. Only one man out of the six escaped alive. The account does not state in what stage of construction the stoppings were at the time of the disaster, nor to what extent the circulation of air had been stopped, and therefore no inferences can be drawn.

In the general discussion of underground fires, however, and without reference to their inception or surroundings, the question is open to argument as to which road should be closed first, the intake or the return airway. Speaking from personal experience, and that a most dangerous experience in this class of work, when seconds of time were important, the return-air road was plugged first, though the intake was not long behind. As a general rule, this course should be adopted, because as soon as the return airway is plugged the smoke is driven back onto the fire and thus forms on the return side—the most dangerous side of the fire—a barrier of gases containing too little air and too much carbon dioxide to be explosive. Besides all this, the intake air is forced backward by the products of the combustion, and the building of the intake stopping is then accomplished in safety.

The use of water to extinguish a gob fire will later do more harm than good, unless it can be applied in sufficient quantity to completely drown the fire. The better plan is to use water, if at all, in sufficient quantity only, to cool the heated matter as it is being dug out.

Underground fires wherever they occur, and from whatever cause they arise, are always dangerous and require the most prompt decision and determination in their treatment. For this reason the mine that is equipped with adequate apparatus for fighting such fires will be most assured of success. No set of rules could be drawn that would fit all conditions, and therefore the best remedy in the extinguishing of an underground fire is a cool head to direct the operation.

The Big Stick for the Operator

A correspondent in the *New York Times* under the euphonic *nom de plume* of "Gentleman Janitor" writes as follows:

I will begin by saying that my subject is coal, furnace coal for the hot-air furnace. I am one of three house owners who compose an organization known in our Brooklyn neighborhood as gentlemen janitors. Why? Because we look after our furnace requirements mornings and at bedtime. Each has "a man" who fills in between times and puts out ashes.

We three know just what sort of coal we pay for at the rate of $6.75 a ton just now, though every April it is Brooklyn's custom to lay in a winter supply at the short price of $6 a ton. All householders who employ "a man" for the entire care of a furnace know not what they pay their money for. But we gentlemen janitors do, and we know that fully an eighth of every ton of furnace coal (egg size) is made up of offscourings from the coal regions of Pennsylvania—slate, a few real stones, slag, and iron ore. The grate of my furnace I have to rake out below fully three times a week, and sometimes the slag has to be dug away, in the form of a mat that forms over the grate. What remedy have we? A Congressional investigation? My complaint applies to all the dealers, or to four, anyhow.

GENTLEMAN JANITOR.

Brooklyn, N. Y., Feb. 19, 1912.

[Why go to Pennsylvania for coal experts when we live so near Brooklyn?]

Coal Mine Ventilating Equipment

By W. M. Weigel*

The relative advantages of pressure and exhaust fans under certain conditions of mining are here indicated and a discussion of reversible fans serves to point out the dangers as well as the benefits that may attend their use. Fan drives are considered and also the details of building construction. The sixth of a series of articles on mechanical ventilators.

*Associate professor of mining, Pennsylvania State College, State College, Penn.

The Sullivan fan like the two makes of high-speed fans mentioned in a previous article, has a large inlet as compared with the diameter of the wheel and has short blades, usually 42 in number, curved forward in the direction of rotation. Every third blade is larger at the center or back of the fan wheel and projects into the inlet space, as is indicated in Fig. 2. The distinguishing feature of this type of fan is the arrangement for changing the fan from an exhauster to a blower or vice versa. Instead of using doors or dampers for this purpose the whole hood or casing is revolved about the fan shaft as a center.

This hood is shown in Fig. 1 in the position required for blowing and in Fig. 3, it is shown adjusted for running the fan as an exhauster. It is turned by means of a hand wheel and a pinion that engages a gear segment on the hood.

Fig. 1. Ten-foot Sullivan Fan, Blowing Position

When blowing, the air passages on either side of the fan are open to the atmosphere on top and the wings on each side of the discharge chimney serve to close the openings between the fan drift and these passages. When exhausting, the wings then close the openings at the top of the side chambers and at the same time allow a free passage from the drift to the fan inlets. The air current may easily be reversed without stopping the fan. This type of fan is made in sizes from 6 to 20 ft. in diameter and is always built with a double inlet.

Pressure vs. Exhaust Fans

Ordinarily, a fan may, with equal facility, operate either by blowing air into the mine or exhausting it from the mine. The construction of the fan wheel is practically the same in either case, the only difference being in the arrangement of the casing with regard to the discharge and inlet openings. The discharge of the exhaust fan is usually directed upward and the chimney or stack enlarges towards its outlet to the atmosphere. The discharge of a blowing fan is usually taken off in a horizontal or slightly downward direction, and is only enlarged enough to make it equal in size to the connection with the mine opening. The power required to force an equal amount of air through the mine is the same with both systems.

Whether the exhaust or the blowing system should be employed will depend to a great extent upon the conditions of the mine and the methods of working. In American practice, the working entrance, whether shaft or drift, is kept unrestricted, or, in other words, it is made the downcast or intake when an exhaust fan is used and is made the upcast or outlet in case a blowing fan is employed. The reversal of this practice requires doors or air locks in the main operating openings, and these devices are a source of delay and annoyance. When the working shaft is the downcast, accumulations of ice, if the shaft is at all wet, are liable to cause trouble during cold weather. On the other hand, if the blowing system is employed and the intake is wet, trouble quite as serious may arise from the choking of the air shaft.

With the exhaust system, the atmospheric pressure in the mine is a little less than that outside. In case the fan stops the pressure in the mine will rise, tending to hold back the gases discharged from the coal and waste places. With the blowing system, if the fan stops, the air pressure will fall slightly, having the effect of a fall in the barometer, and allowing greater quantities of gas to flow into the working portions of the mine and haulage ways.

Where the blowing system is employed, the return airway is used for haulage and if the mine is gaseous this arrangement may not be advisable on account of the danger from drivers' lamps, or sparks from the trolleys of electric locomotives. On the other hand, hauling on the intake, which is customary with the exhaust system, befouls the air before it reaches the miners, and allows the dust from the haulage ways to settle where it is most dangerous. When hauling on the return, the dust and foul air are immediately removed from the mine without reaching the working face. In general then, where the mine gives off gas in any amount and is not dusty, an exhaust fan should be employed. If the mine is dusty and not gaseous a blower is to be preferred. If both dusty and gaseous, the case will usually have to be decided by determining which of the two conditions is the more dangerous, keeping in mind also the system of haulage that is to be employed.

Reversible Fans

With a suitable arrangement of doors or dampers and connections with the mine, any fan may be operated either as a blower or as an exhauster. The Sullivan fan is reversed by rotating the housing as previously explained. In general, making a fan reversible requires that the inlets and discharge be connected with both the mine opening and the atmosphere, the course of the air being determined by the position of the doors or dampers in the several passages.

In Fig. 4 is shown an arrangement of doors and stack damper that permits reversing a fan, primarily designed for use as an exhauster. In this arrangement the doors and dampers are connected by reach rods and toggles so that

the positions of all are changed at the same time and by one operation.

A reversible blowing fan for a slope mine is shown in Fig. 5, and the method of converting it into an exhauster is clearly indicated. When blowing, the side doors of the airway are in the dotted position, and the end of the spiral casing is in the position shown by the solid lines. When exhausting, the side doors are in the position of the solid lines and the movable part of the spiral casing is dropped down as shown by the dotted lines.

Many mines are now equipped with reversible fans, and such an installation has several important advantages. However, reversal of the air current, unless of such frequent occurrence as to render its operation entirely familiar, should be permitted only on the order of some competent person in authority. Otherwise the consequences may be disastrous. Just what effect a reversal of the air is going to have in a particular mine should be carefully studied out, so that in case of emergency (and reversible fans are usually employed for such cases) the right thing may be done.

In the event of a mine fire or explosion, the reversal of the current may serve to draw the smoke and gases away from the outlet best calculated to facilitate the escape of the men underground and thus be the means of saving life. On the other hand, when the location or extent of an accident is unknown, or the effect of reversing the air not previously determined, such a procedure may operate to cut off the means of escape, and add to the catastrophe.

Reversible fans may be employed for other than emergency purposes. If a mine has considerable natural ventilation the direction of which is opposite in summer and winter, the fan can be made at all times to operate with the natural currents and this is always a desirable feature, other things being equal. If a mine makes a large quantity of gas and there are considerable areas of gob or worked out portions for its accumulation, the fan, running as a blower during the day or working shift, will tend to hold back the gases in these places and prevent their overflow into the workings; then at night when the men are out, by running the fan as an exhauster the pressure may be decreased and the accumulation of gases drawn off and carried out of the mine by the air current, at a time when their presence in the main airways offers the least danger.

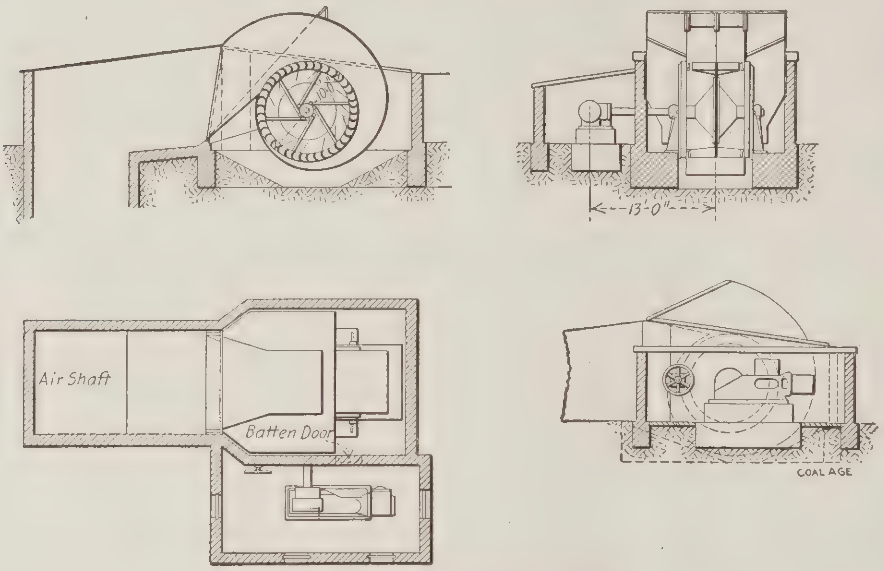


Fig. 2. Sullivan Fan and Fan House

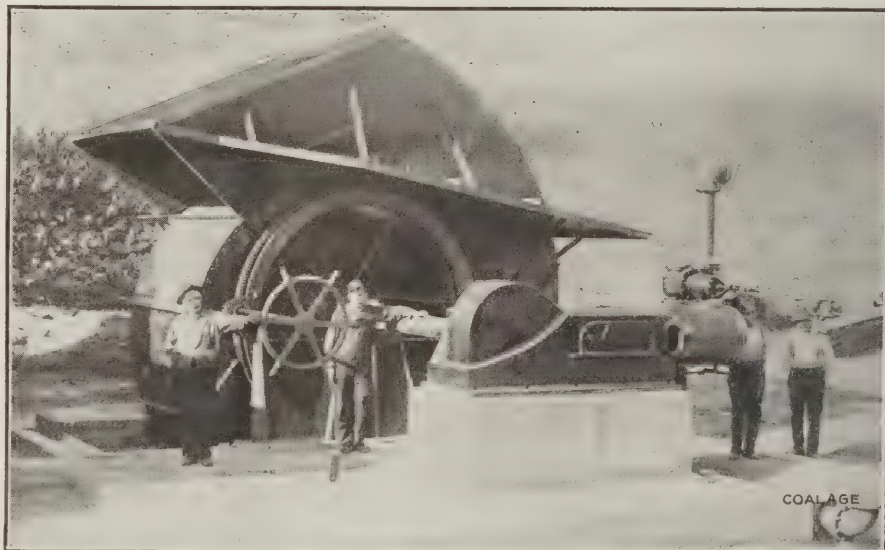

Fig. 3. Sullivan Mine Fan, Position for Exhausting

Location of Fans

The ventilating fan is found in many instances to be placed close to the inlet of the mine and sometimes directly in front of or over it. This arrangement should be avoided where there is any liability of an explosion, for in such an event the fan is almost sure to be wrecked. However, where there is no possibility of danger from this source, that is, where the mine is wet, and there is absolutely no gas, the fan at a drift mine is most conveniently placed directly in front of the airway. When the airway is a shaft, the fan should be kept at some distance from the opening if there is any chance of subsidence or caving.

By placing the fan to one side of the inlet and connecting it to the mine opening with a passage having a right angled turn, it is rendered reasonably safe from destruction, and may be further safeguarded by placing large explosion doors where the fan drift turns off from the entrance to the mine. For a shaft mine, the doors should be directly over the shaft and in the case of a drift or slope they should be set squarely in front of the entrance.

These explosion doors are preferably made double and as light as possible, using thin steel plate or lumber. With a blowing system, they should be weighted just sufficiently to overcome the maximum ventilating pressure required. With an exhaust fan the air pressure is sufficient to hold them closed. The doors should be made as nearly air tight as can be without causing them to stick in the frame.

Frequently these doors are not large enough to be of value in case of emergency. Their area should be at least equal to that of the shaft or entry, and greater if possible. The force of an explosion will tend to blow open the doors and save the fan, as the main explosive effect will travel in a straight line if given a chance, or until some powerful obstacle intervenes. To insure safety the length of the fan drift between the

turn at the explosion doors and the fan should be at least 4 to 6 times the width of the mine entrance. That is to say, if the airway is 10 ft. wide, then the fan should be placed not less than 40 ft. to one side.

Fan Drift Construction

Formerly fan drifts were, as a rule, light constructions of wood, the idea being that the force of the explosion would blow them down and protect the fan, but the danger from fire was a constant menace and it was difficult to keep them air tight, so present practice tends toward the use of steel plate, or masonry of brick or concrete. Steel construction for this purpose consists usually of plates 1/8 in. to 3/16 in. thick, well riveted at the seams and held in place by angles or tee bars bolted to the foundation. All should be kept well painted inside and out.

The floor of the drift may be of concrete and foundations along the sides should be carried well below the frost line. The floor should slope to a drain pipe connected with the outside, as the precipitation of moisture is often quite heavy in the drifts of exhaust fans. If the fan drift is of brick, the walls should be not less than 9 in. thick, preferably 13 in., and for high walls 18 in. The roof may be a brick arch but this construction is expensive and steel plates anchored to the brick walls or reinforced concrete is usually employed.

Concrete makes an ideal construction. It is as cheap or cheaper than brick, is more durable and requires less attention than sheet steel. The walls may be made thick and without reinforcing steel but perhaps a better and cheaper method is to use some one of the various systems of reinforcment adapted to walls, as danger of cracking is thus avoided. The roof may be made of the same material. Entrance to the fan drift should be arranged for near the fan by means of a double door or air lock. Fan-shaft journals, inside the drift, should be provided with a pipe for oiling from the outside.

The fan foundation should be substantial and carried to a sufficient depth, as the operation of a large fan is attended with considerable vibration. Brick or cut stone may be employed in its construction but concrete is usually better as well as cheaper, and is easily molded to form the lower part of the casing. In placing the anchor bolts, enough space should be left around them to allow for slight discrepancies between measurements made on the ground and the material furnished by the manufacturer.

The fan and casing are generally left uncovered, but a house must be built over the engine or motor and preferably this should be of brick, concrete, or other fireproof construction.

Every precaution should be taken to insure the safety and reliability of the surface ventilating equipment, as upon it depend largely, not only the continuous operation of the mine but the lives of the men underground.

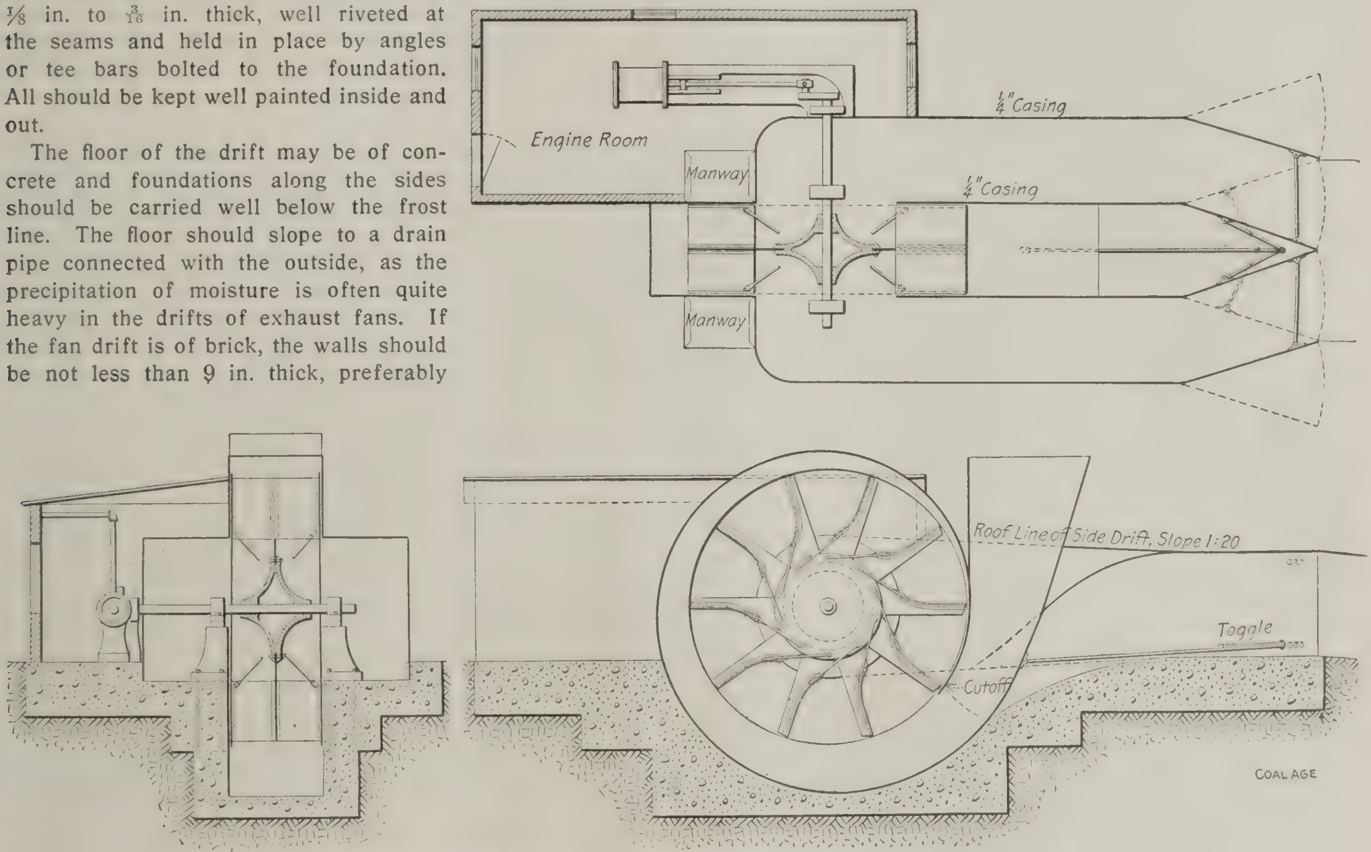

Fig. 4. Double-inlet Reversible Beard-Stine Fan and Fan House

Motive Power

Almost any available motive power may be employed for driving fans. Steam engines or electric motors, however, are the almost universally adopted means as gasoline or gas engines are as yet somewhat unreliable for the isolated localities in which fans are often placed, and water power is rarely found at hand.

Fans of large diameter and slow rotative speeds are best driven by direct connection to steam engines. As a large fan runs at practically constant speed and load, the most favorable conditions are presented for the economical operation of its engine. Direct connected corliss engines are used for many large fans where the speeds do not exceed 100 r.p.m. If higher speeds are required, then the fan may be belted to the engine or a high-speed engine employed.

Rope drives instead of belting are sometimes made use of in England and Europe, but not in the United States. As the fan and engine are usually located at some distance from the main power plant the engines are rarely run condensing. Moreover, water for condensing purposes may not be available at less cost than the saving made by using a condenser. The disadvantages of a belt drive are loss of power in transmission and the requirement of greater space, necessitating a larger building. There is also an increased chance of stoppage due to failure of the belt.

Often two engines are installed, one on each side of the fan. One engine operates the fan while the other is disconnected. Then, if the first should break down, the second can be connected in a few minutes and no serious delay oc-

curs. Such an installation, however, increases the first cost of the plant.

Electric motors are either direct connected, belted or geared to the fan shaft. Direct connection is to be preferred, but such an arrangement is as a rule, only possible with fans of high rotative speeds, such as the multivane and disk types. Slow speed motors can be built for the larger fans but their increased cost usually outweighs the benefits derived. Because of the small amount of attention they require, polyphase induction motors are admirably suited for driving fans.

Speed regulation may be obtained with a steam engine simply by throttling or by adjusting the governor. With an electric motor the speed may be varied by any of the means generally employed for this purpose, but operating at speeds less than normal is usually attended with loss of power in the controlling resistances.

A Difficult Piece of Shaft Sinking

Special Correspondence

As supplementary to the article, "Use of Grout in Shaft Sinking," in Coal Age of Feb. 24, an account is here presented of a shaft-sinking operation in which cement grout was successfully used to combat an immense inflow of water. A large emergency pumping plant is also described in this connection.

The construction of the Catskill Aqueduct is deservedly attracting widespread attention. It is easily understood that many important problems necessarily have to be solved when it is proposed to carry an enormous supply of water from a mountain district to a point 100 miles distant, conducting it across a score of valleys, some of them several miles in width, as well as across so deep and broad a river as the Hudson. The part of this work that is of greatest interest to the mining profession is the shaft and tunnel construction.

The aqueduct may be said, if one speaks broadly, to parallel the Hudson River. Consequently, the route cuts across the tributary streams. These are creeks or brooks of no especial importance, so far as size goes. However, they mark the position of valleys, some of which are a number of miles in width. One of the largest is the valley of Rondout Creek. In crossing at this point, the aqueduct drops far below the surface of the ground and the bottom of the creek, and thus makes the 4½-mile passage from one side to the other.

A Deep Shaft through Water-bearing Strata

A vertical shaft at each end, and a third, located at an intermediate point, will remain as permanent features of this work. In addition, five other shafts were sunk to the tunnel grade in order to facilitate construction. One of these, No. 4, is 500 ft. deep and 10x22 ft. in horizontal section. Eighteen months were required to put down this shaft, and it was flooded six times. The strata passed through were as follows:

Glacial drift	6 ft.
Helderberg limestone	226 "
Binnewater sandstone	39 "
High Falls shale	92 "
Shawangunk grit	134 "
Total	497 ft.

The trouble with water came, no doubt, almost altogether from the sandstone and the shale. But the water made its presence felt long before these strata were reached. A 4-in. test hole had been put down on the site of the shaft, and when, in sinking, a depth of about 80 ft. had been reached, a sudden inrush of water came through this hole, half filling the excavation. The emergency pumping plant had not yet been delivered; so the contractors were caught unprepared. However, by the use of an air lift and a couple of sinking pumps, the water level was lowered to a point near the bottom. A nipple was then driven into the hole and casing attached. The purpose was to fill the hole with cement grout. In order to carry out this plan, a

Looking Down into Construction Shaft No. 4

1-in. pipe was put down to the Shawangunk grit; that is, to the 363-ft. level. The water was now permitted to return. Pressures were thus equalized and currents prevented. The grout was made in the proportion of one part cement to one part sand and poured down the 1-in. pipe, this latter being withdrawn as the grout filled the hole.

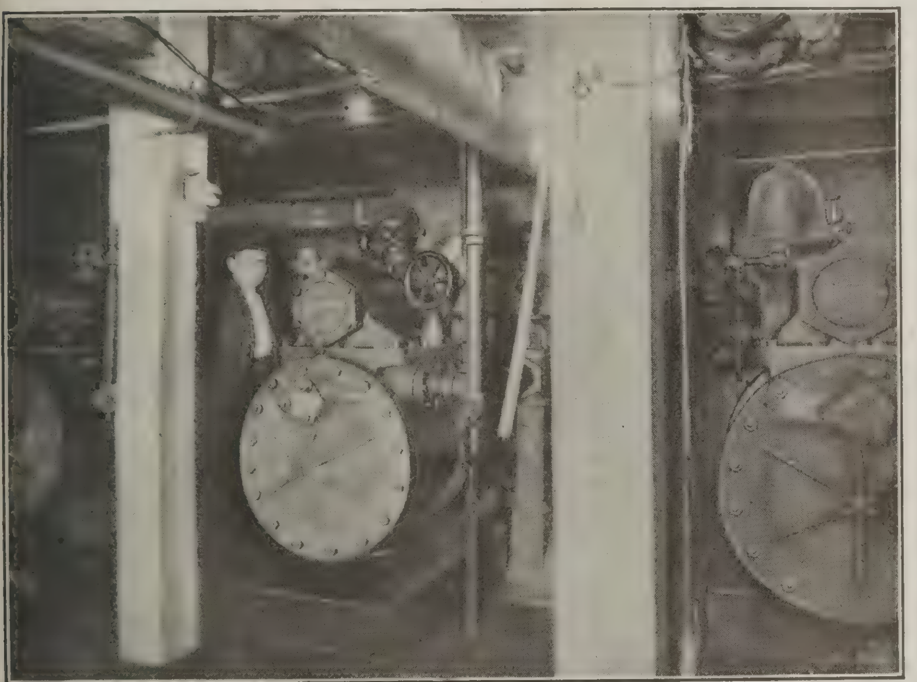
The problem of this one hole was solved as indicated, but the T. A. Gillespie Co. who were doing this work began to entertain fears as to whether the ordinary methods of shaft sinking would prove successful. It was understood that there was in the strata below, a great deal of water under considerable pressure. With subsequent events in mind, it is not difficult to see that a special pumping chamber in the side of the shaft should have been provided before permitting the excavation to pass out of the limestone. This arrangement was made later, but the delay was the source of much trouble. Excavation went on, and the sandstone was penetrated. At the 200-ft. level, the amount of incoming water was only about 225 gal. per min. However, during the drilling of the sump, an additional 600 gal. per min. came in suddenly through one of the drill holes, with the result that the shaft was flooded again.

After some trouble, the shaft was unwatered, only to be flooded three times more in as many weeks. Nearly all this water came in through bore holes that were probably in no case over two inches in diameter. When the fifth unwatering had been completed, the conditions below were known to forbid further progress without taking special precautions. In fact, it had been ascertained that there were large crevices a short distance beneath the bottom of the excavation running up to 8 in. in size. One of the largest of these crevices was distant only a foot and a half. As compared with the 2-in. bore holes, they promised plenty of trouble.

Grouting Up the Crevices

It was now proposed to deal with the water question by means of grout. Four special machines were set up at the mouth of the shaft. A 2½-in. pipe was led down the shaft to the bottom, where a 2-in. hose carried the grout to the point of use. At the beginning of operations, the grout gave some trouble by leaking back. It would come in through the spaces around the pipes and through cracks in the bottom. This difficulty was successfully met by mixing finely ground horse manure with the grout. The manure produced a clogging effect. Some grout was wasted, but success was eventually obtained. In this procedure, a total of 2900 bags of portland cement was consumed. When the grout had hardened in the crevices, a few more holes were drilled, and water having a head of 65 lb. was found 14 ft. below. These holes were soon grouted up, only 60 bags of cement being required.

Sinking was not at once resumed, however. It was deemed advisable to deal further with the question of the water. The Shawangunk grit was now about 100 ft. further down, and it was proposed to grout up the intervening water-bearing strata. Accordingly, six diamond-drill holes were put down to the grit; half were of the size corresponding to a 1-in. core; and half corresponding to a 2-in. core. With a pressure of 275 lb. per sq.in., these holes were grouted up with 175 bags of cement. No one knew whether the small quantity of grout required meant that the problem was a small one or that it had been only partially solved. It would seem that a thorough application of the method of grouting ahead of the excavation should have been employed sooner; that is, before the water-bearing strata had been penetrated.



Emergency Pumping Plant at 300-ft. Level

Emergency Pumping Plant

Sinking was now begun again, and prosecuted until a depth of 320 ft. was reached. Several collecting rings had been arranged, and a number of sinking pumps installed in the shaft. The working space was much restricted and, moreover, it was difficult to secure easy, certain and adequate pumping capacity by the use of sinking pumps alone. It was determined to construct a pumping chamber off to one side at the 309-ft. level. This chamber was made quite large; 10 ft. high and 17x24 ft. in horizontal dimensions. Beneath its floor was provided a sump 5½ ft. deep and 16x22 ft. in area, having a capacity of 14,500 gal. Three 24x10x20-in. horizontal condensing pumps with a combined capacity of 1050 gal. per min., furnished by the Cameron Pump Works, New York, were installed in the special chamber and supplied with steam by three 100-hp. boilers set up at the mouth of the shaft. This arrangement was greatly facilitated by using pumps of the condensing type.

Before the installation of this powerful pumping plant was complete the sixth flooding of the shaft took place. Subsequently, no especial difficulty was encountered in connection with the water. More grouting was done, but, with one exception, none of the seams required more than 100 bags of cement. When the grit was reached, one hole gave trouble and required 348 bags of cement to stop the flow. The amount of water pumped from this shaft was 86,181,000,000 ft.-gal., and the total amount of portland cement consumed in the grouting operations was 971 barrels.

Use of Grout in Shaft Sinking

R. C. Johnson calls attention to an error made in publishing his article "Use of Grout in Shaft Sinking," in Coal Age of Feb. 24. On page 641 the phrase reading "200 gal. of water per hour" should be "200 gal. per minute." It will be noted that this puts a somewhat more favorable aspect on the possibilities of the scheme in question.

In order to avoid accidents, drivers should ride on the front end of cars on a downgrade. The practice of riding between cars should be prohibited, also the dangerous habit of sitting on front bumpers and allowing the feet to drag over the rails.

Another Explosion Test at Bruceton

Editorial Correspondence

This most recent experiment conducted by the engineers of the Bureau of Mines resulted in furnishing quite satisfactory proof that a stonedust barrier will stifle the flame of an explosion and prevent disaster spreading through the entire workings of a mine. Also interesting notes on flame velocity and maximum explosion pressure.

On Saturday, Feb. 24, at noon, the Bureau of Mines conducted an experimental dust explosion in the federal mine at Bruceton, Penn. The arrangements for the test were under the direction of Chief Engineer George S. Rice. The mine was exploded without mishap or delay and the results were gratifying.

At 7:30 o'clock Saturday morning, the government engineers, accompanied by invited guests, left Pittsburg on a Baltimore and Ohio train arriving at the mine, 14 miles out of the city, before 9 o'clock. The forenoon was spent by those present in examining the mine and observing the arrangement of the experimental recording machines. Every detail of the preliminary preparation was carefully explained by the representatives of the mining bureau.

Steel Gallery in the Foreground. The Smaller House on the Right Near Side Portal Shelters Fan and Is Uninjured. A Body of Flame and Smoke is Seen Escaping from Main Portal in Rear

The accompanying sketch shows a rough plan of the mine and the location of the seven recording stations. The first two stations which are shown on the left side of the main entry looking into the mine, have been practically completed and are larger and better equipped than the other five stations located on the right side of this same main entry.

The Recording Instruments

The principal data sought by the Bureau of Mines were the flame speed, and the maximum pressure of the explosion. In order to determine the velocity of the flame, each station is equipped with a circuit-breaker, consisting of a strip of tin foil, which latter is so arranged that it is readily melted by the heat of the explosion. After the tin foil is melted and the circuit is broken, a commutator switch comes into play, and a mark is recorded on a chronograph located in the recording station just above the mine and about 800 ft. distant.

The records of pressure are secured by means of a crusher manometer, which instrument has been adapted from similar instruments that are now used by the U. S. Navy in determining the maximum pressure of big guns. These manometers are also connected with the magnet of a recording chronograph.

The chief defect in the system, as at present arranged, is that the testing apparatus situated in each of the seven stations, is so connected in series that in case one of the stations fails to record,

all the remaining stations on the way out also fail to furnish a record. It seems that this can be avoided and I understand it is the intention of the Bureau engineers to remedy this fault by having a separate chronograph for each station, or by having the drum on the chronograph wide enough so that an individual record for each station can be secured.

Gas Samplers

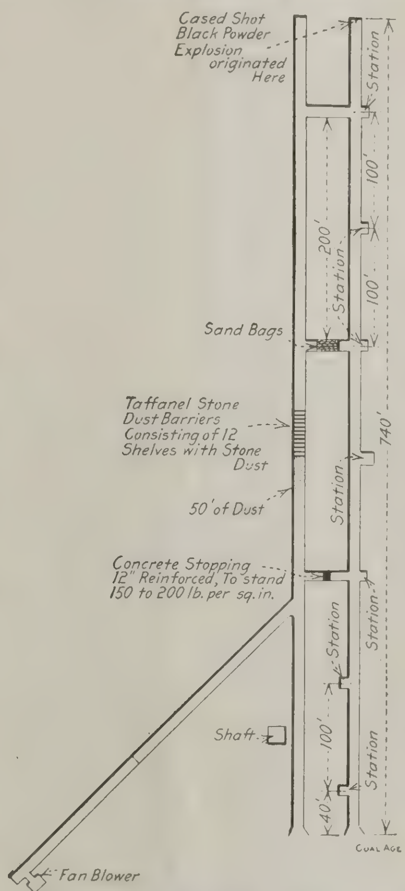
In addition to the recording instruments just described, the mine was equipped with a British coal gas sampler, and two gas samplers built in the experimental station at Pittsburg. The principle on which all these gas collectors work is based on the suction idea, and is expected to furnish the experimenters with a true sample of the afterdamp that follows an explosion.

The gas sampler built by Mr. Burrell at the Pittsburg station, is a simple apparatus consisting of a gas cylinder identical with those fitted on oxygen breathing apparatus, and supplied with a glass bottle and an automatic valve. The gas cylinder is so arranged that a vacuum exists inside and the force of the explosion as it passes, breaks the glass bottle fitted to one end of the cylinder, afterdamp rushes into the tank, automatically closing a valve and thereby confining itself. These samples are only in the experimental stage and as yet have not been perfected or proved.

J. W. Boileau, Coal Expert, and A. C. Beeson, Chief Engineer Pittsburg-Buffalo Co., Getting a Handout After the Explosion

The Stone-dust Barrier

Possibly the most interesting result of this test was the action of the Taffanel stone-dust barrier that was located on the airway between the first and second crosscuts. (See sketch.) This barrier consisted of twelve shelves, on which stone-dust was piled. It is a fact that when the explosion occurred, no flame was seen to escape from the steel gallery that leads off from the air course to the fan. The accompanying photograph of the explosion, is rather convincing proof that the barrier stopped the flame. Practically no smoke is coming from the steel gallery while the smoke, dust and gas is seen belching from the mouth of the main entry. An examination after the explosion had occurred showed that the coal dust just inside the stone-dust barrier had been coked and that the dust placed on the outbye side of the barrier showed no signs of having been fired.



Rough Plan of Bruceton Mine, Showing Location of Recording Stations, Stone-dust Barrier and Concrete Stopping

This is not certain proof of the efficiency of the stone-dust barrier, but is fairly good evidence that stone dust may be useful in preventing the spread of a dust explosion.

The sand bags, placed in the second crosscut, were partly dislodged. The 12-in., reinforced-concrete stopping, located in the first crosscut, and designed to withstand a pressure of from 150 to 200 lb. per sq.in., was not injured. However, a stopping of this type and having no greater width, we believe could hardly withstand the pressure accompanying an explosion originating in a large mine and traveling a longer distance.

In the explosion set off at this same mine last fall, only 1 lb. of coal dust was used for each lineal foot of entry length. In this most recent test, 2 lb. of coal dust were used in each foot of entry charged. It is evident, therefore, that in this latter case, the coal dust was in considerable excess and that is a probable reason why there was so little flame emitted from the mouth of the main entry.

Results Obtained

It is the purpose of the Bureau of Mines to issue a bulletin giving the results of observations obtained at the test. In advance of final and complete information, we are permitted to say that the recording instruments showed a probable pressure of from 150 to 200 lb. per sq.in. The flame velocity was approximately 2000 ft. per sec. Only 4 of the stations recorded.

That this test was directed along proper lines and is a step in the direction that will net valuable results, no observer present at the explosion can doubt. Personally, I was most interested in the action of the stone-dust barrier. I feel sure that if I was in charge of a dangerous mine tomorrow, I would install stone-dust barriers at selected points, without waiting for any more definite results.

Snapshot of J. A. Holmes—Taken at the Instant the Switch Was Thrown in to Fire the Shot at Coal Face

The flame velocity and especially the maximum explosion pressure are good things to know so that we can properly gage the size and strength of air-stoppings; however, next to the seemingly satisfactory action of the stone-dust barrier, the matter of greatest interest was the change in the amount of coal dust used, and the altered character of the explosion. I did not see the first explosion, but am told that this initial test showed more flame, undoubtedly due to the fact that the coal dust present (1 lb. per lineal ft.) was nearer the maximum explosive limit.

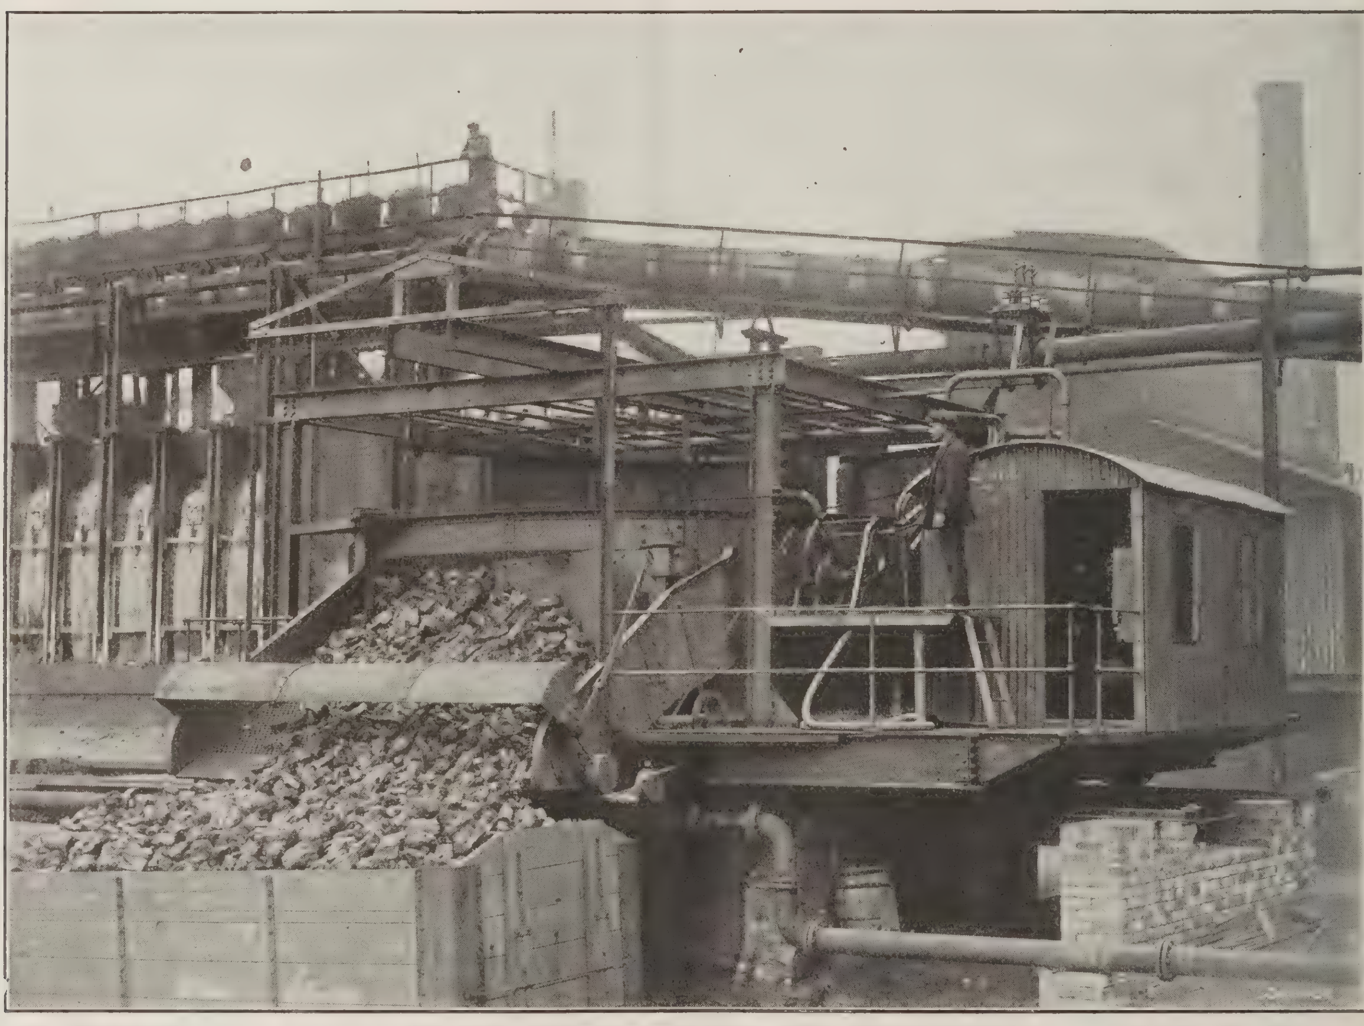
A Retort Coke Quencher and Loader

By A. Goodall*

Description of an apparatus for quenching and loading coke from retort ovens in one operation. A number of plants are in successful operation in England and it is claimed the machine will effect a considerable economy in labor.

For many years efforts have been made to reduce the cost of handling coke as discharged from retort coke ovens. Various forms of benchwork have been devised, and several kinds of mechanical apparatus tried.

The problem is not altogether easy, because of the variety of conditions to be met. The coke must be quenched as it leaves the ovens, or it will damage the railway cars, but it must not be quenched to such an extent that it contains a large percentage of moisture. The breeze and small must be removed before loading, and there must be facilities for loading anywhere along the entire length of the bench, or beyond if required.



Machine Discharging Coke in Railroad Cars

The problem would be simplified if a car could always be placed opposite the particular oven to be discharged. This cannot be done in the ordinary course of working without much cost and inconvenience. Goodall's Patent Coke Quenching, Screening and Loading Machine has been designed to meet all these conditions, and in practice shows a saving of quite two-thirds of the labor usually expended in performing the same operations by other methods.

*2105 Tioga St., Philadelphia, Penn.

Description of the Machine

The machine consists of a large frame running on wheels on rails placed in the position usually occupied by the bench or quenching floor. The frame carries the motor and gearing to propel the machine along the rails in either direction and to revolve the table and drive the shaking screen. On the center of the frame there is a footstep bearing, and at a reasonable diameter a ring of rollers for carrying a revolving horizontal table, which is of stong construction, and covered with cast-iron perforated plates.

This table is surrounded with a ring of plates fixed to the frame and having cast-iron lining plates which are renewable. There is a slot or opening with guide plates, in this ring opposite the center for guiding the coke on to the table; this is of cast-iron and so constructed as to form a quenching box or hood. This box has slots in the sides through which the water from perforated pipes sprays on to the hot coke, as it leaves the oven and before it reaches the revolving table.

Directly opposite this opening, there is a large door in the casing. This door is controlled by a winch in such a manner, that when the door is closed the inside of the casing is a complete ring, but when opened, the door projects inwards and acts as a scraper or ejecter in removing the coke from the table as the table is revolved. The *modus*

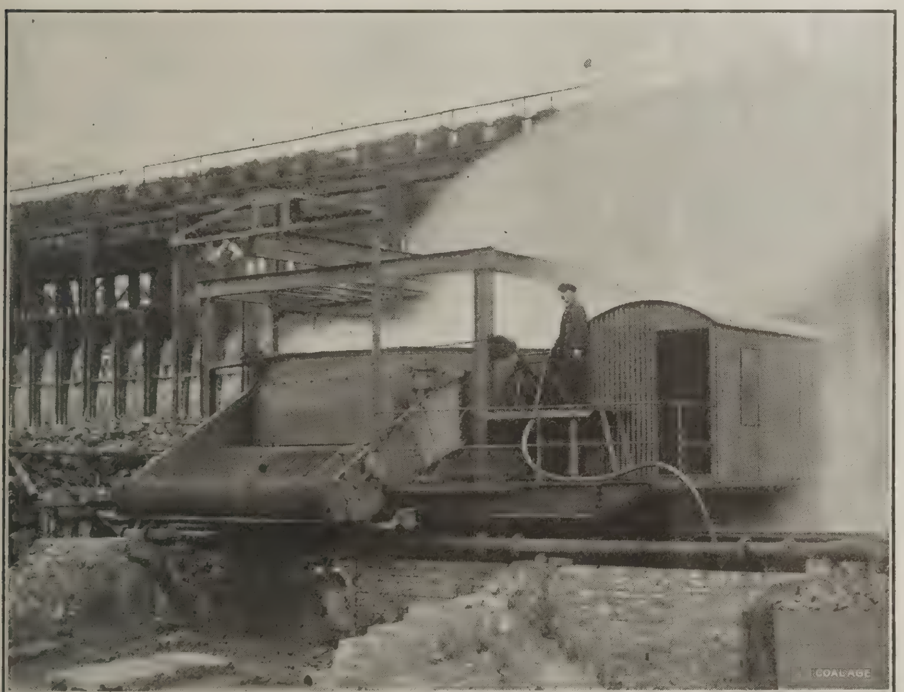
operandi is clearly shown in the accompanying sketch, which shows the door open ready to discharge the coke.

Construction of Machine

Under this opening, or doorway is arranged a shaking screen, fixed at such a working slope that the coke as it is ejected from the table, is effectively screened, and passes therefrom into the car. A receptable or hopper below the screen receives the screenings and can be emptied into the breeze car as required. Moreover the breeze can be further separated from the small, where there is a sale for such. In addition to the quenching hood, there is arranged above the revolving table, pipes to further quench the coke as it lays on the table and a small hose for spraying any odd pieces of hot coke, is also provided, thus ensuring the coke being properly and effectively quenched.

The revolving table is constructed of mild steel girders thoroughly braced and riveted together and carrying perforated cast-iron floor plates. The mild steel plates forming the case round the outside of the revolving table are lined with cast-iron plates so that with the exception of the screen plates all the wearing surface which comes into contace with the coke is of cast-iron.

The machine is driven by a 20-hp. motor, or it can, if required be fitted with a steam engine and boiler where electric power is not available. The different speeds for propelling the machine along the track, the revolving of the table, and the operating of the screen are obtained by worm- and spur-gearing all enclosed in suitable gear boxes, the main gearing being steel and mostly machine-cut. The travelling wheels are manganese steel and are in pairs on the Bogie principle, two of these being driven direct by means of spur-gearing. The whole of the gearing and opening platform is enclosed in a corrugated iron cabin and the machine is fully equipped with switches for power and light, lightning arrestors, controller, resistance, etc., for the proper and economical working during all hours. From tests that have been made, it has been found that the power required to deal with a charge of 7 tons of coke, was equal to 2.52 kilowatt-hours.



Quenching the Coke Preparatory to Loading

Method of Working

The method of working the machine is as follows. The machine is propelled along the rails, and the slot or quenching hood is brought opposite the oven to be discharged. The oven door is now removed and the pushing of the oven commences. When the nose or front part of the cake of coke has entered the quenching hood, the valve controlling the water supply to the hood is opened, and the water sprays on both sides and the top of the coke, during the time it is travelling through the hood. In the meantime, as soon as the coke has entered on the table a short distance, it is revolved, and by this revolving of the table, the bottom part of the coke is carried away as it were, and gently and evenly distributed over the table.

The coke if required, can be further quenched by means of the perforated pipes above the table. Immediately the ram or pushing rod is withdrawn, the machine is removed from the front of the oven to allow the oven door to be reset and the oven to be recharged without waste of time and loss of heat. After a reasonable time for steaming and drying, the coke is ready for loading into cars. All surplus water and dirt drains away immediately through the perforations in the floor plates of table, and so avoids over saturation of the coke.

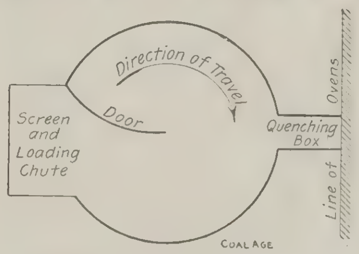
The machine is now propelled to the car, or other receptable which requires loading, either along the front or beyond the battery of ovens. The table is revolved in the required direction and the discharging door or ejector operated by the hand winch, by which means the coke is gradually fed on to the screen, and so on into the car. The small coke is received in a hopper under the screen which is emptied into a car placed in any convenient position, as required.

Operating Costs.

The same operation is repeated, as the ovens are burnt off and it has been found by practice, that one machine can effectively deal with 60 ovens and that the coke is put into cars in the best marketable condition.

These machines are in successful operation at a number of large plants in England.

The cost of operating the first machine installed as against handling the coke



Method of Operating

by the usual methods, at the Weardale Steel, Coal & Coke Co.'s plant at Spennymoor, England was 3.88c. against 15.23c. per ton; these figures are the average obtained from about 7 months operation. The cost of repairs to three of the Weardale Co.'s machines during a period of four weeks where 14,000 tons of coke were handled was $28.43 which includes both labor and material.

These come out most favorable owing to the plain and simple construction, and the few moving parts which are also of slow motion, large in size and heavy in design.

Further in the case of new ovens, a great deal of costly work in the building of the quenching floors, can be saved by the use of this machine. Indeed it might well be, that the saving in the floor alone would pay for the machine in new installations. There is also the advantage that the whole of the quenching, screening and loading is carried out at one operation.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Tests for Carbon Dioxide

The following is an extract of a paper written by T. Bryson for the *Colliery Guardian,* of London, England:

"For the estimation of carbon dioxide little or no knowledge of chemistry is required, when a suitable method of analysis is adopted. The principle of the usual methods is that of producing carbonates by the action of carbon dioxide on the hydroxides of alkali metals.

"The formation of carbonates by the action of carbon dioxide upon the hydroxides may be illustrated by the following equations:

$$2\,KOH + CO_2 = K_2CO_3 + H_2O.$$
$$Ca\,(OH)_2 + CO_2 = CaCO_3 + H_2O.$$
$$Ba\,(OH)_2 + CO_2 = BaCO_3 + H_2O.$$

"The first of these changes is the one that takes place when carbon dioxide is

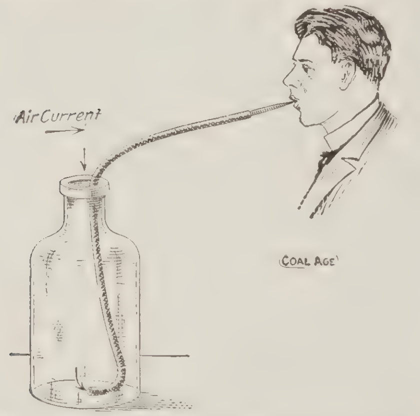


Fig. 1. Filling Bottle for Angus Smith Carbon-dioxide Test

absorbed by potassium hydroxide in such appliances as Dr. Haldane's, Hempel's, Orsat's and Bunte's. The second is the change which takes place in Dr. Angus Smith's apparatus when CO_2 is absorbed by a decinormal solution of lime water, and the third equation illustrates the change which takes place when mine air containing carbon dioxide is passed through a solution of barium hydroxide, as in Lunge's apparatus.

"Any of the above methods may be adopted for the estimation of CO_2, but since the form of an apparatus and the space occupied by it are of such importance in mining, several of the appliances are only suitable for laboratory purposes, and only a few are of any use underground.

"In mining it is not absolutely necessary that carbon dioxide should be estimated to a great degree of accuracy, and, consequently, an apparatus such as Dr. Angus Smith's may be used.

"The outfit required for this test consists of one 8-oz. ground-glass stoppered bottle, one 5-oz. ditto, four ½-oz. bottles with corks, one ½-oz. pipette, and a hand bellows or piece of rubber tubing for taking samples of air. A supply of lime water of decinormal strength, colored by the addition of a little of some suitable end-point indicator, completes the outfit.

"To make a test the small bottles are filled with the colored solution, and a sample of mine air is charged into the 8-oz. bottle, by means of the hand bellows, or sucked into the bottle by the observer, who uses the rubber tubing in the manner shown in Fig. 1.

"When the sample has been obtained the contents of one small ½-oz. bottle is emptied carefully into the bottle containing the air to be tested. If the solution is decolorized, the air in the bottle contains over ¼ per cent. of CO_2. By using all four bottles of lime water, an approximate test up to 1 per cent. may be made, and, fortunately, this number is rarely exceeded in testing air from mines of today.

"Lunge's test is one by which a much closer approximation to the actual amount of carbon dioxide in the air may be obtained, and it requires a person using it to have a little more knowledge of physics and chemistry than the last test, but nothing more than is usually obtained by attendance in a class in physics and chemistry of mining.

"Fig. 2 illustrates the apparatus, which consists of a rubber bulb of known volume (= 60 cc.), and a 5-oz. bottle with the necessary fittings of tubes and cork. The solution, in this case, is a decinormal solution of barium hydroxide, to which are added a few drops of phenolpthalein, for the purpose of indicating the end-point in the reaction between the CO_2 and the $Ba\,(OH)_2$.

"To prepare the apparatus for the test, 48 cc. of distilled water and 2 cc. of decinormal $Ba\,(OH)_2$ are put into the bottle, the bulb is compressed and the cork adjusted. The bulb is now allowed to fill and then it is slowly compressed to pass the air being tested through the solution, which becomes decolorized when the required amount of CO_2 has been passed through. The number of compressions are noted, so that the volume of air can be calculated. To neutralize the $Ba\,(OH)_2$, according to the law of definite proportions and the equation already stated, 0.0091 gram of CO_2 will be required. The volume of this weight of CO_2 is calculated at normal pressure and temperature and corrected for changes of pressure and temperature, after which the percentage of CO_2 in the air being tested

$$= \frac{\text{volume of } CO_2}{\text{volume of air}} \times 100$$

In examining the air of a particular mine periodically, there will be no need to make the slightest calculation after, say, three or four tests have been made and the results plotted in square paper. It would only be necessary to note the number of compressions required and consult the graph to obtain the percentage of CO_2."

For those whose knowledge of analytical chemistry is slight, it may be stated that a normal strength of lime water is 28 grams of lime (CaO) per liter, whereas a barium hydroxide solution of normal

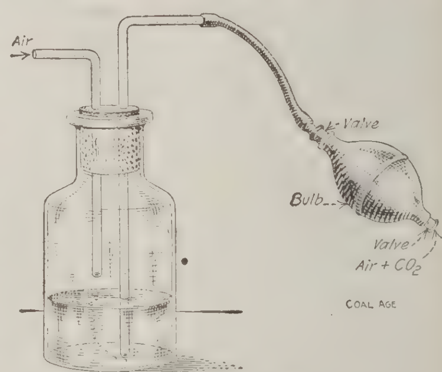

Fig. 2. Passing Measured Air Into Bottle—Lunge Test

strength would contain 85.7 grams of the metallic alkali per liter. Decinormal solutions would, of course, be one-tenth as strongly concentrated. The end-point indicator is a chemical which will change its color when the solution in which it is dissolved changes its condition from alkalinity to acidity, or *vice versa.*

Precautions in Dry Mines

In his annual report for 1911, George Blacker, of inspection district No. 1, Wyoming, gives the following notes on fire protection in the dry mines of that state where stoppings frequently inflame:

"A source of danger requiring attention is the careless practice, in which miners indulge, of allowing their powder cans to lie where they are exposed to naked lamps and the sparks which fly from the same. The mine foremen are

likewise blamable for this condition of affairs and should insist when hiring a miner that one of the conditions of his employment shall be that he use a box in which to keep his powder, paper and squibs. I observe with much satisfaction that in Rock Springs, all such boxes are being covered with tin, and rendered impervious to fire.

I am pleased to note a steady increase in promoting safety from fires, which in the past have wrought havoc in coal mines throughout the country. The air bridges, when constructed of wood, are being incased with sheet iron and made as nearly fireproof as possible, and the newer ones are being built of concrete."

Strong vs. Weak Stoppings

Mr. Blacker is a strong advocate of indestructible stoppings, as will be seen in the following extract. The question, however, is not so simple as he regards it. Weak stoppings allow the lateral extension of an explosion and permit the spread of the gaseous products of combustion along unforeseen channels. However, the existence of strong stoppings favors the extension of the explosion *along* the airways and leaves the ventilation unimpaired, thus the vitiated air spreads from the seat of the catastrophe as far as the current travels. It may be pointed out that where the explosive violence is not hedged in by strong stoppings on either side, the force of it is reduced, the coal dust on which it feeds tends to fall and the temperature of the blast is reduced by the large quantities of cool air with which it is admixed. Thus the travel of the explosion is shortened. The subject is an open one and the following note expresses Mr. Blacker's convictions on the matter:

"It is high time that the antiquated methods heretofore employed in the building of stoppings with common boards, wood blocks, boney, brick and stone, or any material which will burn or be blown out, be abandoned, and that modern methods be applied which are free from any of these objections. An explosion is rarely general, that is, its force rarely extends to all sections of the mine, then why is it that the miners working in that portion of the mine which is not affected by the force of the explosion, are suffocated? Is it not because the stoppings are too frail to withstand the force of the explosion and are therefore blown out, and before they can be rebuilt, even temporarily, and the current partially restored, the deadly afterdamp like an assassin, waylays and destroys the miners This being true, as all must admit who are familiar with scenes in the mine after an explosion, then what is to be thought of the management of those who are directly in charge of such a mine, who see stoppings blown out like paper by an explosion and the deaths of scores of men far away from the point where the blast originated or extended and who nevertheless will immediately rebuild those stoppings in the same manner as formerly? Does not such an action seem like a crime?"

Explosions

Speaking on "Some Coal-dust Explosion Problems," James Ashworth, of Vancouver, Can., at a recent meeting of the South Wales Institute of Engineers, made the following remarks, which it may be anticipated will not meet with general approval, as he himself regretfully admits.

"Experiments and the demonstrated facts of colliery explosions, have led me to conclude that it is the fresh dust largely produced from the attrition of coal during transit, which is the most dangerous element in the origination and propagation of an explosion in a modern coal mine, and also that no pioneering cloud of dust is required, except to extinguish the flame. For some years I have held the opinion that this new dust, just as fast as it is produced, is floated away in its own balloon of gas; that this is its actual condition was practically demonstrated by Prof. Phillips Bedson's experiments. These proved that the gas content of each particle of coal was greater than the cubic contents of the particle, and therefore that the gas was under pressure. Consequently when exposed to the air, the coal dust more or less quickly dissipates its store.

Fresh vs. Old Dust

Again, to quote Prof. Bedson, when a particle of coal dust has exhausted its occluded gases, these are principally replaced by oxygen, because the nitrogen is filtered out by the smallness of the pores of the coal dust, and, as the resulting oxidation makes the dust heavier, it thus naturally settles on the timbers and the rough sides of the roadways of the mine. This course of reasoning brings me to the conclusion that the principal factor in a coal-dust explosion is the gas escaping from the coal dust floating in the air, while the dust itself is but a secondary cause. The dust on the roadways and the "pioneering" cloud of dust take a secondary place, and are the great source of the large volumes of carbon monoxide which are formed in every explosion of a coal mine.

There is another phase of the subject, in which I have so far had little support from other students of explosive phenomena--viz., demonstrations of detonation and percussion. At Altofts there were at least three demonstrations of enormous force, and the records published may be searched through without any explanation being found, and it would appear as if no special value has been attached to these occurrences. I refer to Nos. 13, 21 and 25. In the case of No. 13, two lengths of sectional boilers, each 15 ft. in length, were blown to pieces, the bottom parts being completely flattened out. The most important point to note is that this "burst" was not at the end of the gallery, but 60 ft. back from the end (the downcast). Experiment No. 21 produced a still more noticeable feature, viz., of an explosion within an explosion outside the end of the downcast. Why an explosion within an explosion? In experiment No. 25, three lengths of boiler shell were literally torn to pieces, and again there was the flattening of the bottom plates. The end boiler shell was not torn to pieces, and the effect was in this respect similar to No. 13. Were not all these effects demonstrations of detonation? If the force were not caused by detonation, what caused the noise to be heard at a distance of seven miles?

No Cure But Care

Assuming that it is proved that detonation or percussion may be a feature of any modern colliery explosion, it then follows that zones, whether of water or stone dust, are not of the least practical value. Watering by sprays or otherwise and dampening by steam is perfectly useless as a means to control the extension of an explosion after it is once initiated, and are only useful for sanitary purposes. I believe a dry mine to be safer in every way than a damp one, and that an excess of dust will smother out an explosive flame. The experiments which have been made for the purpose of proving that stone dust could restrict the extent of an explosion are entirely misleading to this extent, viz., that they have not been made under conditions representing a roadway in a mine where, under normal conditions, the air is carrying along its regular quota of the finest and freshest dust, and which is being continuously produced. This dust alone is calculated to carry an explosive flame over a stone-dust zone. In conclusion, as neither a stone-dust nor a watered zone can restrain a detonative or percussive effect, it follows, in my opinion, that at the present time there is no known means of controlling the extent of an explosion, except by preventing its initiation."

It might be added to Mr. Ashworth's remarks, the statement that he has for many years been of the opinion that a fall of rock could generate an explosion of coal dust simply by the air compression which it would cause. He does not regard it as necessary that the extension of an explosion shall be limited by the travel of the flame or of the heated products, but views it as possible that compression, percussion and detonation may extend the explosion from many disconnected centers.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

Nine times out of ten the character of the chip is largely determined by the soundness of the block from which it is cut. According to such reasoning, it is easy to understand why John H. Jones has sufficient business acumen to justify the Pittsburg-Buffalo company in carrying a million dollar policy on his life.

While the four Jones brothers, John, Tom, Dave and Harry, have stuck close to their knitting and not only cornered "Miss Opportunity," every chance, but handcuffed the old lady, whenever she ventured near, there's no gainsaying the fact that "Daddy" Jones, father of them all, built the body of the ship and headed her nose toward the Island of Promise. And while the old vessel wasn't an ocean greyhound, she had a steady keel and was mighty seaworthy.

Half the energy of life is wasted in not knowing which way to steer first, and the fact that the Jones boys had their compass set and their early course mapped for them, made the going a bit easier, but it shouldn't detract from their proved skill as navigators in a squally sea. Furthermore, there's a lot of people who can convert a sailing vessel into a fishing smack, but ony a few who can make a turbiner out of the same old ship.

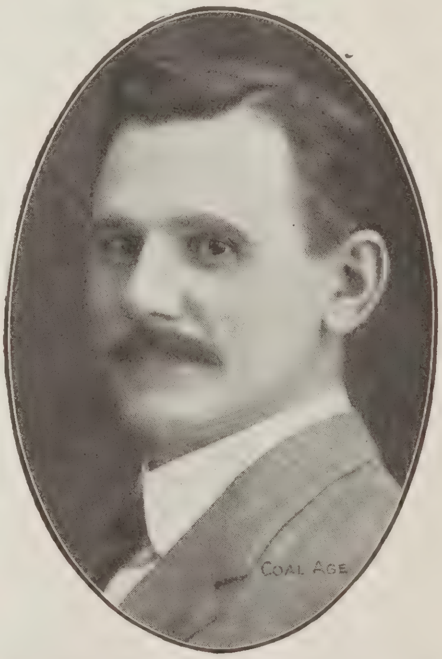
If James Jones, founder of the business success of the present family, had any two qualities o'ertopping all other virtues, they were *energy* and *perseverance*. These two attributes of character can accomplish much without talent, but the latter can do no more without them than an engine without steam. However, the elder Jones had ability as well, and the common sense to concentrate these essentials on one unwavering aim.

From that day, back in 1858, when "Daddy" Jones landed in New York, there is no evidence to prove that he knows how to go backward. Starting first at Frostburg, Md., he arrived shortly after at Pittsburg, where he secured employment as a blacksmith. This work was followed by a change to mining, which occupation was pursued until his retirement from active business a few years ago.

In the meantime, while the elder Jones had been building and enlarging his interests, John H. had busily occupied himself in making good on his own account. At 10 years of age he worked in and around the mines, and at thirteen, he left school and took charge of shipping and loading coal at his father's properties.

At sixteen, young Jones returned to school, but he was soon in harness again, and the following year filled the position of mine boss at his father's colliery. Upon the formation of the Catsburg Coal Co., by his father, John H. was elected secretary, treasurer and general manager. About this same time he went into business for himself, shipping coal to Cincinnati, New Orleans and other river points. He also secured an interest in the Rostraver, Ivill and Catsburg Coal Companies, acting as general sales agent for all these concerns while still handling his own business.

In 1896 when "Daddy" Jones consolidated with the boys, and also took over other properties, the interests of John formed no small part of the new company, and he was appointed manager of



the combined operations. In 1899, the Jones interests were sold to the Monongahela River Consolidated Coal and Coke Co., and the four Jones brothers devoted themselves to the incorporation of the Pittsburg-Buffalo Co., electing John H. president.

Mr. Jones is also president and a large stockholder of the Federal National Bank in Pittsburg. He is vice-president and director in the American Sewer Pipe Co., director in the National Fire Proofing Co., and many other financial and industrial institutions. His home life is ideal, and when the day's work is finished, you'll find John H. on his magnificent estate at Johnetta, Penn., riding a favorite horse or chumming with the kids. If I wasn't the son of my own father, I would rather be that of John H. Jones than any one else I know.

There are many sidelights on the character of this man, but three things appear to me to stand out most prominently. First, there is concentrated energy, coupled with decision and promptness of execution. Every movement indicates the man alert. When John begins to move, and that's pretty much all the time, something commences to happen. There's no fuel burned up in unnecessary switching.

A second quality that John H. has developed to overflowing measure, is tact, the open eye and very life of the five senses. It has enabled him to cut all the knots he couldn't untie, and has permitted his performing disagreeable duties after robbing them of their sting. Talent is weight, tact is momentum; the former is inherited, the latter can be acquired. In the case of our friend John, we are inclined to the belief that his pleasing manner is an acquisition of his personal getting. "Daddy" Jones was of the old school. His son is of the new type of business leader. The sort of man that causes the unsophisticated to believe that all you have got to do is to hold out your hat to him, and it will be filled with gold. But here's a tip: Don't spend any money you're going to filch from John H. Jones until you've delivered the goods, had them O.K.'d, and the coin is in the bank.

In closing this sketch, I must mention a third characteristic of our subject, and that's loyalty to a purpose or a friend. The exercise of this quality begins in his home and extends to the limits of his business. Its Tom, Dave, Harry, John H., Jr., and the whole family that Mr. Jones is plugging for, rather than for the President of the Pittsburg-Buffalo Company.

His employees are next to him in kin, and when asked what line he wants his boy to follow, you'll get one reply: "I want him to devote himself to the betterment of our men; the building of more comfortable houses; the beautifying of our mining towns and the provision of sanitary and more enjoyable surroundings." He has never forgotten the hours of labor spent underground and on the wall of his office is his fireboss certificate dated Feb. 7, 1888, and issued to him when he was 21. It's his close contact with the men and their work, that has enabled him to develop mines that are considered the model operations of this country.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

COAL AGE

Afterdamp

Not long ago, Jan. 6, we had occasion to comment on a definition recently substituted for the original meaning of black-damp. A misrepresentation of the meaning of the word "afterdamp" is almost as common. For a long time there has been a tendency to make afterdamp merely the unscientific appellation of carbon monoxide; the former word meaning if it means anything, the mine air after an explosion.

We are by no means clear what after-damp really contains. Nor will we get close to its real constituents so long as we continue to collect it for examination by pouring water out of flasks and permitting the mine air to enter in its place.

Perhaps we will never know by taking samples after a mine explosion what gases are created in such disasters. And for this reason; that it is probable, even likely, that a large portion of the gases may be soluble distillates resulting from hte heat of the blast. These dissolve with rapidity and are precipitated. One large resultant product of an explosion is water. The hydrogen of the methane unites with the oxygen of the air so that water vapor is formed. This is the vehicle through which eventually the soluble distillates will be deposited on the roof, walls and floor of the mine as soon as the temperature has been reduced sufficiently to make such an action possible.

It is probable, therefore, that he who would make such a determination must be on the ground shortly after the disaster, and the way to find the true resultants of such a conflagration is by an experiment, in laboratory or mine, the product being collected not by displacement of natural water, but of some other fluid which does not dissolve the gases—mercury for instance.

It has been suggested that by the use of two water flasks connected by a siphon, a more correct approximation might be obtained than with a single flask. By raising the sampling bottle, the water passes to the other and the first bottle is filled with air. By lowering it below the second bottle, it is filled with water and the air is expelled. These actions frequently repeated will saturate the water with soluble gases, and if the temperature and pressure of the water is not changed, this fully saturated fluid will permit eventually of the taking of a sample of air, which will represent the more soluble constituents of the air as well as the less soluble. But this process is slow, time presses in taking such a sample and perhaps a non-absorbent liquid would serve the purpose better.

It has been noted that water dissolves and glass absorbs carbon monoxide. We may overlook these absorbencies, but not the solubilities of ammonia, hydric sulphide, sulphur and carbon dioxides and nitrous oxide. K. B. Lehmann states that exposure to 0.25 to 0.45 per cent. of ammonia causes illness and danger to life in from a half hour to an hour; 0.1 to 0.2 per cent. of hydrogen sulphide causes rapid death, while 0.05 to 0.07 per cent. will cause illness and possible death within an hour; 0.04 to 0.05 per cent. of sulphur dioxide is equally distressing within a like period. These bodies are very soluble in water. At the temperature of the mines, water will dissolve about 1000 volumes of ammonia, four volumes of hydric sulphide, 67 volumes of sulphur dioxide, 1½ volumes of carbon dioxide and one volume of nitrous oxide.

From these statements it will be seen that highly important gases may exist in afterdamp outside of what are commonly called higher hydrocarbons, and these are not unlikely to evade collection by the current methods. The higher hydrocarbons, and perhaps the bisulphide of carbon, are possibly other causes of toxic action.

Afterdamp is sometimes termed "choke-damp", because it causes choking. This spasm of the windpipe is probably due to the presence of other gases than the monoxide and dioxide of carbon.

We are told that a wet rag is of avail to keep out afterdamp, yet there has been published in Coal Age an article (Dec. 23, 1911) to show of what little avail it may be in keeping back the simpler compounds of carbon. At best, the rag would absorb its fill of carbon dioxide in 3½ sec. and its possible monoxide retent in less than one second. Nevertheless it is generally thought that the wet rag is of value. Perhaps the reason for its efficiency is to be found in the fact that among the compounds it excludes may be unrecognized bodies of highly dangerous character and great solubility.

In a recent article, Edwin A. Chance (Jan. 27) said that: "A case has been reported in which several men lost their lives on entering an atmosphere containing 0.0023 per cent. of monoxide and 4.874 per cent. of carbon dioxide. The oxygen percentage was not stated." He ascribes their death to the combined effect of the two gases. Would it be unreasonable to inquire whether it was not due to a third or to a combination of many toxic gases? In fact, if the gas was collected as Mr. Chance advocates in our issue of Dec. 30, what chance was there that any higher soluble gases would be apparent in the analysis, which by the way appears to have been a somewhat incomplete one?

If we continue to have faith in the dampened rag and conclude that explosion products have the contents generally claimed, then indeed we must assume a "dialysing" action in the wet rag, or that the rag caused a remarkable reduction in breathing, or that some other action existed, the nature of which all orthodox chemists will deny.

We would not be dogmatic and assert that the arguments given are absolutely conclusive, but they open a field for investigation and bid us beware of thinking that the true afterdamp is the insoluble residue of the air after an explosion.

Coal Dust Heterodoxies

We print this week in our Current Coal Literature, the interesting remarks of James Ashworth, on the explosion of coal dust. And this we do because we are advocates of an open forum, because no shade of opinion which might conceivably be right should be supressed by any public organ till that opinion has been heard and duly weighed.

There is little need to decry the gaseous skin or pellicle theory which Mr. Ashworth restates, because this theory of the cause of an explosion was discussed in full in our editorial on "Methane in Coal Dust Explosions," contained in the issue of Feb. 17. What little show of validity may possibly clothe this consideration is of little use in assisting to bolster up a detonation theory, with which he concludes his remarks, and perhaps Mr. Ashworth regards the two alleged phenomena as without bearing, the one on the other. If coal dust can be detonated, what need is there to show the presence of a methanized envelope around each particle?

But, perhaps, it might be well, here and now, to point out that if a skin coat of gas is to be found on every particle of recently formed coal dust, and if that coat is the cause of dust explosions, then why is it that flour and lycopodium ignite with such explosive violence? Are these also enveloped in like pellicles of explosive gas?

The pellicle theory, here held to be a heterodoxy, is of different character to that theory largely, and we believe not unreasonably, held: That all solid hydrocarbons—coal, cotton, flour or lycopodium—are not in themselves explosive and that the gas alone given off by them when they are exposed to heat is the source of the violence which accompanies combustion. This is another proposition, a hard one to combat and a hard one to prove; with it we have no quarrel and for it no valid defense. At present writing it is a theory unproved but inherently likely.

The theory of detonation advanced by Mr. Ashworth is interesting and doubtless original with him. It has been found that detonating substances contain within them enough or almost enough of such elements as would permit of complete internal combustion. Detonation causes an atomic loosening, whereby elements contained in the unstable compound are freed instantaneously. They are then able to combine at once with other elements, also just freed, the mutually attracted elements being intimately disseminated within the detonating body. But Mr. Ashworth says that coal dust detonates. We do not believe that he is of the opinion that a molecular rearrangement takes place *within* the coal particles, but that molecular combinations take place with the external air of such a violent nature that "detonation" will rightly be applied to them. An internal detonation could not be the result of combination with oxygen, the most usual action of detonating bodies, because within the coal particle not much oxygen is to be found. Moreover, Mr. Ashworth is of the opinion, as are most theorizers, that stale dust, though more thoroughly impregnated with oxygen, is less explosive than the dust which is fresh. We do not know the nature of the detonation he would hypothecate. Whichever it may be, there may be such a detonation, but probabilities do not favor it.

Such unstable theories are used by Mr. Ashworth to back his statement that sprinkling and the use of steam are alike of no value. An assumption such as this, hard as it is to prove true, should not be permitted to sweep aside clear knowledge that moistening is of advantage. We are not clear, however, to what extent moistening can be perfected nor are we sure of the scope of its ability to immunize, but that it is of value and to be pursued in all mines where the temperature is not excessive and the roof not affected, is our firm and unwavering conviction.

The Death Toll of Mining

We have to dig so many million tons of coal every year to keep our mills and factories running, to heat and light our houses, to drive our locomotives and serve base culinary ends. And in that digging and extracting some lives are lost. The fewer lost the better, but the coal must be won. And so we think that the more tons we can win for each poor unfortunate killed or maimed, the more happy we should be. It would, therefore, seem that we should look with disfavor on the making of comparisons by percentages of men employed. If tomorrow a sufficient amount of coal could be mined by half the usual number of men, though the maimings and killings per employed man were raised a few per cent. by the exchange, we would have cause to rejoice, because the army of slain would be all but divided in two. We could not reasonably repine because by an erratic method of reasoning the percentage of slain had risen a few tenths.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Three Mining Questions

In reading COAL AGE, each week, I have been much impressed with the way it brings us in touch with practical mining men—I think, more so than any mining paper or book I have ever read. It is interesting and what we want. There are three questions or matters to which I would like to refer; they are as follows:

Controlling or Preventing a Mine Squeeze

A mine adjoining ours had, at one time, a squeeze. We knew nothing of this till some of our rooms drove up and broke through into their old works. Now, our rooms are falling in on an entry close by; these rooms are "on ribs" (drawing pillars).

I should say our mine is worked in coke-region style, leaving 10 in. of roof coal up to support the drawslate, which overlies the coal and is soft and brittle.

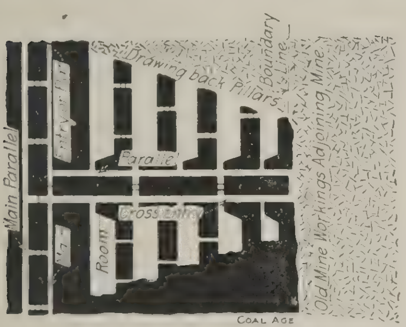

FIG. 1. PILLAR WORKINGS AFFECTED BY SQUEEZE. ROOMS IN SOLID COAL.

The coal is underlaid with 3 in. of slate, beneath which is 6 in. of fireclay. In the rooms "on ribs," the posts were set on the slate floor; but after starting the ribs (drawing pillars), the posts sunk through the slate and clay to solid bottom. The bottom, in the roadways, heaved; the caps above the posts were broken and the rooms squeezed. Cross-bars that were set to hold the roof were quickly broken.

A section of our mine is shown in Fig. 1, and the old workings of the adjoining mine on the right. Where the squeeze was first heavily felt was in the rib workings of the rooms driven off the parallel. As shown in Fig. 1, there were rooms, at that time, being driven off the cross-entry; and I thought to stop these rooms on the entry until the ribs of the rooms on the parallel were all out. Would this be wise, or is there any way by which I can save this coal? I did not like to stop the rooms unless it was absolutely necessary, as I am short of places.

I would appreciate any suggestions that would show a way to get out this coal without a large expense. Should the line of fracture (line of pillar workings) be, as shown in Fig. 1, against the heading, or should it lead away from it? I have my own idea in regard to preventing or stopping a squeeze, but would be glad to hear how others would do the same.

Electric Pump in Mine

I have a pump run by electricity. The pump is located in the mine 1200 ft. from the water, and discharged through a pipe line 2000 ft. to the surface; 2-in. pipe being used for both suction and discharge. It is necessary to run this pump night and day to handle the water. Would it be wise, as I could easily make the change, to use a 3-in. pipe line and set the pump nearer the water? Let someone answer.

The Fireboss Question

The new bituminous-mine law (Art. 5, Sec. 1) seems to indicate that the firebosses at any mine or in any portion of a mine may be taken off and not employed, provided there has no gas been found in such mine or portion thereof for one year previous to the law being passed, or a year after.

I wonder if those who made this law thought that gas was the only danger that had to be provided for. I consider a nongaseous mine, having a shallow cover or depth below the surface, which has allowed the gas to escape as fast as generated, is often a dangerous mine and liable to dust explosion or heavy roof-falls. Such mines, though containing little or no gas, should be as carefully examined by a fireboss as the mine where gas has been found "in sufficient quantities to be detected by an approved safety lamp"; and it is important to do this before men are allowed to enter the mine, each shift.

T. E. RICHARDS.

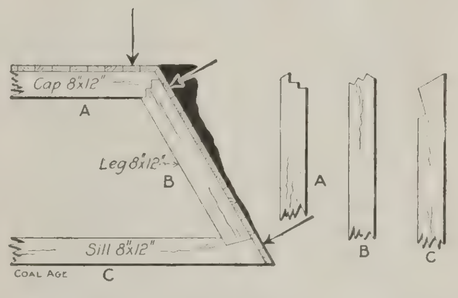
Pittsburg Coal Co., Brownsville, Penn.

[Art. 5, Sec. 1, of the bituminous mine law, requires the mine foreman to employ a fireboss, in any mine or portion of a mine in which explosive gas has been generated within one year previous or shall be generated after the passage of the act, in quantities, etc. The requirement applies to all mines or parts of mines that have generated gas, *at any time*, from a year previous to the passage of the act and is unlimited in its continuance.—EDITOR.]

Timbering for Side Pressures

Referring to the recent letters on timbering for side pressures, I wish to state that I have given mine timbering my careful attention for over 30 years, and that this problem is a hard one to solve. The accompanying sketch shows a method I have found to give excellent results and good service when properly set.

The sill, cap and legs should be cut so that all parts will have an equal bearing, and the timber can be cut for any degree of inclination of the posts desired. The arrows indicate the points at which the timbers should be blocked for the purpose of taking the first weight; timbers should not be blocked in the center, since that is the weakest point.



The improper setting of timbers is the most expensive piece of work in the mine; it not only endangers the lives of the men and shortens the life of the timbers set, but also makes the cost double, since it usually has to be immediately replaced. After the timber is in place it should be given some attention, especially up to the time it has taken the full weight expected for it. Some slight weakness often develops at this time, which can be easily and cheaply remedied by giving it prompt attention.

Derwent, Ohio. J. W. Q. MILLER.

The Mine Foreman's Trouble

I believe "The Foreman's Trouble," as given in COAL AGE, Dec. 23, 1911, p. 354, is hardly fair to the manager or operator of mines. The statement is made that the operator reminds the superintendent at every opportunity that he must keep down expenses. This is the most natural thing for an operator or manager to do.

Imagine for a moment the manager

sitting in his office twenty or a hundred miles from the works for the earnings of which he is held accountable, and the bills for supplies piling up before him and more requisitions coming in daily for more material, some of which he cannot imagine why or where it is needed; and here comes a rush order for some special high-priced oil to be rushed to the mines at once, while his records show that enough oil has been purchased to last a month longer. He wonders how they find room to set the posts that last month's records show were used; and why enough lumber or material is charged for stoppings to build four times the number the last survey showed would be necessary; and how enough iron rails were purchased to lay more tracks than they have in use.

He figures a little and finds that the pit-car oil used the last month amounts to one quart for each car dumped, and here is a letter saying that they are out and inclosing a requisition for more oil.

Reports show more troubles: Machinery broken down, boilers blistered or bulged, pumps out of order, etc. In the mine, several places are reported drowned out; the daily output or production of coal decreases, the cost of labor goes up. The drivers average 30 cars a day, while the length of their haul shows they should easily handle 50 cars. Twenty-five per cent. of the stock is reported disabled and not working; and a requisition asks for two more mules to take the place of those disabled. The bills for supplies are for iron, lumber, machinery, pipes, pumps, buckles, nails, fuse, rubber and duplicate parts of engines; yet with all these supplied the output is 200 tons a day less than should be expected; and it appears to this manager that the trouble lies with the mine superintendent or foreman.

The review of the last month's accounts decides the manager that he must take up the matter vigorously with the superintendent. A few cold facts are dictated and that official is informed briefly that "expenses are too high, and that he must get busy and either reduce his expenses or put out more coal."

The superintendent orders the mine foreman, master mechanic and other bosses, depending on the size of the plant, to lay off any spare men and economize in every way as much as possible. The men in charge may be competent men; the mine foreman and superintendent may have each established a record and proved their ability with other companies, and the manager, being a shrewd business man, is confident they can make good. Still, with all this, the results obtained do not show adequate efficiency in the management of the mine.

The foregoing is not an unusual case, and the blame may rest equally on all concerned in the management, yet each one generally thinks he is doing his duty, and the blame is on the other fellow. I would suggest, first of all, that much good may be accomplished by starting at the lower end and striving to increase the efficiency of each man; having a direct talk with each one and with each and all of the bosses and assistant foremen, separately; and urging the boss driver to enlist his men in an effort to increase the output of coal.

Mr. Mining Engineer, consult with the inside foreman, and mix his practical ideas with your theory; they will generally mix to some extent, and a sensible, broad-minded foreman may help you to secure better results where local conditions necessitate a change, and the cost of haulage, pumping and ventilation in the mine will be reduced. Helped by your suggestions, he will have more confidence in himself, take more interest in his work, and be more loyal to you than if you ignore him, and give him to understand that he plays about fourth fiddle, and that he is only employed to fulfill the law's requirements and that you may be able to lay the blame on someone else if the inspector should complain about the condition of the mine. Remember, *it is easy to establish confidence, and likewise easy to destroy the confidence of the men in your charge.*

Harmony and coöperation on the part of all, in a mine, will do more good than a sackful of orders and complaints from the head office, when that office does not know why the results are poor, except as calculated from a mass of figures and reports often changed so as to convey an idea different from what really exists.

Better all get together and consult as to where the real trouble lies, and be ready, each one, to see some fault of his own that was laid to another. How often have we all passed by work that, while it belonged to another to perform, we could have done it ourselves and by so doing have helped to improve conditions and reduce expense and waste. For instance, a laborer may be sent to level off a pile of dirt, and in doing this he covers up some good material, possibly a good carwheel, or pipe, or piece of iron, because he was not told to move them. If you see it, have him move them, or do it for him, yourself. The carpenter or blacksmith, or any better-paid man may see it, but never lift a hand or offer to prevent it. Consider a tipple boss or shopman working beside a car of cement loaded to go to the mine, and making no attempt to cover or move it in case of an unexpected rain. One pumper tramps all day over a coil of packing, because the other man left it there. A few shovelfuls of dirt, moved in two minutes, may save thousands of gallons of water running into a mine, only to be pumped out again.

A workman can and often does lose a half-hour's time looking for the boss, to tell him a drain is overflowing, when he could have prevented it in 10 min. But, of course, there are things that belong to the other man, and it is not our business to interfere ..ll we are told. Such is usually the case where the system of *kicking the next man* is in use; but coöperation on the part of bosses and men will tend to prevent it. We are each a part of the system that transforms coal into the money of which we all have our share; just as truly as the cogs of a wheel each help to transmit the power from the engine to the load. Remember that the cogs must work together to move the load, and not pound on the ends. So do not pound at either end, in the office or in the mine; but all push together and coöperate to prevent loss and waste. Teach the man next to you, and pass it on to the man with the pick. It will promote loyalty and give better results.

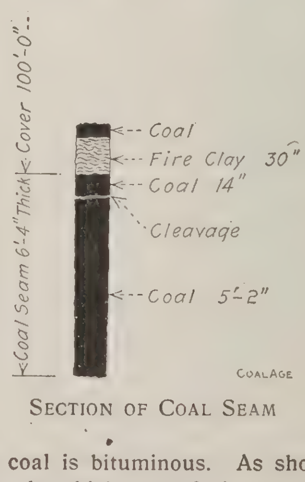
Some well-educated mining men lack ability to organize and coöperate with the men they depend on for their own success. We are glad to see *some* of our superiors come, because we feel they have helped us and they inspire us. We feel more confident, and our troubles are not as large as they looked before when they come. But the other kind of mine official leaves us with a discouraged and depressed mind; our duty seems harder and the load heavier. We wonder why our high-salaried friend does not approve of our work, or show us a better way, and as he disappears we feel the break in the intellectual machinery that is depended upon to get results. We are reminded to "cut costs and put out more coal," and this reminder comes by letter.

MINE FOREMAN.

Uniontown, Penn.

Method of Working a Coal Seam

I would be glad to see in COAL AGE the expression of the opinions of readers as to the best method of working a mine under the following conditions:



SECTION OF COAL SEAM

The coal is bituminous. As shown in Fig. 1, the thickness of the seam is 6 ft. 4 in.; and there is a distinct cleavage in the coal, 14 in. below the roof line. Above the coal is 30 in. of fireclay, and a thin stratum of coal overlies the clay.

The general custom has been to drive the entries 9 ft. wide. The fireclay above the coal weathers and falls when exposed to the air; and the 14 in. of coal next to the roof does not stay up very well. Assuming that the clay cannot be used for making clay products, what is the best way to support the entries and how should this coal be mined? The coal is strong enough so that steel I-beams could be used without legs, if desired, to support the roof.

CHARTER SUBSCRIBER.

Lexington, Ky.

Another Cost Sheet

I note in your issue of Jan. 13, an article by John A. Garcia, on cost sheets and daily reports.

There is one important omission in these forms, and I desire to bring it to your attention. I attach the blank, used by the Consolidated Indiana Coal Co. Items (B) and (C) in the third column of that blank originated in our office. To the information regarding the total cost at the end of each day is added a statement regarding the expenses incurred on previous days of the same month.

The form published by Mr. Garcia is incomplete, because it shows only the expenses on the date which it bears. On idle days and Sundays, more or less expense is incurred, and on our blank this is carried forward, so that the foreman can ascertain not merely the ratio of cost to tonnage on a single day, but the true ratio which he is obtaining over the larger period of time. Under the item which I have marked (*A*), we show the expenses on the date under consideration; under (*B*) the expenses incurred during the portion of the month previous to the date of the sheet, and under (*C*) the expenses on all coal to date, omitting coal used under the boilers.

By requiring each foreman to study these sheets every day, we give him the advantage of immediate touch with his work. This constant reminder has considerable advantage over the delayed report, which Mr. Garcia exhibits in Fig. 2. You will note that earnings and profits are treated on a like basis in the lower right-hand corner.

CARL SCHOLZ,
General Manager,
Consolidated Indiana Coal Co.

Chicago, Ill.

CONSOLIDATED INDIANA COAL COMPANY

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

To Prevent Accumulation of Ice in Shaft

What is the surest and most practical means of keeping a very wet shaft clear of ice in winter? Is there any reasonable method of warming the air before it enters the shaft, or in any other way preventing the shaft from freezing in cold weather? Some have advised reversing the air current every 12 hr., but any one familiar with the conditions knows that it takes the return-air current a much longer time to thaw a body of ice than is required for that ice to form when the mercury is low; and, instead of keeping the downcast shaft clear, this method only tends to render both the downcast and upcast shafts dangerous from the accumulation of ice. Cannot some of the readers of COAL AGE suggest a plan that will be at once feasible and practicable; and that will rid the mines of this annoyance and danger.

THOMAS H. DEVLIN, SUPT.,
Assumption Coal and Mining Co.
Assumption, Ill.

No practical method has ever been devised, to our knowledge, of warming a cold air current before it enters the downcast shaft. To prevent the formation of ice in wet hoisting shafts, in winter, the best plan where this can be done with safety is to make the hoisting shaft the upcast. This plan, however, involves either making the main haulage roads the return airways for the mine, or the use of double doors on the main roads, at the shaft bottom. In a gassy mine, it will generally be unsafe to haul coal on the main-return airways; and it is never practicable to obstruct the main roads with doors.

Owing to these conditions it is generally impossible to prevent the formation of ice in a wet hoisting shaft, in winter, in a gassy mine where haulage is performed on the intake. As stated by correspondent, the alternate, daily, reversing of the air current is not practical, in most cases; and besides causes annoyance and is often impossible to arrange without making special provision for same at the shaft bottom.

The only seeming remedies, in a gassy mine, to avoid the danger of large accumulations of ice, in wet downcast shafts, in winter, is to install suitable water rings, at different levels in the shaft, which will collect the water and render the shaft much drier; or to install at certain levels a system of pipes to be heated by exhaust or live steam, and which could be utilized as occasion would demand. The practise of exhausting steam into the shaft would hardly be applicable to a downcast hoisting shaft owing both to its annoyance and inefficiency. A wet shaft should always be made of ample dimensions to avoid serious troubles, later, in the operation of the mine.

Difference between Carbon Dioxide and Carbon Monoxide

Why is it that carbon dioxide (CO_2), which contains two atoms of oxygen, will not support combustion, but extinguishes the flame of a lamp; while carbon monoxide (CO), which contains only one atom of oxygen, not only permits lamps to burn, but is itself explosive, having the widest explosive range of any of the common mine gases?

Dayton, Tenn. TWO SUBSCRIBERS.

Carbon dioxide is the product of the complete combustion of carbon in oxygen (air), which means that the process of oxidation has reached the limit. The carbon, in other words, has taken up all the oxygen it is capable of absorbing; and the resulting product is fully satisfied or complete. The oxygen thus absorbed is not available for oxidizing any other substance; it is not free, but is tied up in a fully saturated compound (CO_2).

On the other hand, carbon monoxide (CO) is the product of the incomplete combustion of carbon in oxygen (air). In this case, the process of oxidation has not reached the limit; the carbon has a capacity to absorb more oxygen, and would have done so had the supply not been limited.

The difference between these two gases, in respect to their effect on the flame of a lamp, is not that one contains available oxygen that would support flame and the other does not. Neither of them contains any available oxygen. One of these gases, however (carbon monoxide, CO), is not a saturated compound, while the other (carbon dioxide, CO_2) is fully saturated. The former, therefore, is combustible and the latter incombustible.

When carbon monoxide is present in the atmosphere surrounding a lamp flame its combustion, in contact with the flame, adds to and assists the combustion of the flame. The flame burns more brightly than in pure air, owing to the heat developed by the combustion of the gas in the air that feeds the flame.

On the other hand, if the feed air is diluted with an incombustible gas, as carbon dioxide, the effect is to absorb the heat of combustion in the flame, and reduce the temperature and dim or extinguish the flame. Precisely the same effect, in less degree, would be produced if the feed air were to be diluted with nitrogen. The extinctive effect of carbon dioxide is much greater than that of nitrogen, however, because its power to absorb heat is 90 times the heat-absorbing power of nitrogen.

Weight Falling in Shaft

Would there be any difference in the velocity attained by two weights of 1 ton and 1 lb., respectively, falling down a shaft 200 ft. deep? Assuming each weight falls clear, which will strike the bottom first?

Dubois, Penn. INQUIRER.

If it were possible for these two weights to fall in a perfect vacuum, their velocities would be equal, at any instant, throughout the fall; and they would strike the bottom at the same time. This is true, because there is no resistance to retard the falling bodies; and the force of gravity acts equally on each particle of their mass. In other words, under these conditions, there being no resistance, each particle is equally attracted and falls with equal velocity. In a vacuum, a feather falls with practically the same velocity as a lead ball.

Falling in a shaft, however, the resistance of the air, which is approximately in proportion to the surface of the falling body, increases less rapidly than the mass of the body or the attracting force that pulls it down. On this account, the greater weight meets with relatively less resistance in its fall in air, than the less weight. Its velocity, for the same instant, will be greater and it will reach the bottom of the shaft sooner than the lesser weight.

The question is often asked, "Does a man weigh any less when standing in a rapidly descending elevator or cage; or does he weigh any more when the cage in which he is standing is being hoisted rapidly, than when the same man is standing on the ground?" Since *weight* is the product of *mass* and *gravity,* and neither of them change, the man will weigh the same whether rising or falling; but when the velocity of the moving cage is being changed, increased or decreased, the pressure of the man on the floor is changed accordingly.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Questions for Beginners

Ventilating Pressure

Ques.—(a) What is meant by *ventilating pressure,* in mine ventilation? (b) What is the *unit of ventilating pressure?*

Ans.—(c) Ventilating pressure is the pressure producing the circulation, or the difference between the intake and return pressures in a mine, exerted over the entire sectional area of the airway. It is this total pressure in the airway (pa) that pushes or moves the air against the resistance of the mine.

(b) The unit of ventilating pressure or *unit pressure* is the pressure exerted on a single square foot of the sectional area of the airway. It is this unit pressure, or pressure per square foot, in a mine or airway, that is measured by the water gage. Each inch of water gage corresponds to a ventilating pressure of 5.2 lb. per sq.ft. in the airway, at the point where the reading is taken.

Ques.—Show how each inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft.

Ans.—Weight always causes an equal pressure on the base of support. For example, the weight of 1 cu.ft. of pure water (Fig. 1) is practically 62.5 lb. and this causes a pressure of 62.5 lb. per sq.ft. for each 12 in. depth of water. If the water is only 1 in. deep, the weight is $\frac{62.5}{12} = 5.2$ lb., which causes, therefore, a pressure of 5.2 lb. per sq.ft.

An important principle to be remembered is that water always rises to its own level no matter what may be the shape or size of the containing vessel. If the water gage shown on the left of the box, in Fig. 1, were attached to the bottom of the box the inch of depth of water in the box would simply balance the 1 in. of water shown in the gage. This shows clearly that a pressure of 5.2 lb. per sq.ft. is required to balance or produce 1 in. of water gage. The depression of the water in the left arm of the gage represents this pressure.

Ques.—What is meant by the expressions *atmospheric pressure, barometric pressure,* sea-level pressure? Explain briefly the cause of each pressure and how it is different in different places and at different times. What is meant by normal pressure in speaking of the atmosphere?

Ans.—Atmospheric pressure is the pressure due to the weight of the atmosphere pressing on each square unit

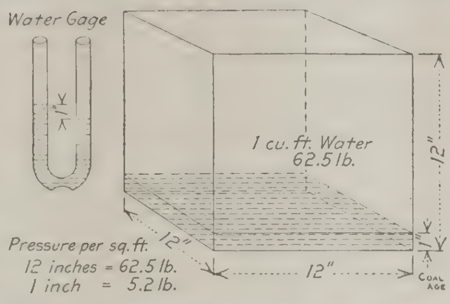

Fig. 1. Showing Pressure Per Square Foot Due to 1 Inch of Water Gage

of the surface of the earth. This pressure is commonly given in *pounds per square inch* or per square foot.

Barometric pressure refers to the pressure of the atmosphere expressed in *inches of mercury.* The weight of a cubic inch of mercury (standard 32° F.) is a trifle less than ½ lb. Roughly, 30 in. of mercury weigh 15 lb.

Elevation above Sea Level (Feet)	Mean Observed Temperature (Fahrenheit)	Weight of Air (lb. per cu.ft.)	Atmospheric Pressure: Lb. per sq.ft.	Lb. per sq.in.	Water Column Maximum Density (Feet)	Mercury Column (Inches)
25,000	0°	0.0327	802.2	5.571	12.85	11.343
20,000	8°	0.0393	981.2	6.814	15.70	13.874
15,000	17°	0.0472	1198.5	8.323	19.17	16.948
10,000	27°	0.0561	1455.4	10.107	23.30	20.582
5,000	41°	0.0659	1760.3	12.224	28.20	24.890
1,000	55°	0.0744	2041.1	14.174	32.70	28.861
Sea Level	60°	0.0764	2116.2	14.696	33.90	29.925

Air Column—1 Ft. Square

COAL AGE

Fig. 2. Showing Effect of Elevation on Temperature and Density of Air, Atmospheric Pressure and Height of Water and Mercury Columns Supported by Atmosphere

Sea-level pressure refers to the common or ordinary (normal) pressure of the atmosphere at sea level, which is roughly 15 lb. per sq.in., or 30 in. barometer.

All atmospheric pressure is due to the weight of the air column above the place where the pressure is measured. This pressure, therefore, decreases as we ascend above sea level, and increases as one descends below sea level, as is true in many deep mines.

Atmospheric pressure changes slightly during each day, being greatest about 10 a.m. and p.m. and least about 4 a.m. and p.m.; there is also a slight change according to the season of the year, being greater in winter and less in summer, in the northern hemisphere. The greatest fluctuation, however, is due to local storms, the storm center being an area of low barometric pressure.

The normal pressure is an average for any place, for the year. It is what the pressure should be under normal atmospheric conditions. Fig. 2 shows an imaginary air column one foot square in section. Starting from sea level, different elevations are marked on the left of the column; and, on the right, the corresponding mean observed temperatures, weight per cubic foot or density of air, the pressure per square foot and per square inch, and the water column and mercury column such pressure will support against a vacuum.

Ques.—What is meant by *absolute pressure?*

Ans.—Absolute pressure is the pressure above a vacuum.

Ques.—Explain the difference between ventilating pressure and absolute pressure.

Ans.—Ventilating pressure is the excess of the intake pressure over the return pressure, for the entire mine or any section of the mine. Absolute pressure is the total or actual pressure borne by the air or gas. When a mine is ventilated on the blowing system the absolute pressure on the air in the fan drift is equal to the atmospheric pressure *plus* the mine ventilating pressure. In case the fan is exhausting instead of blowing, the absolute pressure on the air in the fan drift is equal to the atmospheric pressure *minus* the mine ventilating pressure. In each case, it is necessary to reduce the mine pressure to lb. per sq.in., or else estimate the atmospheric pressure in lb. per sq.ft.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The employers' liability and workmen's compensation commission has made public the text of a bill representing the results of its deliberations during the past year. The bill applies chiefly to railroads, but it is intended subsequently to extend the provisions further and to attempt to make them a basis for uniform state legislation; that is, if the measure is adopted, as it probably will be. The proposed bill is therefore of general industrial significance. As offered by the commission it provides that:

"Every carrier engaged in interstate or foreign commerce by railroad shall pay compensation in the amounts specified in the bill to any of its employees who, while employed by such employer in such commerce, sustains personal injury by accident arising out of and in the course of his employment and resulting in his disability, or to his dependents in case of death.

"That the remedy thus afforded shall be exclusive, and that all existing common-law and statutory remedies, so far as future cases are concerned, shall be abolished." And that:

"This compensation is to be paid in every case specified irrespective of negligence, except where the injury or death is occasioned by the willful intention of the employee to bring about the injury or death of himself or another or when the same resulted from his intoxication while on duty."

Fixed schedules of compensation for death and personal injury are submitted, together with numerous rules, conditions and provisions for various contingencies.

Cost of Carrying Coal to Panama

Extensive inquiries into the cost of carrying coal to the Panama Canal by government vessels have been undertaken by Secretary Meyer and the results thereof supplied to the House Committee on Interstate and Foreign Commerce, in order that members may be able to judge of the relative cost of supplying coal at the canal by government agency and by private enterprise. The statements which are now before the committee show that in the case of the "Cyclops," one of the newest and best of the government colliers, the combined cargo and bunker capacity is 12,500 tons, maximum speed 14 knots, economical speed about 10 knots and cost $822,500.

Based on the cost of operating the "Cyclops," the annual operating expenses of the proposed canal colliers would be approximately $196,000 and allowing 15 round trips annually, the delivery cost per ton of coal would be about $1.14.

There is little doubt that these proposed colliers could deliver coal at Colon more cheaply than could private merchant ships. In comparison with the estimated cost of $1.14 per ton, the following freight rates by steamer to points in the West Indies and Caribbean during 1911 are compiled from the W. W. Beattie & Co.'s Coal Trade Freight Reports:

From Norfolk to	Low	High	Average
Havana, Cuba	$1.30	$1.85	$1.57
Matanzas, Cuba	1.30	1.85	1.57
Cardenas, Cuba	1.50	2.25	1.87
Cienfuegos, Cuba	1.50	2.25	1.87
Port of Spain, Trinidad	1.75	2.50	2.10
St. Lucia	1.65	2.30	1.97
St. Thomas	1.40	1.90	1.65
Barbados	1.75	2.50	2.12
Kingston	1.40	1.90	1.65
Curacao	1.15	1.70	1.42
Vera Cruz	1.60	2.25	1.92
Guantanamo	1.50	2.20	1.85

Assuming that the canal will require 3000 tons of coal per day at first, the gain from employing government colliers would be $788,400 annually, and when the business of the canal shall have increased to equal that of the Suez Canal the annual gain would amount to about $2,102,400. This estimate is based on an initial canal traffic of five ships per day, each ship taking 500 tons of coal, and ultimately a traffic of 15 ships per day. It is assumed also that the canal power and lighting plants, the Panama R.R., etc., will use at least 500 tons per day.

Charges for Dumping and Trimming

The Interstate Commerce Commission has rendered an important decision in the case of the New England Coal & Coke Co. vs. the Norfolk & Western Ry. Co. *et al*, in which it holds that:

1. Trimming, or leveling coal in the holds of ships, is a necessary service in connection with the transportation of coal by water, and, where performed by the rail carriers, it must be regarded as a part of the delivery. Whether or not defendants legally might be compelled to render such service, when they undertake so to do any charge therefor is subject to regulation by this Commission.

2. The charges of 3c. per ton for trimming and 4.5c. per ton for dumping and trimming are not found to have been unreasonable. The charge of the Virginian Ry. of 4.5c. per ton for trimming alone is found to have been unreasonable to the extent it exceeded 3c. per ton. Reparation is awarded.

Alabama

Birmingham—It is understood that the differences between the state and the Sloss-Sheffield Steel & Iron Co., regarding the agreement for mining coal with state convicts, have been satisfactorily adjusted by a few slight amendments to the contract. One of the provisions of the contract was the expenditure of about $10,000 in improvements of various kinds at the mines. These improvements are well under way. They have to do with enlargements of barracks and the installation of a more extensive sanitary system.

Colorado

Denver—The government has brought suit to recover the patent to 160 acres of coal land in Huerfano County and $100,000, said to be the product of the land. The Beacon coal mine is located on this property, which has passed through the hands of a half dozen owners since original entry was made six years ago. The government maintains that the land was obtained by fraudulent entry.

Representatives of the Denver Trades and Labor Assembly, the Direct Legislation League and other bodies interested in having the state operate and control coal mines, have agreed upon the form of the bill to be presented to the people for their approval at the next election for members of the general assembly. It provides that all land, bearing coal which is now owned by the state or may later be acquired, shall never be sold. An administrative board is provided for and is empowered to engage in the business of mining coal and selling it to the consumer.

Illinois

Chicago—A sweeping investigation of conditions governing the distribution of coal cars at mines in Illinois, Indiana, Kentucky, and Ohio will be made by the Illinois State Railroad and Warehouse Commission during the next few weeks with a view to establishing some uniform rule covering such distribution in this section of the United States. The Inter-

state Commerce Commission and the different railroad commissions of the states mentioned will be invited to participate in the investigation and subsequent hearing, at which it is proposed to establish a uniform rule.

The Illinois Central R.R. Co. has apparently overcome the dissatisfaction in several of the mining towns on its line that was caused by the failure of the railroad to furnish cars enough to enable the mines to work more than one day per week. Every coal-mining town on the road has now received orders for company coal, which is being stored in the open fields around the mine tipples.

Litchfield—A deal was consummated recently by Chicago and New York capitalists that consolidates four of the leading coal mines in Montgomery County and places them under the control of one company. The four mines involved are: Taylor Springs, Kortkamp and the two Witt mines. It is probable that the new company will take over the mines at Nokomis, also in this county.

Murphysboro—Fire, Feb. 18, destroyed the plant of the Knickerbocker Briquet Co., one mile from Murphysboro, and adjacent to the Harrison mine, of the Big Muddy Coal & Iron Co. The loss was $100,000. The plant was erected three years ago, being the only one of its kind in the high-grade coal field of southern Illinois, and is owned by A. G. Kupfel, of New York.

Witt—Burnwell mine No. 2 was closed down for several days recently by an accident to a hoisting cage. The bridle chains broke and the cage fell from a point within 20 ft. of the top of the shaft to the bottom, a distance of about 500 ft. Coal was being hoisted at the time.

Indiana

Princeton—Drilling operations are being carried on in this vicinity by the Princeton Coal Co. to determine the value of the No. 4 seam, which lies 50 ft. below the surface. If the seam proves to be as expected a new mine is looked for in the near future.

Vincennes—It was announced recently that the Martin-Howe Coal & Mining Co., of Chicago, will enter the new coal field that is under development near Bruceville. The Martin-Howe company is interested in the Freeman and Tecumseh mines at Bicknell. The property this company intends to develop is two miles southeast of Bruceville.

Iowa

Des Moines—Union miners of Iowa will meet in annual convention here on Mar. 14. They will come prepared to demand a raise in wages of 10c. a ton and of 20 per cent. for day work. The operators will refuse to meet that demand, and as a result it is predicted that the mines of Iowa will all shut down on Apr. 1 until a new wage scale is agreed upon. Railroads and other large consumers of coal in the state are already preparing for the shutdown by storing large quantities of coal as rapidly as possible. Representatives of the miners and operators will meet in wage-scale conference on Mar. 21, one week after the opening of the miners' convention.

Kansas

Columbus—Owners of business buildings in Weir City have applied to the district court for an order to restrain R. L. Thorp from mining coal under the streets and certain lots of the city. The applicants allege that if the mining operations are continued there is reason to fear that buildings will be jeopardized. While extensive mining operations have been carried on within the municipal limits since the field was developed, this is the first time the city has attempted to stop them or to collect the value of coal removed.

Pittsburg—The coal fields in Kansas, Missouri, Oklahoma and Arkansas are operated by firms belonging to the Southwestern Coal Operators' Association. The operators and the miners in this field signed a two-year contract, which will expire Mar. 31, but the contract contains a provision that the mines must continue in operation for the period from the expiration of the contract to Apr. 30, while the miners and operators are negotiating a new contract.

Kentucky

Louisville—Local coal operators are interested in the organization of a new coal company which will have a capital stock of $2,000,000, and which will carry on operations on a large scale in the newly opened Harlan County fields. The Kentucky Mutual Coal Corporation will be the title of the new organization, and will be composed of New York and Kentucky capitalists. The proposed company will take over the holdings of a number of smaller concerns in southeastern Kentucky and will conduct coal operations on a large scale. The full details have not been perfected, but it is expected that all plans will materialize within the next few weeks.

Greenville—Coal operators in western Kentucky are complaining of the rating placed on their output by the Illinois Central R.R. Co. This assumed output forms the basis for car distribution by the railroad and greatly reduces the number of cars that are to be furnished the mines in western Kentucky, the number to all mines on this division, with possibly two exceptions, being reduced. The matter of the right of the railroad thus to fix the output of the mines by limiting the supply of cars furnished will be called to the attention of the Kentucky railroad commission, and also to the interstate commerce commission.

Missouri

Huntsville—The coal washer that has been under construction for a number of months at the old No. 10 plant of the Northern Central Coal Co. has recently been completed and tried out with satisfactory results. The washer was built at considerable expense and embodies uptodate methods and modern machinery.

Ohio

Toledo—Over 12,000 cars of coal were found Feb. 18, to be tied up in the blockade at Toledo, owing to the inability of the Michigan lines to handle the cars. The Pere Marquette declared an embargo on coal. The value of the hard and soft coal tied up at Toledo was estimated at about $3,000,000. Every available storage switch and sidetrack between Columbus and Toledo is filled with loaded cars of coal, and it is said that thousands of tons of coal are northward bound from the southern Ohio and West Virginia fields.

Cleveland—Arrangements have been made by a Cleveland coal shipper with a firm which owns a large fleet of boats, to float in the neighborhood of 400,000 tons of coal. The contract does not call for any specific rate, but the freight will be charged at the going rate. This makes more than 650,000 tons of soft coal that have been contracted for recently.

Columbus — Considerable interesting evidence was adduced at the hearing of the interstate commerce commission in Columbus recently in the case of the New Pittsburg Coal Co. which challenged the lake rates from the Hocking Valley. The present rate is 90c. and an effort is being made to have it reduced to 75c. or less.

There is a division of sentiment on the probability of a suspension at the expiration of the present wage scale. Some of the operators and jobbers profess to feel that the miners will agree to work pending a settlement of the scale but others are inclined to believe that such a course is improbable. The miners usually have gone out pending a settlement of the scale and there is nothing at this time to indicate a change in that custom.

Oklahoma

Lehigh—A serious fire started in the No. 5 mine of the Western Coal & Mining Co., near here in the morning of Feb. 22. The workings lie about 300 ft. below the surface and the number of men at work at the time is variously estimated at between one and two hundred. Most of the men escaped through an abandoned shaft about two miles from the main entrance to the mine. Thirty cars of coal

that were standing in the workings are reported to have added materially to the flames. Last advices state that 8 bodies have been removed and one man is still unaccounted for. It is believed that these comprise all the casualties. A score of men were entombed, and later rescued. Rescue parties from the government station at McAlester were rushed to the scene and immediately began exploration of the workings near the mouth of the pit.

Pennsylvania

Bituminous

Butler—The Sharon Coal & Limestone Co. which has been operating in this section for some time, recently secured leases on a number of acres of coal land in Mercer and Slippery Rock townships. The company has expended considerable money testing for coal on these properties. The total amount of land leased so far is 671 acres but it is expected that additional leases will be made in the same neighborhood.

E. W. Eisler, of Butler, who has taken up a number of options on coal land in Middlesex township, recently purchased the H. W. Flick farm in that township, paying $12,000 for its 99 acres. This farm is centrally located in the property held by Mr. Eisler and it is expected that active development of his holdings will commence during the present year.

Somerset—Interests affiliated with the Western Maryland R.R. Co. are understood to be negotiating for the Brothers-Valley Coal Mining Co.'s plant near Berlin. The plant is one of the largest in this section and would give the Western Maryland a big tonnage. Now that the Western Maryland's tracks are going down rapidly, agents are in the field trying to option coal lands, and everybody is waiting for spring to give the signal for considerable activity.

Connellsville—The number of active ovens in this region has been increased by the firing of 50 at Mt. Braddock, 40 at Dexter, 80 at Elizabeth, 25 at Griffin and 10 at La Belle; total, 205; and decreased by the blowing out of 25 at Grace, 10 at Cyrilla, and 12 at Eleanor, total, 47, making a net increase of 158 ovens.

Pittsburg—A large delegation appeared before the rivers and harbors committee of Congress, in Washington, Feb. 19 and advocated the extensive improvement of the Allegheny River in order to facilitate shipping.

A party of more than 40 officials, employees and guests of the Pittsburg branch of the U. S. Bureau of Mines, went to Bruceton, Feb. 24, for the second of a series of explosions at the government's experimental coal mine there, to determine the best means of preventing mine disasters. The tests were in charge of Chief Mining Engineer G. S. Rice.

Anthracite

Scranton—A federal grand jury, at Albany, N. Y., Feb. 21, returned indictments against the Delaware & Hudson Co., charging violation of the commodities clause of the interstate commerce law. There are 30 counts in the indictment, which is the beginning of a campaign by the government to force the railroad to give up the ownership of its coal mines.

The conference between representatives of the anthracite operators and miners, held in New York, Feb. 27, lasted about 15 minutes. The miners' demands were presented and taken under consideration by the operators. A meeting of representatives of the operators will be held, Mar. 5, and a committee appointed to confer with the miners. A joint conference will be held, probably Mar. 13.

The Delaware & Hudson company is building a new breaker at its "Gravity Slope" mine, near Winton, Lackawanna County.

Wilkes-Barre—Coal companies in this section expect, during March, to store at their various collieries a large quantity of steam coal for their own use. They anticipate, if there is no strike following the expiration of the existing agreement, that there will at least be a suspension of work for some weeks, during which time the miners' leaders will conduct negotiations with the operators before finally reporting to the men their decision regarding the situation.

Virginia

Bristol—It is reported that H. K. McHarg, Jr., a wealthy capitalist of Radford, Va., has bought a controlling interest in the Empire Coal Land Corporation, a concern which owns several thousand acres of Wise County, Va., coal lands, a large part of the properties lying along the Kentucky border.

West Virginia

Wheeling—The Herbert Collieries Corporation, which has its principal offices, in New York, and is engaged in mining coal on leased lands in Fayette and Raleigh Counties, West Virginia, filed a voluntary petition in bankruptcy, Feb. 24, giving liabilities of $244,083 and assets of $168,898. The assets, the petition states, include leases of mines in West Virginia valued at $150,000, stock in a mine store at Herberton, W. Va., worth $10,000, and debts due aggregating $6398. The mines operated by the corporation were leased from the McKinley Fuel Co. by Preston B. McClarahan, who assigned his interest in the properties to the Herbert Collieries.

The Western Maryland R.R. is hauling large quantities of coal from West Virginia mines to Baltimore, and Hagerstown, Md. The increase has been so great within the past few weeks that there is great difficulty in getting sufficient engines to move the trains, causing congestion in the various yards of the railroad. It is said, there are 15,000 carloads of coal stored on these lines awaiting transportation.

Wyoming

Sheridan—Increased freight rates proposed by the Chicago, Burlington & Quincy R.R. on coal from mines in Wyoming to junction points in Montana and beyond were suspended, Feb. 17, by the Interstate Commerce Commission, pending an investigation.

It is stated that mines in the southern part of the state are operating more steadily than those in the local field. This fact is accounted for on the grounds that the southern mines are largely owned by the railroad and smelting interests and their entire production is used by these interests, while the northern mines are commercial mines and depend upon the market to handle their product.

Canada

Victoria, B. C.—The British Columbia government proposes to send engineers to the country between Stewart and Ground Hog Mountain to obtain data for the proposed construction of a railroad from Stewart to tap the Ground Hog Mountain coal fields, this line eventually to form a link in another trans-continental system.

The next examination for mine managers, overmen, fire bosses and shot lighters will be held the latter part of April or early in May.

Calgary, B. C.—The city council has placed itself on record as in favor of having the municipality own and operate a coal mine, and has authorized placing $2500 in the estimates to cover the cost of investigating the different propositions offered to the city.

Great Britain

London—A national coal strike was virtually inaugurated, Feb. 27, when between 30,000 and 40,000 miners in Derbyshire and Nottinghamshire ceased work. This number was increased to 100,000, Feb. 28. No settlement was reached at the various conferences, Feb. 27, between the government and representatives of the miners and operators, although it was reported that the outlook had become more hopeful. Large purchases of Pocahontas coal for the British navy are announced. This will be shipped from Norfolk within 60 days. The first shipment of 25,000 tons will go forward as soon as the chartered steamers arrive.

Personals

John W. Braham has resigned his position with the West Virginia Colliery Co., at Wevaco, to become superintendent for the Clear Fork Coal Co., at Jarrolds Valley, W. Va.

J. E. Pettit, Utah state coal mine inspector, has returned to Salt Lake from a trip through Emery County, where he visited the mines at Castle Gate, Mohrland and Price.

E. J. Wallace has severed his connection with the Mississippi Valley Fuel Co., St. Louis, Mo., effective Feb. 19, and is now handling his trade from an office in the Victoria Building.

James Needham, president of the St. Paul Coal Co., is making an extended visit to the mining properties of the company in the West and expects to return to Ottawa, Ill., early in March.

T. K. Adams and Enoch W. Filer, of Mercer, Penn., and George Young, of Stoneboro, have been appointed members of the examining board for the third bituminous district of Pennsylvania.

B. B. Thayer, president of the Anaconda Copper Mining Co., in company with F. W. C. Whyte, general manager of coal properties, recently made an inspection of the company's coal mines at Diamondville, Wyoming.

R. A. Gray, general manager of the J. R. Crowe Coal Co., of Pittsburg, Kan., is taking full charge of the company's business in the absence of Mr. Crowe, who is making an extended trip to Panama and South America.

E. E. Bach has been appointed sociological superintendent, in charge of improvement work at the Ellsworth and Cokeburg plants of the Ellsworth Collieries Co. In creating this office the Ellsworth company has taken a pioneer step, so far as the coal industry is concerned.

Elmer E. Thomas, of Omaha, a representative of the United States Coal Co., together with C. V. Gould, of Chicago, a civil engineer for this company, have been in the vicinity of Kemmerer, Wyo., for some time, arranging for the opening of a new coal mine in this district to be located on the old Adaville property.

George O. Thomas, of Wilkes-Barre, Penn., for 20 years superintendent of the Clear Spring colliery, West Pittston, until its abandonment recently, has been appointed general inside superintendent of the Harleigh and Pond Creek collieries near Hazleton. Mr. Thomas has lately filled the position of inside superintendent of the Parrish and Buttonwood mines of the Parrish Coal Co. at Plymouth. The collieries named, both at Hazleton and Plymouth, are controlled by Madeira, Hill & Co., of Philadelphia.

Obituary

T. Guilford Smith, a member of the firm of Albright & Smith, agents at Buffalo for the Philadelphia & Reading Coal & Iron Co., died at his home on Feb. 21, aged 72 years. He was well known in the coal and iron trades and actively identified with educational work in New York state. Mr. Smith was a member of several American and international scientific organizations.

Construction News

Birmingham, Ala.—The Bryan Coal Corporation, of Birmingham, will make extensive improvements on its property, at Red Star, including the erection of a coal washer. It is estimated that about $225,000, in all, will be expended. Frank Nelson, Jr., is president.

The Cullman Coal & Coke Co. is reported to intend completing the railroad from Cullman to the Bremen coal fields.

Calvert, Tex.—The Central Texas Fuel Co. is preparing to develop about 250 acres of land for an output of 500 tons of coal per day. Machinery will be required at an early date, and an aërial tramway, about ½ mile long, will be constructed. Robert Magee is constructing engineer.

Barbourville, Ky.—The Clover Fork Coal Co., of Harlan, Ky., capitalized at $50,000, will develop 800 acres of coal land for an output of 500 to 1000 tons per day. Machinery and other equipment will be installed. B. W. Whitfield is the engineer in charge.

Scranton, Penn.—Kingsley and Wescott, of this city, have secured the contract for rebuilding the Bernice breaker of the Connell Anthracite Coal Co., which was recently destroyed by fire. Cost to be about $125,000.

Duluth, Minn.—The contract for the machinery equipment of the new Island Creek Coal Co.'s dock has been awarded to Heyl & Patterson, Pittsburg, Penn., at about $300,000. The Zenith Dredge Co. has secured the dredging contract in connection with this work at $100,000.

Bay City, Mich.—The Robert Gage Coal Co. will sink a new shaft near St. Charles this spring. Charles Coryell is manager.

Pittsburg, Penn.—The U. S. Bureau of Mines is planning to enlarge the testing station at Fortieth and Butler Sts. The new buildings will cost in the neighborhood of $200,000. H. W. Wilson is engineer in charge.

Indianapolis—The Rowland Block Coal Co., recently incorporated with a capital of $100,000, will sink shafts, build tipples and install machinery to do a coal- and clay-mining business at their property near Parkersburg, Owen County. George Rowland is a director.

Publications Received

ANNUAL REPORT OF STATE MINE INSPECTOR, SOUTH DAKOTA, FOR 1911. By Robert L. Daugherty. 16 pp., 6x9 in.; pamphlet.

BRITISH COLUMBIA COAL AND COKE. Pamphlet. 14 pp., 4½x7½ in.; illustrated.

This little book is issued for private circulation by W. E. Duncan, M. E., a consulting engineer of Merritt, B. C. It presents interesting news and facts concerning the British Columbia field and includes a directory of the companies operating in this region.

EXPLOSIVE MINE GASES AND DUSTS. By Rollin T. Chamberlain. Bulletin No. 26, U. S. Bureau of Mines. 67 pp., 6x9 in.

This report is a reprint of U. S. Geological Survey Bulletin No. 383, and has special reference to the explosions in the Monogah, Darr and Naomi coal mines in December, 1907. The results of the experiments set forth in this bulletin and the conclusions drawn have become generally familiar to the mining industry since their first publication in 1909.

Industrial Notes

The J. A. Brennan Drilling Co., of Scranton and Pittsburg, Penn., announce that during the year 1911 they took out over 30,000 ft. of cores in connection with diamond-drill operations on prospecting work. This company is fully equipped to undertake drilling work in any part of the United States, Canada, Mexico, or South America and contracts to produce a continuous core showing the strata beneath the land under examination.

The Best Manufacturing Co., Pittsburg, Penn., announces that it has engaged the services of Howard W. Evans as general manager of sales, who will hereafter supervise the sales, order and engineering departments. Mr. Evans is a specialist in this line of work and will be pleased to advise with prospective buyers of piping materials. With its new plant and complete engineering force, the Best company states that it is in a position to lay out entire piping systems, furnishing the material, cut and fitted ready for erection or to take contracts to furnish and install such systems complete and ready for operation.

E. B. Day, secretary and treasurer of the West Virginia Mining Institute, 108 Smithfield St., Pittsburg, Penn., is placing on the market a map-directory covering the State of West Virginia and two counties of Maryland. It is printed on linen, of a size suitable for hanging on the wall and gives among other matters, the location and authentic information concerning 500 mining companies and 815 mines in the territory covered. Each mine is numbered on the map and is thus referred to a chart directory giving the name of the operating company, the names of the various officials with the addresses of each, the name of the mine with its post office address, county, and railroad connections, the seam mined, thickness, kind of opening, kind of haulage, method of mining, number of men employed, number of coke ovens, capacity of mine, grades shipped, trade name and analysis of coal.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

With the prospective strike of the union miners now less than a month off, and only sufficient fuel in sight to meet current demands, the coal industry probably never faced a labor crisis under less favorable conditions. Strike possibilities in the past have invariably been anticipated by operators and consumers alike by the accumulation of large storage reserves, while in this instance supplies generally are reported low, and in many cases below all previous records. In view of the fact that for the first time both the anthracite and bituminous agreements expire simultaneously, this shortage in supplies is of particular significance.

The movement on railroads has improved materially during the past week, with the exception of some isolated districts, which are still feeling the effects of the congestion. Many large consumers will doubtless avail themselves of this opportunity to acquire what surplus stocks they can between now and Apr. 1. As is well known, the capacity of the mines—except in anthracite—far exceeds that of the normal consumption, and with favorable transportation conditions in effect, there is still an opportunity for the storage of heavy tonnages. That the operators of the Middle West are thoroughly alarmed over the outlook is evidenced by the fact that the entire output of some mines on the Illinois Central (on which the car service is particularly bad) is being stored on the ground.

On the other hand, many large steam users are not manifesting a very strong desire to stock because of the ruling high prices, due to the scarcity in all grades and sizes. They are withholding their requisitions pending a return to more normal conditions in the trade, and a consistent adherence to this policy will tend to make the situation still more acute, later. In any event, the trade will technically require a strike of short duration or suffer a severe depression during the period the surplus supplies, now being accumulated, are worked off.

Boston, Mass.

The expected has happened and prices are decidedly on the upward trend. At all points bituminous has jumped to high figures, and something of a scramble prevails at distributing centers. With contracts expiring Mar. 31, buyers are striving to cover supplies at least to May 1, and apparently figures will be reached that have not been quoted since 1903. Available coal is snapped up as soon as it is offered, and from a selling standpoint, each sale turns out to be a poor one. At the same time one large distributing company at Boston is naming \$3.80 on cars, Mystic Wharf, for yearly contract, as against \$3.30 for similar trade a year ago.

Pennsylvania bituminous has a ready call at tide, both at New York and Philadelphia, and at prices considerably advanced. The higher grades along with Georges Creek are out of the question for new purchases.

Marine freights are also firmer, \$1.25 having been paid Hampton Roads to Providence on a large tonnage, and \$1.35 to Boston. As high as \$1.25 is freely paid New York to Boston on anthracite, and \$1.15 to Providence for the same loading.

Anthracite is far behind on deliveries, and no hopes are held out; it has gone beyond a matter of sizes. From New York almost nothing is being received except individual coals in transportation engaged in the open market. What company barges arrive are loaded with screenings and stock egg. Broken and pea are not to be had. The situation is critical and there are interesting times ahead.

Prices range about as follows:

Clearfield[1]	\$1.55@1.75
Somerset[1]	1.70@1.85
Bituminous, en route to junction points[1]	1.90@2.20
Pocahontas, New River[2]	3.25@3.35
No. 4 Pocahontas, Clinch Valley, etc.[2]	2.75@3.00
Pocahontas, New River, Boston or Portland, on cars	5.00@5.25
Pocahontas, New River, Providence, on cars	4.75@5.00
Anthracite, egg and stove[1]	4.25@4.50
Anthracite, egg and stove, f.o.b. New York	5.25@5.50

[1]For shipment f.o.b. mines.
[2]F.o.b. Hampton Roads.

New York

Strike talk, combined with the short supply of soft coal here, has greatly stimulated the New York market and prices have advanced rapidly until even the lowest grades of steam coals are being held at from \$2.90 to \$3, f.o.b., and only a very small tonnage can be bought at those prices. The supply at the piers is extremely limited and shippers are barely able to take care of contract requirements with the coal they have available. The market here has not been so short in a long time.

All-rail demand is strong and prices for line shipment have also advanced. About the only coals that can be obtained for prompt shipment are of very ordinary quality and these readily command from \$1.35 to \$1.50, f.o.b. mines.

From consumers located on shoal-water points, shippers are beginning to receive orders to commence deliveries as soon as navigation opens. This would indicate that the supplies, accumulated last year, to carry over the winter period, have been reduced excessively by the severe winter, as ordinarily their stocks carry them well into April.

Philadelphia, Penn.

There is practically no change in the retail trade in this locality. The dealers all continue busy—not with the feverish activity of some few weeks ago, but there is a good demand, which depletes their stocks as fast as they can be accumulated. Pea coal seems to be the most difficult to procure at the present time, and as high as \$2.50 at the mines has been paid, with little of this size offering at that.

Pea size, since the advance in the price of chestnut, has been experimented with by quite a number of householders, and, in some cases, has been found to answer the purpose fairly well. A number of the furnaces in this city are equipped with grates to burn this particular size of coal, and the added number of users has made it a scarce article.

Stove and chestnut, in fact, all sizes, are in splendid demand, and the dealers all report substantial increases over the same period a year ago, when business in this line commenced to grow rather sluggish. The weather for the past week, while not cold, still compels the use of considerable coal.

The wholesale trade still enjoys a full measure of prosperity. Every pound of coal at the present time is going direct to the consumer, and, as an index of conditions, orders for certain sizes are either turned down or taken with the proviso that shipments will be made as promptly as possible, which is practically no promise at all.

Pittsburg

Bituminous—There has been some discussion of the proposition in certain districts that the miners work for 45 days after the expiration of the old wage scale, pending the fixing of a new scale, but

there is not the least likelihood of the necessary unanimity being reached, and it remains probable that there will be a general suspension in the union districts for perhaps 60 days. Nothing has been accomplished toward bridging the difference between the respective demands of the operators and miners.

The local coal market continues strong, with nearly all mines working to as large outputs as the car supply permits, which means about 85 per cent. of capacity in the district as a whole. Prices are firm at the advanced level noted a week ago and may soon score a further advance. We quote: Nut, \$1.10@1.20; mine-run, \$1.15@1.25; ¾-in., \$1.25@1.35; 1¼-in., \$1.40@1.50; slack, 90c.@\$1 per ton at mine, Pittsburg district.

Connellsville Coke—Prompt furnace coke continues scarce and is bringing practically as high prices as ever. There is practically no demand for furnace coke on contract, the furnaces now in operation being already well covered. Some of the brokers have not been able to catch up in deliveries on contract, and a considerable part of the demand for spot coke comes from them. We note sales of between 50 and 75 cars of prompt furnace coke in the past week, chiefly at \$1.80 and \$1.85, and quote the market unchanged as follows: Prompt furnace, \$1.80@1.90; contract furnace, \$1.80@1.90; prompt foundry, \$2.20@2.30; contract foundry, \$2.20@2.40 per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Feb. 17, at 393,364 tons, an increase of 39,000 tons, and shipments at 4582 cars to Pittsburg, 6416 cars to points West, and 864 cars to points East, a total of 11,862 cars, an increase of 1300.

Baltimore, Md.

The demand for practically all grades in this market has been exceptionally good, and prices, for the most part, remained firm. The trade is still facing unfavorable car movements on all the railroads; while some of the local operators were able to deliver with less difficulty through the week than heretofore, the majority of the offices reported that they encountered serious delays during the week, and that the car shortage was as bad as when the thermometer was registering around zero.

The prevailing opinion in Baltimore is that a strike in both the bituminous and anthracite fields will take place, and large orders were received during the past week for stocking-up purposes. These consumers, it is stated, will remain in the market until it has been definitely determined just what will be the outcome of the negotiations between the miners and operators.

Buffalo, N. Y.

The coal trade is in an uncertain condition, and promises to remain so for some time. Just now the weather is the chief element; when the thaw of mid-February came on, the consumers, both of anthracite and bituminous, took it for granted there would be no more severe weather and began canceling their orders. When the big blizzard of Feb. 21 appeared, everybody was dumbfounded, both at its severity and its effect on the railroads. It is now said that it will be April, at least, before the roads are in condition to deliver nonperishable freight to all points promptly.

There is some coal getting to destination from the sidings Eastward and prices are actually firmer in Buffalo than they are in the East. Shippers are astonished to find how little the general consumer has become awake to the situation, and the state of distress into which the roads and shippers have been for weeks finds little sympathy at the other end of the line.

It is difficult to quote bituminous, as there is no settled price; the shipper feels that he is entitled to an advance and he is earning it, but the consumer still finds coal at former prices. Quotations must, therefore, remain strong at former figures: \$2.60 for Pittsburg three-quarter; \$2.50 for mine-run and \$2.25 for slack, with Allegheny Valley coal about 25c. less. Coke is fairly strong at \$4.25 for best Connellsville foundry, and \$3.50 for stock.

The anthracite trade is a trifle more hopeful; the demand is not so insistent as it was and it will run down still more as soon as mild weather returns. Shippers have no surplus and do not expect any right away. The Western situation is reported a little easier, especially as the last cold spell did not strike that section as severely as it did the East.

Cleveland, Ohio

Conditions in the past week have been rather serious on account of car shortage, and while there has not been any actual suffering on account of the scarcity, nevertheless there has been quite an uneasiness because of the small amount moved from the mines. The railroads have been unable to deliver the heavy tonnages moving into the West and North during the past six weeks because of the snow blockade; as a result of the large number of loaded cars laid out on sidings the roads are short of equipment and cannot furnish empties to the mines. We are assured, however, by the railroads that now that the severe weather has abated the empties will be returned promptly and the mines will be supplied next week.

Prices have advanced on all grades of coal in the past week from 15 to 25c. per ton in this market. It is not expected, however, that these prices will remain after an adequate car supply has been furnished.

Columbus, Ohio

Just at the time when railroads were beginning to relieve the congestion of traffic incidental to the extreme cold weather of the months of January and February, another storm appeared and again demoralized traffic on all of the roads. As a consequence the condition is even worse than it has been at any previous time during the winter, and there is little hope for an immediate remedy unless more favorable weather appears.

Prices are still ruling firm, and there is a premium on all grades and varieties. Many manufacturing establishments had to close down temporarily to permit of the coal supply being used for heating purposes. Some suffering was reported in certain localities, but this was not widespread nor severe.

Operations in Ohio mining districts have been restricted to about 50 to 60 per cent. of the average. The chief hindrance has been the inability to secure sufficient cars. Motive power is lacking on the railroads and the general condition of traffic is demoralized to the extreme.

Retail trade has been active because of the low temperatures which have been prevailing. Consumers were compelled to place additional orders, and the ice on the streets made deliveries rather difficult. Prices in retail circles rule firm and higher.

Prices prevailing in Ohio are as follows:

Hocking Valley	
Domestic lump	\$1.60
¾-in.	1.40
Mine-run	1.15
Nut	1.15
Nut, pea and slack	0.80
Coarse slack	0.70
Pittsburgh No. 8	
¾-in.	1.30
Mine run	1.10
Coarse slack	0.80
Pomeroy Bend	
Domestic lump	1.75
¾-in.	1.50
Mine-run	1.20
Kanawha	
Domestic lump	1.40
¾-in.	1.25
Mine-run	1.05

Cincinnati, Ohio

Conditions are little changed from what they were a week or ten days ago. There has probably been a lessening of the pressure on traffic officials, owing to the gradual clearing up of congestion at the various terminal points on most railroads in this territory. For this reason also, the wholesale offices feel the tendency is in the right direction, so far as pressure on them is concerned for delivery of orders long overdue. They have in no way been responsible for the delay, although the buyer is inclined to consider them so.

The demand for the various grades of fuel is practically unchanged, either relatively or as a total. Fine coals are strongest, with some grades nearly impossible to get. As soon as the railroads are on something like a normal basis again, as regards deliveries, it is probable there will be a big drop in the orders in wholesale offices. Many orders now on hand are doubtless duplicated in more than one office by the purchaser. When he has enough in his bins, regardless of whom purchased, he will stop shipments by canceling other orders, which he can readily do on the ground that delivery was too long delayed, and the delays have been such within the last 60 days that no seller could deny them.

Thurmond, W. Va.

The cold snap of January, which was hailed as a sure promise of better prices and increased output, has caused the worst congestion of movement on the western railroads connecting with the Chesapeake & Ohio and the Norfolk & Western that they have ever seen, while at the same time the demands for coal have been largely increased, both on contracts and for spot shipments. Owing to the large number of cars tied up, more particularly in the Toledo district, where there are about 14,000 loads, the supply of empty cars is so small that the mines here are working only about two and one-half days per week. Some of the Middle West railroads are stocking up, in anticipation of a strike, the Pennsylvania Lines having placed orders for 60 cars daily, and this is tending to add further complications.

A price of $1.25 per net ton, f.o.b. mines, is being quoted on all spot coal, and sales at $2.85 per gross ton, f.o.b. Hampton Roads, have been made.

The Chesapeake & Ohio and Norfolk & Western are moving such coal as is loaded to tidewater in good time and returning empties quickly, but the Virginian Ry. has fallen down completely, owing to a strike at its shops and the shortage and bad condition of its motive power.

Charleston, W. Va.

Market conditions have undergone no change in West Virginia during the past week, but a drop in prices is anticipated by some coal men if the mild weather continues much longer. The indications in the earlier part of the week were that the car supply would be good for the present week, a condition that has not existed since the first of the year; but it is too early to say that there has been a material change or improvement as yet.

Louisville, Ky.

Normal conditions are again prevailing in the local coal trade. The breaking up of the ice in the rivers, and the action of the railroad companies in relieving the congestion have brought about this condition, together with the letup in the heavy demand for coal. While business still continues brisk, both in the retail and the wholesale lines, everything is moving along smoothly. The difficulty which the commercial institutions were experiencing in securing enough fuel to keep steam plants going has been remedied, and manufacturers and office tenants have ceased to complain.

Memphis, Tenn.

The weather conditions in this territory have materially changed since our last issue, the temperature going up to as high as 60° the last few days. This has caused a surplus of domestic coal to accumulate in the city.

The wholesale end for steam coal has continued stiff and we have experienced some difficulty in being able to get a supply sufficient to take care of our steam contracts. The mines have held firm on their advanced price, and shown their wisdom in this matter, as their work has been limited only by the car supply.

West Kentucky prices are as follows:

No. 1 lump	$1.50@1.75
No. 2 lump	1.15@1.35
Nut	1.10@1.25
Mine-run	0.85@1.00

The demand for screenings has been something unusual the entire season, it being impossible to secure enough fine coal at any time to take care of contracts.

The Cahaba and Jellico fields are all crowded with orders, and prices range: Jellico, $2@2.50; Cahaba, $2.75@3.25.

Nashville, Tenn.

Prices are not quite as stiff as they were, but the demand for coal is good, and car service is, if anything, worse than it has been. This, in a measure, has kept prices as high as they are.

Quite a few inquiries have been made for foreign shipments after Apr. 1, but hardly anything before that period. There seems to be quite a difference of opinion in regard to the strike on that date, although many people who claim to be fairly well in touch with the situation contend that there will be none. The demand for screenings, though probably not as strong as heretofore, is still fairly good.

The prevailing prices in the West Kentucky field are as follows:

Lump	$1.35
Nut	$0.95@1.05
Screenings	0.30@0.40
Mine-run	0.90@1.00

Chicago

There is an upward trend in Chicago coal prices, which dropped from 25 to 35c. per ton last Monday and Tuesday, but recovered from the loss with a bound on Wednesday.

One of the chief features of the market has been storage-coal buying. The Burlington road took 4000 cars of Eastern coal, paying $1.10@1.20 for ¾-in., with the average price ranging in the vicinity of $1.15. Smokeless coal is firm at $1.25 at the mine for mine-run, with lump and egg hard at $2@2.25. Anthracite shipments have been just as heavy as the productive capacity of the mines and the carrying capacity of the railroads would permit.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.62
Egg	2.62
Steam lump	$2.37@2.57
Screenings	1.97@2.07
Springfield:	
Domestic lump	$3.05
Steam lump	$2.32@2.42
Mine-run	2.12@2.22
Screenings	1.82@1.97
Clinton:	
Domestic lump	$2.57
Steam lump	$2.22@2.32
Mine-run	2.17@2.27
Screenings	1.87@2.00
Pocahontas and New River:	
Mine-run	$3.25@3.55
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.65@4.75; byproduct, egg and stove, $4.95; byproduct nut, $4.75; gas house, $4.90@5.

Indianapolis

A week or more of moderate weather previous to the snow storm has not lessened the demand for coal at Indiana mines, practically all of which are operating full time. Most of the present output is for storage. The dealers have in their yards almost enough for their trade until Apr. 1, when a suspension is looked for.

The result of this wage scale controversy is a demand for coal at higher prices through February and March by the consumers who want it for storage. The sale of such coal nets the operator a far better profit than if an agreement had been reached on a wage Feb. 1.

Minneapolis—St. Paul

The coal business in the Twin Cities has taken a decided slump during the past 10 days as the mild spring weather has affected the wholesaler and retailer alike. Many orders which were placed with the wholesalers during the latter part of December and in January are reaching destination and this condition, together with the mild weather, has put a damper on the dock and all-rail business. Except for the fact that the wholesalers still have on their books a considerable number of unfilled orders they would be doing practically nothing.

The strike proposition does not seem to scare the smaller manufacturer o. steam user much, but undoubtedly they will be in the market during next mont and will want enough coal to carry them over for 30 or 60 days. Owing to the demand of the large manufacturing plants for coal in 100-ton lots at the mines, and on account of the poor demand here, prices have taken a decided drop.

St. Louis, Mo.

Market conditions are practically unchanged, and indications are that there will be no radical change until perhaps after Mar. 5. There has been a marked increase in the amount of railroad tonnage placed during the past week, while at several points on the Illinois Central the entire outputs of the mines are being stored on the ground adjacent to the mine, and this is giving work on an average of five days a week to the miners.

Storage coal for commercial purposes is not as much in demand as it was two weeks ago. As a matter of fact, some of the large buyers are hesitating before placing orders, expecting there will be a surplus tonnage on the market the latter part of March if the weather gets warm. There is little storage demand from the country, and indications are that the last week in March will witness a heavy demand by those who are taking a long chance and waiting for the market to break.

The prevailing prices, which are very uncertain, as they change from day to day, are about as follows:

Franklin County	
Lump and egg	$1.85@2.00
No. 1 nut	1.75@1.85
No. 2 nut	1.60@1.70
No. 3 nut	1.35@1.50
2-in. screenings	1.00@1.10
Carterville	
Lump and egg	$1.65@1.75
No. 1 nut	1.50@1.60
No. 2 nut	1.35@1.45
No. 3 nut	1.15@1.25
Screenings	1.00@1.10
Mine-run	1.25@1.35
No. 1 washed	1.80@1.90
No. 2 washed	1.50@1.60
No. 3 washed	1.25@1.35

Spokane, Wash.

The coal situation in Spokane remains quiet, few sales either more or less than usual being made. The spring appears to be here, and warm weather is prevailing. No change has been noted in the prices of standard coals since last November. Local yards have a good supply on hand, and are receiving small shipments from the mines every week.

Salt Lake City, Utah

During the past week there has been an increased demand for coal, owing to the recurrence of winter weather. Beginning with March it is reported that the price of Wyoming coal in the Salt Lake market will be reduced to the same level as the Utah product. For the past two years it has been slightly higher. It is not known whether the reduction will be made in the freight rate or in the price of coal at the mine.

The prices of Utah coal follow: Lump, $2.40; nut, $2.15; slack, $1.25.

Portland, Ore.

There is no change in the situation here, the demand for coal continuing light on account of the mild weather. This has been a dull season for the fuel dealer, the only cold spell occurring early in January and being of short duration. As a consequence, not only coal dealers, but wood dealers as well have had rather poor business here during the winter months.

Production and Transportation Statistics

The Virginian Ry.

Total shipments of coal over the Virginian Ry. for January were 316,766 short tons as compared with 258,869 for the month previous. Strikes now in effect on this road are seriously crippling the service.

The Car Situation

In the two weeks ended Feb. 14, the surplus of coal cars decreased from 14,042 to 11,464, and the box car surplus decreased from 12,781 to 11,426. Miscellaneous car surplus showed little change, and the flat car surplus was slightly smaller.

Foreign Markets

Sweden

Concerning the effect the possible strike of the British coal miners on the situation in Sweden, the *Daily Consular and Trade Reports* says:

It is conceivable that the labor troubles in England might affect the situation to an extent such that Sweden would have to look elsewhere for its supply, thus giving a possible opportunity for the introduction of American coal.

Coal constitutes nearly 10 per cent. of the total imports into Sweden. About one-fifth of this fuel is entered at Gothenburg, which port and Stockholm are the principal import places, Malmo and Gefle coming next. The total import for the last three years for which figures are available has been, in tons: In 1907, 4,146,785; in 1908, 4,427,507; in 1909, 4,084,055. It was practically all from Great Britain.

The production of coal in Sweden is less than 7 per cent. of the consumption of the country, the output in 1910 being 302,800 tons. [A list of Gothenburg coal importers may be obtained from the Bureau of Manufactures.]

Great Britain

Business in the British markets is being conducted within restricted limits due to the uncertainty in the labor situation. The prices at which purchases can be made are governed, not so much by the relative value of the different grades, as by the condition of the consumer.

Approximate quotations are as follows:

Best admiralty, large	$4.56
Second admiralty, large	4.20
Best dry, large	4.32
Second dry, large	4.08
Black veins, Cardiff shipment	4.26
Western valleys, Cardiff shipment	4.20
Eastern valleys, Cardiff shipment	3.96

Financial Notes

The net income from the operations of the Delaware, Lackawanna & Western coal department for the year 1911 was $3,490,085, or $108,822 more than for 1910. Expenditures during the year on coal properties aggregate $747,265. Cost per ton of mining was about 2c. more, due to the necessity of working thinner seams.

Total earning of the Byproducts Coke Co. for 1911 were $479,746. Deducting depreciation accounts and dividends the total undivided earnings Dec. 31, 1911, were $169,051. From these earnings a dividend of $3 a share, amounting to $90,000, was declared, payable Feb. 15, 1912, and a bonus given the employees of $6942.

The newly organized Brier Hill Steel Co. of Youngstown, Ohio, has some valuable properties. Included among these are blast furnaces, rolling mills, ore properties and a good vein of coking coal. The blast furnaces, coke and ore properties are valued at $6,652,000 and the mill properties at $1,860,000. The total resources of the company are given at $15,000,000, with a cash and inventories account of $1,051,000.

It was announced in Denver on Feb. 16 that negotiations pending for several months had been concluded for the readjustment of the finances of the Denver, Laramie & Northwestern R.R. and its allies, the Denver-Laramie Land & Iron Co. and the Colorado-Wyoming Coal Co. The plan calls for a reduction in the total debt (funded and floating) to not over $1,000,000 through a reduction in the floating indebtedness by $1,000,000.

Stock of the Lehigh Valley Coal Sales Co., which sold recently at 192, advanced to 207 on the Curb. This is the stock representing the coal-mining properties segregated by the Lehigh Valley R.R. Co. Within two weeks the price has been down to 180. The Lehigh is almost as strong in the coal business as the Lackawanna, and stockholders are making comparisons between Lackawanna Coal at 350 and Lehigh Coal at 207, as showing the bargain possibilities in the latter.

Earnings of the Colorado Fuel & Iron Co. are running very much at the rate of last year, which showed a surplus of $1,260,000 after all deductions. Colorado Fuel preferred is selling around 115, with more than customary activity of late. By the time the company's charter expires, which will be on Oct. 21 of the present year, the accumulated unpaid back dividends will total about $1,320,000, or 64 per cent. of the entire par value of $2,000,000 preferred stock outstanding. Just what sort of a deal the preferred shareholders will get when the time comes for renewing the charter it is difficult to say; in fact, the matter of whether the company's charter will be renewed or the company reincorporated has not been settled.

West Virginia Statistics for 1911

By John Laing*

Excerpts from advance sheets of the chief mine inspector's report for the fiscal year ending June 30, 1911. The encroachment of the byproduct oven into the coke industry is responsible for a falling off in this branch. Total coal production for the period was 54,033,186 gross tons, a gain of 2.09 per cent. Tables giving complete statistics will be published in a later issue.

*Chief of Department of Mines, Charleston, W. Va.

Briefly stated, the mines of West Virginia reported for the year ended June 30, 1911, a total output of 53,733,186 gross tons of coal, and to this amount we have added 300,000 gross tons to cover the various small operations throughout the state, which are not required to report to this department; this makes a grand total of 54,033,186 gross tons of coal produced at all the mines in the state. This is an increase of 1,109,478 gross tons over that for the year previous, or a gain of 2.09 per cent.

It is gratifying for this department to be able to report an increased production in coal, taking into consideration the condition of the markets and business in general throughout the country during the past year. I believe that, if general business conditions continue normal during the present year, our production will far exceed last year's output and each year will continue to exceed the previous one until within the next seven or eight years we will be the leading bituminous coal-producing state in the Union. We are now the second largest producer, Pennsylvania being first.

The total value of the coal produced (54,033,186 gross tons) at the mines, was $52,952,522.28. The value of the coal loaded on railroad cars and shipped from the mines was $46,870,788.30, practically all of which was consumed in other states, which means that the coal industry brought this amount of money into the state of West Virginia.

On account of market conditions, we had a reduction in the coke production, it being this year 2,694,047 net tons, as compared with 4,217,381 last year, or a decrease of 1,523,334 net tons. Manufacturing of coke at the mines in this state is gradually being discontinued, as the various byproduct plants throughout the country can manufacture coke, even after shipping the coal from the mines to their plants, much cheaper than it can be produced at the mines; therefore, as above stated, coke burning at the mines is gradually being dispensed with. This, however, in no way interferes with the production, as the West Virginia coals are much in demand at the byproduct plants, owing to their superior quality for coking purposes.

The coke at the ovens this year was valued at $5,037,867.89. Practically all of this was consumed in other states, which means that the coke industry brought this amount of money into West Virginia during the year.

Accidents

We regret that there was an increase of 12 fatal accidents this year as compared with last, the total this year being 332. The increase is due to two serious accidents, one being the explosion of the Ott No. 20 mine, operated by the Davis Coal & Coke Co., Apr. 24, 1911, in which 23 men lost their lives; and on Dec. 31, 1910, there were 10 men killed in a runaway on an incline at the Lick Branch Mine, operated by the Red Jacket Coal & Coke Co., making a total of 33 men being killed. This shows conclusively that accidents from general causes, such as falls of roof, mine cars, etc., were not so great this year as last, which indicates that extra precaution has been taken by the operators, managers, superintendents, and foremen, notwithstanding the fact that more coal was produced. All of these accidents occurred at 223 mines, employing 28,533 persons and producing 26,966,844 gross tons of coal, while at the remaining mines there were produced 27,066,342 gross tons of coal, without the loss of a single life.

There were 179,710 tons of coal produced per each fatality, and a total of 819 nonfatal accidents, which is a decrease of 123, as compared with last year.

Quite a number of improvements have been made at the various mines on old plants, as well as opening up and reequipping new mines. During the year there were 21 new mines opened which have just begun shipping and which will materially add to the production for the coming year.

Men Employed and Labor Troubles

There was an average of 70,644 persons employed in and around the mines during the year, including 2868 coke workers. This does not include the mine superintendents, managers, foremen, fire bosses, store and office help for whom it would be safe to add 2350 persons, which would make a total of 72,994 directly connected with the operations of the mines in this state.

Included in this total of 70,644 there were 30,044 white Americans and 11,950 negroes, the balance being composed of Italians, Hungarians and other foreigners, who do not speak the English language.

We are pleased to report that the production in this state has not been held down on account of strikes, as there have only been eight of these throughout the entire state during the year. These affected six different mines, but were only local in each case and were amicably settled within a few hours after they occurred.

Examinations

Since the inauguration of the system of examining applicants for certificates to act as mine foremen and fire bosses, up to the close of the report for the year ending June 30, 1911, we have examined 2203 persons, 1243 of whom were successful, as follows: 627 first-class certificates; 566 second-class certificates; 50 fireboss certificates.

We believe that these examinations have done much good for many reasons. It has put the men holding these positions to thinking and studying mining conditions, which better qualifies them to act in these very responsible positions. As time goes on, we will, no doubt, have the advantage of a gradual improvement in the efficiency of men in such positions. The younger men, who are now working in and around the mines and who are aspiring eventually for such places, will educate themselves more thoroughly, knowing that when the time arrives and a vacancy presents itself, they must be in a position then to pass the examination; they will not then be permitted to accept the foremanship of a mine and then be taught the duties which they will have to perform, but will be prepared from the beginning, and when they are given such positions their advancement to still higher ones will come more rapidly. The men engaged in mining realize that the time has come when persons in charge of the lives of the men in and around the mines have got to be men of efficiency as well as of good moral character.

According to Edward W. Parker, of the United States Geological Survey, West Virginia possesses a larger supply of coking and other high-grade coal than any other state in the Union, except Pennsylvania. In 1910, West Virginia produced 3,803,881 short tons of coke valued at $7,355,233. Alabama produced 3,249,027 short tons valued at $9,165,821. In quality, the West Virginia coke is better than that of Alabama, but the average price of Alabama coke in 1910 was $2.82, while that of West Virginia was $1.93.

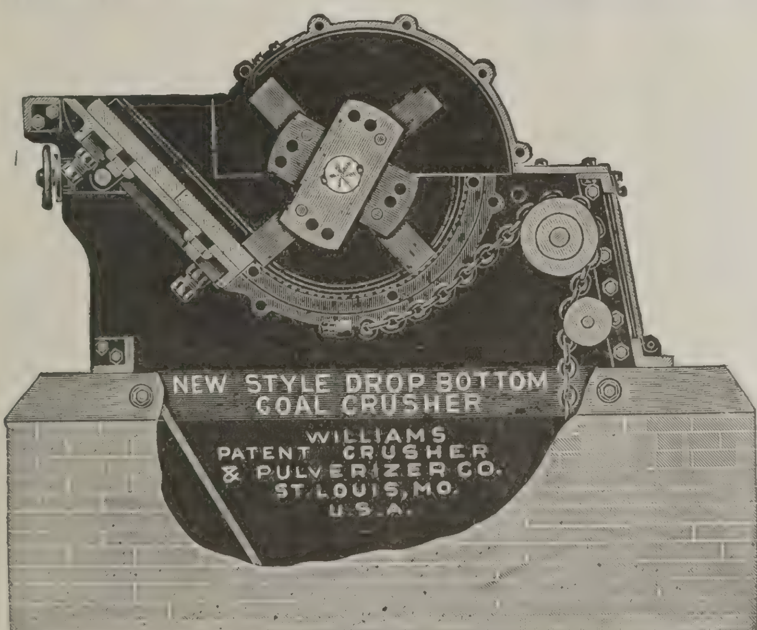
Bituminous Coal Crushing

How It Is Done Better And More Economically By Williams ' oal Crushers



It is a well known fact that the front half of the cage in a coal crusher will wear much faster than the back half when crushing a hard, bituminous coal.

Hence, we make the cage of the **Williams Patent Hinged Hammer Coal Crusher** in sections, so that sections of the cage can be interchanged, or as many sections as necessary be renewed on occasion, whereas if the cage were in one piece, the entire cage would be destroyed should the front half become worn.

This feature, combined with the **Hinged Hammer** principle and with the design that makes every part adjustable not only to itself and wear but also to every other part, is the reason why the **Williams Crusher** can crush more coal with less power and lower cost of maintenance than any other crusher on the market. Catalog No. 5 with full particulars sent on request. Write.

Manufactured and licensed under 87 separate and distinct patents. More than 2,000 in daily use.

COAL AGE

Vol. 1 NEW YORK, MARCH 9, 1912 No. 22

THE English coal strike is the inevitable result of economic conditions in Great Britain. For a score of years the British people have been losing in their desperate duel with Germany for commercial supremacy. At the beginning, England was everything—Germany nothing. Today the Germans are leading and that country's success is due to the health, energy and education of its workingmen, brought about by a broad, carefully planned governmental policy.

The Germans have old-age pensions, accident indemnity, sick benefits and rigid regulation of dangerous employments. All these have advanced, not retarded business. The workers in Germany are housed in comfortable dwellings, eat good food, have pleasant surroundings and the opportunity to educate their children. As a consequence, German labor has maintained a normal consuming power, and exhibits high efficiency in production.

England has permitted her working population to deteriorate in slums; has pretended to believe that the strength of a nation is in her banks, palaces, armaments and battleships. "Every man for himself," has been the essential of English policy. Germany has understood that real strength lies in her men who work with their hands.

Before long, the United States, following close in the footsteps of England, will have to match forces with Germany and Japan, and unless there is a change in our present system, the struggle will be as unequal and as unsuccessful for us. We haven't, as yet, eight million people on the destitution line as has England, but the almshouse and public-hospital population of New York is increasing from 12 to 14 per cent. every year, while the total population of the city is only increasing at the rate of 3 per cent.

Every other man we meet has some solution for present social problems. When a strike occurs, we say it is due to the high cost of living—miners and laborers can't earn enough to purchase daily necessities. Suppose this is true. What are we going to do about it? Inflicting fines on the officers of a company because they won't compete with themselves is not a solution, for the public after all pay such charges. If we put these same men in jail, others will take their places at the helm of business, and the stern, relentless demands of our present industrial system will compel them to follow in the footsteps of their predecessors, whether they want to or not.

The whole matter has been one of evolution. Starting with a hundred small companies, we combined here and there until there were only fifty. These fifty were consolidated into ten; the ten became two, and at last the two merged into one great business machine, bigger oftentimes than the government itself. Each stage of this combining process was marked by the issuing of additional securities, based upon the saving of expenses and increase of income to be achieved by the consolidation. Then, in order to furnish dividends and pay interest on the enormous mass of securities, prices of products are put up, wages held down, and the majority suffer to benefit the "few."

Now, the mistake we make is in blaming the "few," rather than in condemning and correcting the system. It was true, perhaps, a century ago, that a man directed his business, but, today, business runs the man, and if he doesn't obey the precepts laid down for his guidance, business will remove him and a more obedient servant will be employed.

Just so long as we can take a value and legally capitalize it five- or ten-fold, just that long will business compel its servants to debauch legislatures, and cause many people to believe that it is as proper to bribe an assemblyman as to tip a waiter. The certain result of present methods is to increase poverty on one side and superfluity on the other. Strikes will occur with increased frequency and enlarged scope until the government first, and then business, are reformed along lines which will bring equality in a broader sense than now.

Until we prohibit the legalized capitalization of "latent value," we will not have taken the first essential step to correct present social evils. Too many are waiting for the next generation to deal with a problem of today. Evolution does not go backward. Competition such as we have had in the past will not return. Just as serfdom ran its course and gave way to feudalism, and the latter to capitalism, so must capitalism be supplanted by a system less designed to swell private fortunes and encourage personal greed. This is the age of man, not primates. We should be as willing to concede economic as geologic facts.

The Problem of Mine Timbering

By R. B. Woodworth*

Various materials of construction are here discussed with regard to their suitability for use in different kinds of mine supports and some conclusions are reached as to their relative values for this purpose. The third of a series of articles on mine timbering with special reference to the use of steel.

The right use of the materials of construction proceeds from an intelligent appreciation of the physical qualities of those materials, their respective advantages and disadvantages and their peculiar fitness for the service at hand. Each of the usual materials of construction has its right place and its right use about the mines. Economic waste, however, attends the use of a material in any service when some other material is better suited to that service.

In general these materials of construction fall into two classes. On one side stand the heavy permanent materials of low tensile strength but high resisttance to compression and crushing, for use in situations where mass is wanted; and on the other are the lighter materials of high tensile strength, fitted to carry large loads over wide spans with the minimum ratio of dead weight to external loading. Brick, stone and concrete belong in the first class; wood, iron and steel in the second. With the technical aspects of the mine timbering problem clear in our minds, let us pass to the consideration of the fitness of these materials for mine timber uses.

We need here to consider only the best kinds of wood; white oak, long leaf yellow pine, short leaf yellow pine, white pine and spruce. Wood is a material of wide distribution, easily framed and fitted for service, with moduli of elasticity about equal in tension and in compression, permitting satisfactory use as beams and girders to carry heavy loads over wide spans, or again as columns to carry heavy loads on long lengths with small area; and it permits of installation by manual labor alone. The defects of wood are its low shearing value, its liability, in its natural state, to decay and to the attacks of insect enemies, and its low resistance to fire.

Universal Use of Wood

Wood is the universal material for cheap construction and has proven its fitness for mine timbering purposes by long years of use, even in circular shafts for which it is, of all places perhaps, least suited. It loses its place in mine timbering only on the advent of something better, only where its capitalized cost, based on its durability, is less than the capitalized cost of substitutes based on their durability. If it were durable under the alternating conditions of temperature and moisture which obtain within the mines, and if it offered security against fire and the consequent destruction of life and property entailed thereby, no one could ask for better material.

Stone is a heavy material of great compressive and crushing strength, but low in tensile value; a good resistant to fire. Within the mines it would be structurally suitable for shaft lining were it not for the expense of masonry construction and the difficulties of placing it in the process of sinking. The use of waste rock, taken down in the process of mining, for building the side walls of headings and for large piers under tender roofs has every thing in its favor and its skillful use means much in the way of true economy. Such pack walls, as they are called in England, have much to commend them as the utilization of a by-product. They serve to carry the direct load at the sides of the headings. But this waste rock offers no opportunity for use as roof supports, unless laid in mortar and arched. The more extended use of waste rock in the mines of the United States might avoid the use of more valuable materials and this subject deserves the attention of mine operators.

Brick is an excellent fire resistant; of medium value in compressive strength and crushing value; without much tensile strength; excellent for side walls to carry roof supports and so employed to great a extent in permanent headings of English mines. It is ideal for circular shaft lining if the cost permits, not so good for elliptical shafts, and not at all adaptable for rectangular shafts. It resists bending stresses only when in arch form. It is used within a few mines in the United States for side walls in pump houses and fire zones and also for stoppings in air courses.

Concrete

Concrete, like stone, is high in compressive strength and shearing value, but low in tensile strength; it is also a good fire resistant and, therefore, eminently fit for lagging purposes. It makes an ideal lining for elliptical shafts. Concrete must be mixed with care and intelligence, and is often defective. If the ingredients are properly proportioned and the batch well mixed, it is a good material of construction for certain uses, but it is not adapted to resist bending stresses or alternating bending, tensile and compressive stresses such as occur in mine timbering. Concrete, moreover, needs reinforcement by steel in order that its bulk may not greatly increase the amount of excavation required.

Recently, experiments have been made, and several patents taken out in connection with the use of concrete for gangway supports, to replace steel or wood. I hold no brief against concrete, just as I hold none against any other modern material of construction; it has a

Steel-framed Gangway, Mine No. 7, Sturgis, Ky.

*Engineer with the Carnegie Steel Co., Pittsburg, Penn.

Note—Paper read before the Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.

place that it alone can rightly fill, but its proper use is not as roof or gangway supports. Given a rectangular white oak or long leaf yellow pine beam of any span, width or depth, a plain concrete beam of equivalent strength must be 2.83 times as deep for the same width or 8 times as wide for the same depth; while a steel beam of equivalent strength may be 3.65 times shallower for the same width or 13 1/3 times narrower for the same depth. If reinforced concrete is used, the beam of equivalent strength and the same depth must have as much steel in tension reinforcement as there would be in the bottom flange of a steel beam of the same depth and strength.

SLOPE AT MINE NO. 8, WEST KENTUCKY COAL CO.

[These comparisons are evidently made on the basis of an allowable tensile stress of approximately 100 lb. per sq. in. for concrete; 800 lb. per sq. in. for wood and 10,500 lb. per sq. in. for steel, but it should be remarked that it is almost without exception a mistake to figure on concrete taking any tensile stress whatever and a concrete beam without reinforcement on the tension side is poor and unsafe design. It should also be remarked that the use of concrete arches is not here considered—a form of construction to which concrete is well adapted.—Ed.]

Cast iron was tried out years ago for roof and gangway supports and was abandoned, just as the cast iron beam, once common in building construction, has passed into history. This material is well suited to resist direct compression but not tensile stress or cross bending. The cast iron segment is, however, the standard unit for lining circular shafts abroad and subaqueous tunnels everywhere, with, however, the possibility that 25 years from now it will be driven out of even these fields by structural steel or a combination of structural steel and concrete.

STRUCTURAL STEEL

Structural steel is the modern universal material of construction. It is a malleable alloy of iron, carbon and manganese with moduli of elasticity high and about equal for tension and compression; shearing value three-fourths the tension value, and, therefore, relatively high, so high indeed that it need seldom be taken into account. It is a homogeneous material; easy to obtain, fabricate and erect; suited to resist tensile, compressive, cross bending and shearing stresses, either continuous or alternating, single or combined. It is in everyday use in the building of structures above ground and is a most suitable material with which to replace wood in the timbering of excavations underground for the same reasons that explain its use in place of wood above ground. Steel is most nearly like wood in its physical properties and, therefore, best suited to be its substitute. It is a material which long experience, both in the United States and abroad, has demonstrated beyond question to be economical for use in mine timbering as compared with any other material which has been used for that purpose; and it is economical in the sense that its qualities in regard to endurance, fire resistance, and offering the greatest strength for the least weight, are such as to enable it to show a comparatively low cost when computed on the ground of ultimate expenditure.

The substitution of steel for wood is simply the substitution of a material of great strength and endurance for a similar material of less strength and endurance. The substitution of steel for wood in mine timbering means no significant change in general design, and the simplification of details rather than modification of their essential character. Structural steel is a most flexible material. The forms of wood construction customary in mine timbering can be duplicated exactly in steel; a set of steel gangway timbers can alternate with wooden timbers; a set of steel mine shaft frames may be alternated with wooden frames; wood may be taken out and steel

DRIFT NO. 2, ROBY COAL CO., ADENA, OHIO

put in its place; steel may be taken out and wood put in its place; there are no other materials of construction permitting such easy interchange. Wherever bending and tensile stresses are to be resisted steel and wood find place, with this difference, that the use of steel avoids all those elements of economic waste to which wood is liable and with the further merit, as inferred from experience, that the use of steel within the mines means less excavation and better ventilation.

There is some difference in the behavior of wood and steel under service conditions. Steel deflects gradually under pressure and will bend greatly before fracture, and even when stressed past its elastic limit, may be taken out, straightened and replaced, whereas wood, in addition to the longitudinal separation of the fibers, breaks also transversely. This is why timber with long fibers is better than that with short, and why long-leaf yellow pine makes the most excellent wooden mine timber. The difference in behavior of steel and wood is of little practical importance in the timbering of permanent headings, but does come into account in the use of steel for props, and in other cases of possible re-use.

Steel and wood are alike, moreover, in that both are gnawed by the tooth of time. Wood rots; steel corrodes. The protection of steel from corrosion, however, is a simple matter and inexpensive; the preservative treatment of wood, on the other hand, if done well, costs as much, or more, than the raw material itself.

As a result of this examination into the several types of mine timbering, the stresses in their members and the physical qualities of the materials in common use, we can now tabulate these types of framing with the materials most suitable for use in them:

Circular shaft framing	Brick, concrete, cast iron or steel
Elliptical shaft framing	Concrete or steel
Rectangular shaft framing	Wood or steel
Square timber sets	Wood or steel
Triangular timber sets	Wood or steel
Gangway supports	Wood or steel
Roof supports	Wood or steel or pack walls, etc.
Lagging	Wood, steel, concrete or brick

STEEL ROOF SUPPORTS, MINE OF SPRING VALLEY COAL CO., SPRING VALLEY, ILL.

Earthquakes and Mine Explosions

Special Correspondence

A brief resumé of interesting discussions at the conference of the International Association of Seismology. Radio-active products the source of the earth's heat. Formation of mountains and valleys. The earthquake and the pendulum. Correspondence of seismic unrest and mine explosions.

Reading the editorial "Danger Periods In Mines" in COAL AGE, Dec. 16, page 317, recalls to mind the report of the three days' conference of the International Association of Seismology, held in Manchester, England, last July, when the governments of seventeen countries, including the United States and Canada, were officially represented. Many interesting theories were discussed, and since the question of the possible association between seismic unrest and mine explosions is now claiming the attention of experts, it may be interesting to present a summary of some of the matters then discussed.

Prof. Schuster, in his presidential address, recalled how in youth we were taught that the earth, once a molten and fiery globe, had gradually cooled down, leaving the inside still hot but gradually cooling and contracting. This contraction of the nucleus was for a long time considered the primary cause of geological dislocations. How do we stand at present? In the breaking up of radioactive products we find a source of heat, which, if the amount of radium and thorium in the interior of the earth is not decidedly less than that found near the surface, will not only balance the earth's loss of heat by radiation but actually increase its average temperature. Though reasons might easily be found why the surface layer of the earth might be richer in radio-active products than the core, we are nevertheless driven to the conclusion that the earth is now, and has been for a long time, in thermal equilibrium and that shrinkage by cooling does not account for any of the more recent displacements.

The causes of such inequalities as valleys and mountain chains, and the more general depressions and elevations that cause the distribution of land and water over the globe, have long interested geologists and mathematicians, but the wider discussion of the stability of the whole structure on which we live has only recently come into prominence. Only recently, Prof. Love has treated the problems of geophysics with masterly ability and lucidity, while the work of Prof. Heeker has brought to light the curious result that the earth appears to resist a change of shape less in a north and south (polar) than in an east and west (equitorial) direction. After referring to this fact the president said that Prof. Love, having failed to account satisfactorily for such effect in other ways, suggests that the lack of symmetry in rigidity was apparent only, and that the observed effects are due to the attraction of the tide wave in the

North Atlantic and its accompanying excess pressure on the sea bottom.

Among the papers read was one by Prof. Wiechert, describing the times taken by earthquake waves or seismic disturbances to radiate to different parts of the earth's surface. The later discussion of this subject led to the suggestion of a theory regarding the influence of the material forming the earth. It was stated that the earth can be divided into three zones or layers, through each of which the velocity of propagation of the disturbance follows a special law. The inner zone or nucleus was described as probably chiefly composed of metal, say nickel or iron. The first or outer layer was estimated roughly as being 750 miles, and the second layer about 1000 miles thick.

The Formation of Mountain Ranges

In a paper treating on the formation of mountain ranges, Prof. Reid, of the United States, referring to the view that these are due to volcanic action, stated that recent research has shown that such theory is insufficient. Another theory has been advanced claiming that they are the result of side thrust or tangential pressure, and still later observations ascribe their formation in part to gravity. The formation of mountain ranges it was urged must be explained by the expansion of material forming the earth. In support of this theory it was argued that it is impossible to increase or decrease what may be styled the equilibrium quantity of any segment of the earth, and if this be true the formation of ranges must be taken as evidence of the upward expansion of the material at that point, and a general decrease in density.

The upward force creates strains in the adjacent crust, and when these strains become sufficiently great they cause a break accompanied by a greater or less shock and a fault is developed at that particular point. The phenomenon is often followed by an earthquake. As the result of his observations, Prof. Reid found that earthquakes do not occur at the same fault line, except after long intervals of time; but if a number of severe earthquakes occur in quick succession the movements take place at different fault lines. Referring to the energy of earthquakes Prof. Reid said the intensity and area of the shock may not correspond, and it is of the utmost value to be able to estimate the quantity of energy manifested. Earthquakes differ enormously in the quantities of energy they develop. The Jamaica earthquake a few years ago (1906), although of great force near its origin, was limited to a small area and the amount of energy liberated was correspondingly small. The method used by Prof. Reid to estimate the energy developed by an earth shock depends chiefly on ascertaining the area of the surface of the earth affected, which involves practically the calculation of the area of any defined surface of an ellipsoid. The square of this area gives a number that is proportional to the amount of energy developed.

The Milne Horizontal Pendulums

The interest of readers of Coal Age will center, however, in the contribution of Prof. F. Napier Denison on "Horizontal Pendulum Movements In Relation To Certain Phenomena," giving the results of observations carried on upon the Pacific coast, for a series of years. It was stated that in the autumn of 1898 a Milne horizontal pendulum, swinging east and west, was installed at Victoria, B. C. Prof. Denison became deeply interested in observing certain wanderings of that pendulum, and has since 1907 closely observed the movements of another pendulum, 500 feet from the first and set to swing north and south. A careful comparison of the curves plotted daily for 1907, showed that each of these pendulums had a general tendency to move in the direction of the greatest air-pressure, and it was noticeable that this general direction was northwest and southeast. The presence of certain pronounced long-period undulations were also detected, possessing marked rhythmic characteristics too great to be caused by local meteorological conditions. Prof. Denison found that the east-west pendulum reached a maximum eastward movement during the summer months and a maximum westward movement in the winter. In addition to these semi-annual movements, annual movements were noticeable. The pendulum curves compared with seismic curves show in general over a period of 12 years that the periods of minimum-quake frequency usually corresponded with maximum easterly movements of the pendulum; while the maximum-quake frequency were mostly coincident with abnormally rapid movements of the pendulum and generally in connection with the westerly maximum swing.

Mine Accidents and Pendulums

Prof. Denison further said he had studied the pendulum curves and seismic records corresponding to the dates of numerous American and European mine explosions, his object being to ascertain what correspondence, if any, existed between mine explosions, the frequency of earthquakes and the swinging of the east-west pendulum. He found that the explosions appeared to occur more frequently during the months of extreme pendulum movements, and particularly at or near to the westerly swing. For the year 1904, the pendulum curve shows very small annual inequality, maintaining that year a close proximity to the normal line, and few earthquakes were recorded, while there was a remarkable absence of mine explosions. It was further stated that the same correspondence between extreme pendulum movements and frequency of mine explosions was to be noted in the curves relating not only to the winter months, when it might be expected, but also to the summer months. The correspondence of times of earth tremors with times of frequency of mine explosions seems to bear out the theory that the earth is undergoing great strains, at such times, and it is possible that the coal measures are affected to such an extent by those strains that gas may be liberated more freely, being assisted by the disturbance of the strata to make its way into the workings of the mine. Prof. Denison even suggested that it may be possible, after further study, by watching the movements of the pendulum to warn mine operators, so that special inspections of their mines may be made at certain so-called "periods of danger," when there seems to be a possibility of the occurrence of mine explosions.

In the view of Prof. Denison, Victoria, B. C., is most suitably situated for making such observations, and the generous support of the International Association of Seismology was promised by its president, Prof. Schuster.

The New Coke Plant at South Bethlehem

A new coking plant is being erected near South Bethlehem, Penn. A German company owns the plant and has done all the engineering work, though the plant, when completed, is to be operated by the Lehigh Coke Co. The plant is to consist of 8 batteries containing 75 ovens each, a gas-holder, byproduct plant, coal storage yards, and storage house for the liquid byproducts.

All apparatus and machinery is to be operated automatically so as to reduce labor to a minimum. The work of installing the first 300 ovens was begun last November; they will be finished and running within a year and the remaining 300 started. Each oven is to have a charge of 13 gross tons and the 300 together will require 4300 tons per day.

The plant is to consist of two parallel lines of ovens with heavy concrete foundations, separated by six railroad tracks, which are to be used for hauling the coal and coke. Each line of ovens is to be equipped with 4 batteries and each battery with a stack from 225 to 240 ft. high. Coal crushers will prepare the coal and electric conveyers will carry it overhead to the ovens where electrically-driven carriers will charge the ovens, raising and lowering the oven doors to charge the coal and draw the coke.

Faulty Power Plant Design

By E. L. Cole

Inefficient designs of power plants often waste money, cause breakdowns, accidents and fires. Many collieries are uncertain and uneconomical in operation because these facts are not understood or considered.

During a recent trip through the coal fields, I was amazed at some of the errors made in designing colliery power plants. And what was more surprising, was that the errors were not confined to the plants of the smaller coal companies. At the larger ones also was much erroneous designing.

In Fig. 3 is shown the position of a power station, containing two 100 kw., 250-volt direct current generators, operating at a speed of 220 r.p.m. A peculiar error at this plant was that of locating the generators at a point three-fifths of a mile distant from the boiler house, and at an elevation 85 ft. lower than the steam generators. A careful observer could see at a glance the danger to be apprehended from a body of water entering the steam chest and creating havoc. The attendant volunteered the information that the engines had suffered from three cylinder accidents, in the course of fifteen months, and that considerable trouble was always experienced when the steam pressure fell below 70 lb., as it frequently did, at times when all the pumps were running to rid the mines of the large volumes of water entering during the rainy season.

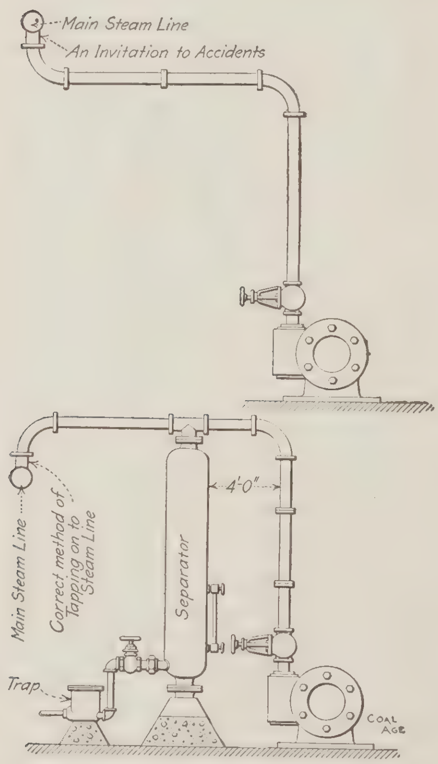

Fig. 1. Ill Planned Steam Piping

Needless Wiring and Piping

The reason assigned for locating the power house at such a peculiar location, was that a steam line was available, which had hitherto supplied two air compressers which were no longer in service. Whoever designed this power plant, seemed to have given little or no thought to his work. As shown in the plan of Fig. 1, 85% of the electric energy which was being generated at the power house, had to be transmitted to a point beyond the boilers. Adjacent to the latter there was an ideal location available for the power plant. Had the designing of the plant been in competent hands a considerable amount of money would have been saved to the owners. The boiler and electric plants would have been stationed side by side so that a large saving in the transmission of steam would have been effected and the cylinder accidents eliminated; the length of the transmission line would also have been much less, and a large saving would have been effected in the expenditure of money for copper wire.

Faulty Foundations

At another colliery the engineer had avoided the mistake of the first designers, and had located the power plant within 20 ft. of the boiler house. Nevertheless, he was guilty of a most grevious error, as the ground where the station was located was made up of a bed of ashes 15 ft. deep, and underlying it, was a large body of saw-dust, the site having been used before the days of coal mining for a saw-mill. Fig. 2, shows this faulty installation.

The construction of the steam line, and method of tapping it as shown in the upper half of Fig. 1 was a revelation of what not to do in designing and constructing steam plants. It would seem as if the designer had deliberately invited mechanical trouble, and as a result of the poor design this power plant has a record of fourteen minor accidents and three serious ones, which caused a large economic loss to the owners, but could have been easily avoided, had the plant been located 95 ft. from the boiler house, where a solid rock foundation was available, and had the steam line been designed as shown in the lower half of Fig. 1.

Another plant was well designed, but for the fact that the designer had failed to provide an exhaust head to prevent the moisture from scattering on the nearby roof. As the plant began operation in the summer time, the omission did not seem serious, until the month of December, when a carpenter, who was repairing the roof, slipped on the ice covered shingles, falling to the ground, sustaining serious injuries. Then the owner was compelled to give to the injured workman a sum of money which would have covered the cost of several good exhaust heads, such as the market affords.

Insufficient Circuit Breaking

A visit to the next plant disclosed the fact that the designer was a good mechanical engineer, but his knowledge of electrical engineering was somewhat limited, as he had four lines running out of the power house and all were dependent upon one double pole circuit-breaker, and when trouble occurred to one line only, as it frequently does in coal mines, work was suspended in all parts of the colliery, until the transmission of current was again resumed.

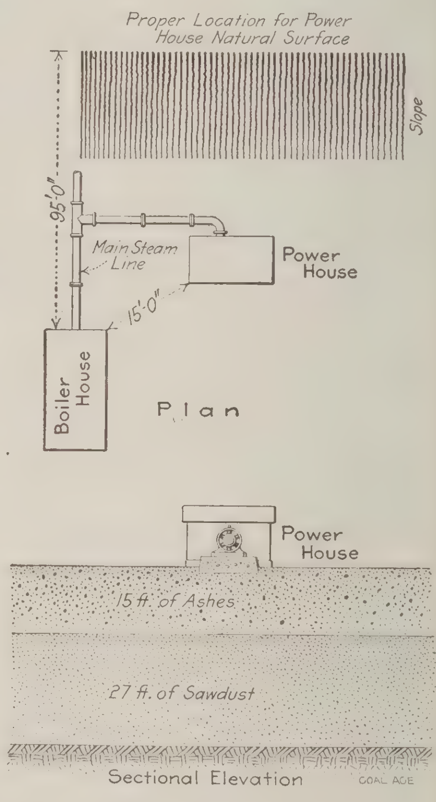

Fig. 2. A Poor Engine Foundation

Another error lay in not providing a circuit-breaker for a transmission line delivering power to a 65-hp. motor, which actuated an 18-ft. fan. Whenever one of the locomotives threw out

the solitary double-pole circuit-breaker in the power house, the current was cut off supplying the fan so that the armature stopped revolving. The spring on the starting box of the fan motor was weak and cessation of current did not serve to enable it to throw back the contact lever from the "on" position. Consequently, when the power was reëstablished, the full volume of current was thrown into the stationary armature. This happened several times and on two occasions it burned the coils, the cost of repair being $96.

Overtaxed Wiring

I paid a visit to a large breaker and it seemed to me, that whoever had installed the electric wiring was blind to all things but first cost. The breaker contained three hundred 16-cp. incandescent lamps, and eighteen 5½ ampere arc lamps. Yet the No. 4 service lines were brought into the building without any protective tubes, being controlled by one 50 ampere, double pole, single throw, fuseless knife-switch, which was mounted in a non-fireproof cabinet, minus a door. Furthermore, all branch lines were tapped to the service lines at the main switch, the only protection afforded were three double-pole fuse boxes, which were adapted to more current than the wires should have carried. All lines had more than the standard number of lamps then permitted by the National Electric Code.

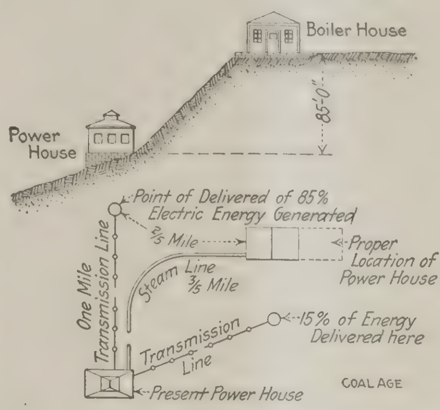

Fig. 3. Badly Located Power House

For instance three of the branches fed more than 30 incandescent lamps each, and as a result of the poor distribution, and the inadequate amount of copper wire used throughout the breaker the lighting was inefficient. In fact I saw several boys using ordinary miner's lamps to furnish additional illumination, but the most serious error was, that all lamp sockets were of the brass-shell type, and on account of the ever-present moisture, the fiber lining of the socket would readily lose its insulating qualities, and in the short period of eight months it was found necessary to replace 187 of the sockets. In consequence of the inefficient method of lighting this breaker, the lighting of coal-breakers by electricity received much unmerited criticism, due entirely to the fact that some untrained man had made a botch of a job which he should never have been permitted to undertake, for he thus introduced an extraordinary fire hazard, in an inflammable building.

I have mentioned but a few of the errors in the designing of electric equipment for the production of coal, and it would seem that the economic loss inflicted on owners would impress upon them the importance of placing the expenditure of their money in the hands of careful and competent engineers, but the trouble with many is, that while they keep an ever-watchful eye on the first cost, they seem to lose sight entirely of the expense of operating an ill contrived and inadequate plant.

The Run of Mine System in Illinois

By A. Dinsmoor

Causes that led to the strike of 1897 and the adoption of the "Run-of-mine," or "Gross-ton" system as a basis for the payment for mining. Results of the working of the system in Illinois during 14 years. Effect on miners and operators deplored. Need of mutual cooperation.

It has lately been my privilege to talk with a prominent coal operator in Illinois and with an ex-superintendent of mines, now a wholesale coal dealer in Chicago. They have given me permission to hand to the readers of Coal Age the information thus gained, upon the subject of the payment of miners by the gross ton—information that has been supplemented from other sources.

While this so called "run-of-mine" system prevails in the South and Southwest, in West Virginia, and to some extent in Indiana, special advantages for the study of the system are offered in Illinois.

History of Run-of-Mine System

Previous to 1897, there was in Illinois, a growing discontent on the part of the miners, whose earnings on the screened-coal basis failed to give satisfaction. The miners claimed, with some truth, that screens at many mines were manipulated to their disadvantage and that the spaces between the bars were widened to increase the amount of screenings. Operators gave, as an excuse for changing the screens at certain mines, that competition with other mines where the quality of coal was different from their own, justified and even necessitated such action. The men claimed further that many operators were encouraging an excessive use of powder, which again increased the quantity of screenings, as well as extorted from the miners a large portion of their wages to pay for the same.

These grievances and others led to a strong organization of the miners and the inauguration of the strike of 1897, which resulted finally in the adoption of the run-of-mine system as a basis for payment of coal mined. This agreement between the operators and miners was made law by act of the state legislature, June 3, 1897, and went into effect the first of the next month.

It proved to be, as the men hoped it would, a revolutionary movement. Some of the consequences they had foreseen, but others of equal or even greater moment were not anticipated. The output of coal increased at once from 19,786,626 tons in 1896 to 20,072,758 tons in 1897, and to 23,434,445 tons in 1899. The report of the Bureau of Labor Statistics for the year 1899, says that the adoption of the new run-of-mine system had not at that time resulted (as it has since) in a greater waste of coal.

To produce the coal mined in 1899, 419,263 kegs of powder were used, or about one keg to every 56 tons of coal. The number of fatal accidents that year was 84, against 77 in 1896; the number of men injured in 1899 was 597, against 672 in 1896. The whole number of men employed in 1899 was 36,991. Of these, 23,117 were English-speaking: American, English, Welsh, Scotch and Irish; the remainder were Germans, Italians and Poles in greatest numbers, French, Belgians, Austrians and Russians. The average price per ton received for hand-mined coal was 47c., and for machine-mined, 31c. These were the conditions after the gross-ton system had been in operation a year and a half.

Fourteen and a half years have now passed since the adoption of the system, and during this time cheap coal has had a large share in the advancement of the manufacturing interests of the state. Besides Chicago, with its more than $900,000,000 invested in manufactures, there are in Illinois no less than 30 cities where the manufactures range in value from between one and two to sixty million dollars, and these include almost everything that men can make from agricultural im-

plements to wire. The value of the manufactured products aggregate, as given in the last available report, $1,410,342,129.

Effect On Miners

In all mines in Illinois, where gas is found in dangerous quatities, and where shots of more than two pounds of powder are used, the law decrees that "shotfirers shall be employed by the company and at its expense," which would involve, $4 per day, an annual cost of about $500,000. The more intelligent miners recognize plainly that the expenditure for powder goes far to offset the higher price now paid for mining, 59c. a ton for hand mined, and 46c. for machine-mined coal, considering also the increased quantity of coal they are able to get out.

But the hours worked is as much an element of actual wage, with the miner, as the price received per ton. What with strikes and closed-down mines, the average number of days worked in 1909 was only 168, and in 1910, only 171. So much for figures; they tell much but do not make known all the conditions that the adoption of the gross-ton or run-of-mine system has developed.

The pledge made by the organization of miners in 1897, that their mining should be done in the former workmanlike manner that was possible when the coal was undercut and sheared by hand, and that the use of powder should not be inordinate, has been sadly broken. A premium has been put upon recklessness in mining. The man who used the most powder and took the greatest chances, made the most money, but produced the poorest coal; while the man who used skill in producing a larger and more marketable product and who strove to fulfill his pledge by using less powder, made less money.

This is fast bringing about a radical change in the character and class of miners employed. Experienced miners who were trained to use the pick, coming mostly from the collieries of Great Britain, and who were leaders in the movement of 1897, finding themselves now on the same financial footing or even worse than wholly untrained men from southern and southeastern Europe, a large majority of whom had never seen the inside of a mine before coming to this country, are rapidly disappearing from the state. They realize that at least one-third of the men who are nominally employed in and about the mines of the state are not miners, and should be classed as laborers. These men degrade the occupation; and good miners are making up their minds that they will be better off in every way if they find some other occupation, where better conditions prevail and work is steady.
